Contents

Preface **201**

1 Introduction **203**

1.1 AM335x Family 203

1.1.1 Device Features 203

1.1.2 Device Identification 204

1.1.3 Feature Identification 205

2 Memory Map **207**

2.1 ARM Cortex A8 Memory Map 207

2.2 ARM Cortex M3 Memory Map 216

3 ARM MPU Subsystem **219**

3.1 ARM Cortex-A8 MPU Subsystem 220

3.1.1 Features 221

3.1.2 MPU Subsystem Integration 221

3.1.3 MPU Subsystem Clock and Reset Distribution 222

3.1.4 ARM Subchip 225

3.1.5 Interrupt Controller 226

3.1.6 Power Management 226

3.1.7 ARM Programming Model 229

4 Programmable Real-Time Unit Subsystem (PRUSS) **231**

4.1 Introduction 232

4.1.1 Features 233

4.2 Integration 234

4.2.1 PRUSS Connectivity Attributes 234

4.2.2 PRUSS Clock and Reset Management 235

4.2.3 PRUSS Pin List 235

4.3 PRUSS Register Overview 237

4.3.1 Local Memory Map 237

4.3.2 Global Memory Map 238

4.4 PRUSS Internal Pinmux Overview 239

4.5 PRU 241

4.5.1 Introduction 241

4.5.2 Functional Description 243

4.5.3 Basic Programming Model 254

4.5.4 PRUSS_PRU_CTRL Registers 294

4.5.5 PRUSS_PRU_DEBUG Registers 305

4.6 Interrupt Controller 377

4.6.1 Introduction 377

4.6.2 Functional Description 378

4.6.3 Basic Programming Model 381

4.6.4 PRUSS_INTC Registers 381

4.7 Universal Asynchronous Receiver/Transmitter 449

4.7.1 Introduction 449

4.7.2 Functional Description 451

4.7.3 Registers 462

4.8 eCAP 481
4.9 CFG 481
4.9.1 PRUSS_CFG Registers 481
5 Graphics Accelerator (SGX) 501
5.1 Introduction 502
5.1.1 POWERVR SGX Main Features 502
5.1.2 SGX 3D Features 502
5.1.3 Universal Scalable Shader Engine (USSE) – Key Features 503
5.1.4 Unsupported Features 504
5.2 Integration 505
5.2.1 SGX530 Connectivity Attributes 505
5.2.2 SGX530 Clock and Reset Management 505
5.2.3 SGX530 Pin List 506
5.3 Functional Description 507
5.3.1 SGX Block Diagram 507
5.3.2 SGX Elements Description 507
6 Interrupts 509
6.1 Functional Description 509
6.1.1 Interrupt Processing 511
6.1.2 Register Protection 512
6.1.3 Module Power Saving 512
6.1.4 Error Handling 512
6.1.5 Interrupt Handling 512
6.1.6 Basic Programming Model 513
6.2 ARM Cortex A8 Interrupts 522
6.3 ARM Cortex M3 Interrupts 526
6.4 PRUSS Interrupts 528
6.5 PWM Events 530
6.6 INTC Registers 530
6.6.1 INTC_REVISION Register (offset = 0h) [reset = 0h] 537
6.6.2 INTC_SYSCONFIG Register (offset = 10h) [reset = 0h] 538
6.6.3 INTC_SYSSTATUS Register (offset = 14h) [reset = 0h] 539
6.6.4 INTC_SIR_IRQ Register (offset = 40h) [reset = 0h] 540
6.6.5 INTC_SIR_FIQ Register (offset = 44h) [reset = 0h] 541
6.6.6 INTC_CONTROL Register (offset = 48h) [reset = 0h] 542
6.6.7 INTC_PROTECTION Register (offset = 4Ch) [reset = 0h] 543
6.6.8 INTC_IDLE Register (offset = 50h) [reset = 0h] 544
6.6.9 INTC_IRQ_PRIORITY Register (offset = 60h) [reset = 0h] 545
6.6.10 INTC_FIQ_PRIORITY Register (offset = 64h) [reset = 0h] 546
6.6.11 INTC_THRESHOLD Register (offset = 68h) [reset = 0h] 547
6.6.12 INTC_ITR0 Register (offset = 80h) [reset = 0h] 548
6.6.13 INTC_MIR0 Register (offset = 84h) [reset = 0h] 549
6.6.14 INTC_MIR_CLEAR0 Register (offset = 88h) [reset = 0h] 550
6.6.15 INTC_MIR_SET0 Register (offset = 8Ch) [reset = 0h] 551
6.6.16 INTC_ISR_SET0 Register (offset = 90h) [reset = 0h] 552
6.6.17 INTC_ISR_CLEAR0 Register (offset = 94h) [reset = 0h] 553
6.6.18 INTC_PENDING_IRQ0 Register (offset = 98h) [reset = 0h] 554
6.6.19 INTC_PENDING_FIQ0 Register (offset = 9Ch) [reset = 0h] 555
6.6.20 INTC_ITR1 Register (offset = A0h) [reset = 0h] 556
6.6.21 INTC_MIR1 Register (offset = A4h) [reset = 0h] 557
6.6.22 INTC_MIR_CLEAR1 Register (offset = A8h) [reset = 0h] 558
6.6.23 INTC_MIR_SET1 Register (offset = ACh) [reset = 0h] 559
6.6.24 INTC_ISR_SET1 Register (offset = B0h) [reset = 0h] 560

7.3.2 Integration 864
7.3.3 Functional Description 866
7.3.4 Use Cases 884
7.3.5 EMIF4D Registers 884
7.3.6 DDR2/3/mDDR PHY Registers 939
7.4 ELM 948
7.4.1 Introduction 948
7.4.2 Integration 949
7.4.3 Functional Description 950
7.4.4 Basic Programming Model 953
7.4.5 ELM Registers 959
8 Power and Clock Management (PRCM) 971
8.1 Power Management and Clock Module (PRCM) 972
8.1.1 Power, Reset, Clock Module 972
8.1.2 Clock Module Registers 1017
8.1.3 Power Management Registers 1172
9 Control Module 1211
9.1 Introduction 1212
9.2 Functional Description 1212
9.2.1 Control Module Initialization 1212
9.2.2 Pad Control Registers 1212
9.2.3 EDMA Event Multiplexing 1213
9.2.4 Device Control and Status 1214
9.3 Registers 1219
9.3.1 CONTROL_MODULE Registers 1219
10 Interconnects 1321
10.1 Introduction 1322
10.1.1 Terminology 1322
10.1.2 L3 Interconnect 1322
10.1.3 L4 Interconnect 1325
11 Enhanced Direct Memory Access (EDMA) 1327
11.1 Introduction 1328
11.1.1 EDMA3 Controller Block Diagram 1328
11.1.2 Third-Party Channel Controller (TPCC) Overview 1328
11.1.3 Third-Party Transfer Controller (TPTC) Overview 1329
11.2 Integration 1331
11.2.1 Third-Party Channel Controller (TPCC) Integration 1331
11.2.2 Third-Party Transfer Controller (TPTC) Integration 1332
11.3 Functional Description 1334
11.3.1 Functional Overview 1334
11.3.2 Types of EDMA3 Transfers 1337
11.3.3 Parameter RAM (PaRAM) 1339
11.3.4 Initiating a DMA Transfer 1351
11.3.5 Completion of a DMA Transfer 1354
11.3.6 Event, Channel, and PaRAM Mapping 1355
11.3.7 EDMA3 Channel Controller Regions 1357
11.3.8 Chaining EDMA3 Channels 1359
11.3.9 EDMA3 Interrupts 1360
11.3.10 Memory Protection 1366
11.3.11 Event Queue(s) 1370
11.3.12 EDMA3 Transfer Controller (EDMA3TC) 1372
11.3.13 Event Dataflow 1375

Introduction

1.1 AM335x Family

1.1.1 Device Features

This architecture is configured with different sets of features in different devices. This technical reference manual details all of the features available in current and future AM335x devices. Some features may not be available or supported in your particular device. The features supported across different AM335x devices are shown in Table 1-1. For more information on the different packages, refer to your device-specific data manual.

Table 1-1. Device Features

Subsystem/ Co-Processor/ Peripheral	AM3352	AM3354	AM3356	AM3357	AM3358	AM3359
ARM MPU Subsystem	Y	Y	Y	Y	Y	Y
Programmable Real-Time Unit Subsystem	N	N	All features excluding EtherCAT	All features including EtherCAT	All features excluding EtherCAT	All features including EtherCAT
Graphics Accelerator (SGX)	N	Y	N	N	Y	Y
Memory Map	Y	Y	Y	Y	Y	Y
Interrupts	Y	Y	Y	Y	Y	Y

Table 1-1. Device Features (continued)

Subsystem/ Co-Processor/ Peripheral	AM3352	AM3354	AM3356	AM3357	AM3358	AM3359
Multimedia Card (MMC)	Y	Y	Y	Y	Y	Y
Universal Asynchronous Receiver/Transmitter (UART)	Y	Y	Y	Y	Y	Y
DMTimer	Y	Y	Y	Y	Y	Y
DMTimer 1ms	Y	Y	Y	Y	Y	Y
RTCSS	Y	Y	Y	Y	Y	Y
Watchdog	Y	Y	Y	Y	Y	Y
I2C	Y	Y	Y	Y	Y	Y
Multichannel Audio Serial Port (McASP)	Y	Y	Y	Y	Y	Y
Controller Area Network (CAN)	Y	Y	Y	Y	Y	Y
Multichannel Serial Port Interface (McSPI)	Y	Y	Y	Y	Y	Y
General Purpose Input/Output (GPIO)	Y	Y	Y	Y	Y	Y
Initialization	Y	Y	Y	Y	Y	Y

1.1.2 Device Identification

Several registers help identify the type and available features of the device. Table 1-2 and Table 1-3 summarize these registers.

Table 1-2. Device_ID (Address 0x44E10600) Bit Field Descriptions

Bit	Field	Value	Description
31-28	DEVREV		Device revision See AM335x errata for specific information on each revision.
		0	1st revision
		1	2nd revision
		n	*n*-th revision
27-12	PARTNUM		Device part number 0xB944
11-1	MFGR		Manufacturer's ID 0x017
0	Reserved		Read always as 0 0x0

Table 1-3. Device ID Register Values

Silicon Type	Bit Field	Value	Description
AM335x ES1.0	DEVICE_ID[31:0]	0x0B94402E	1st revision silicon
AM335x ES1.1	DEVICE_ID[31:0]	0x1B94402E	2nd revision silicon

1.1.3 Feature Identification

The AM335x has many different feature sets available. The DEV_FEATURE register in the control module identifies which features are available in each device in the AM335x family. See Section 9.3.1.16, *dev_feature Register*, in the control module chapter for more information on the bits in the DEV_FEATURE register.

ARM MPU Subsystem

This chapter describes the MPU Subsystem for the device.

Topic **Page**

3.1 ARM Cortex-A8 MPU Subsystem 220

Copyright © 2011, Texas Instruments Incorporated

3.1 ARM Cortex-A8 MPU Subsystem

The Microprocessor Unit (MPU) subsystem of the device handles transactions between the ARM core (ARM® Cortex™-A8 Processor), the L3 interconnect, and the interrupt controller (INTC). The MPU subsystem is a hard macro that integrates the ARM® Cortex™-A8 Processor with additional logic for protocol conversion, emulation, interrupt handling, and debug enhancements.

Cortex™-A8 is an ARMv7 compatible, dual-issue, in-order execution engine with integrated L1 and L2 caches with NEON™ SIMD Media Processing Unit.

An Interrupt Controller is included in the MPU subsystem to handle host interrupt requests in the system.

The MPU subsystem includes CoreSight compliant logic to allow the Debug Sub-system access to the CortexA8 debug and emulation resources, including the Embedded Trace Macrocell.

The MPU subsystem has three functional clock domains, including a high-frequency clock domain used by the Cortex™-A8. The high-frequency domain is isolated from the rest of the system by asynchronous bridges.

Figure 3-1 shows the high-level block diagram of the MPU subsystem.

Figure 3-1. Microprocessor Unit (MPU) Subsystem

3.1.1 Features

This section outlines the key features of the MPU subsystem:

- ARM Microprocessor
  - CortexA8
  - ARM Architecture version 7 ISA.
  - 2-issue, in-order execution pipeline.
  - L1 and L2 Instruction and Data Cache of 32 KB , 4-way, 16 word line with 128 bit interface.
  - Integrated L2 cache of 256 KB, 8-way, 16 word line, 128 bit interface to L1 along with ECC/Parity supported.
  - Includes the Neon Media coprocessor (NEON™) which implements the Advanced SIMD media processing architecture.
  - Includes the VFP coprocessor which implements the VFPv3 architecture and is fully compliant with IEEE 754 standard.
  - The external interface uses the AXI protocol configured to 128-bit data width.
  - Includes the Embedded Trace Macrocell (ETM) support for non-invasive debugging.
  - Implements the ARMv7 debug with watch-point and breakpoint registers and 32-bit Advanced Peripheral Bus (APB) slave interface to CoreSight debug systems.
- AXI2OCP Bridge
  - Support OCP 2.2.
  - Single Request Multiple Data Protocol on two ports.
  - Multiple targets, including three OCP ports (128-bit, 64-bit and 32-bit).
- Interrupt Controller
  - Support up to 128 interrupt requests
- Emulation/Debug
  - Compatible with CoreSight Architecture.
- Clock Generation
  - Through PRCM
- DFT
  - Integrated PBIST controller to test L2 tag and data ram, L1I and L1D data ram and OCM RAM.

3.1.2 MPU Subsystem Integration

The MPU subsystem integrates the following group of submodules:

ARM® Cortex™-A8 Processor: Provides a high processing capability, including the NEON technology for mobile multimedia acceleration. The ARM communicates through an AXI bus with the AXI2OCP bridge and receives interrupts from the MPU subsystem interrupt controller (MPU INTC).

Interrupt controller: Handles the module interrupts (for details, see the Interrupt Controller chapter).

AXI2OCP bridge: Allows communication between the ARM (AXI), the INTC (OCP), and the modules (OCP L3).

I2Async bridge: This is an asynchronous bridge interface providing an asynchronous OCP to OCP interface. This interface is between the AXI2OCP bridge within the MPU subsystem and the T2Async bridge external to the MPU subsystem.

Clock Divider: Provides the required divided clocks to the internal modules of the MPU subsystem and has a clock input from SYSCLK2 which is fed by the power, reset, and clock management (PRCM) module of the device.

In-Circuit Emulator: It is fully Compatible with CoreSight Architecture and enables debugging capabilities.

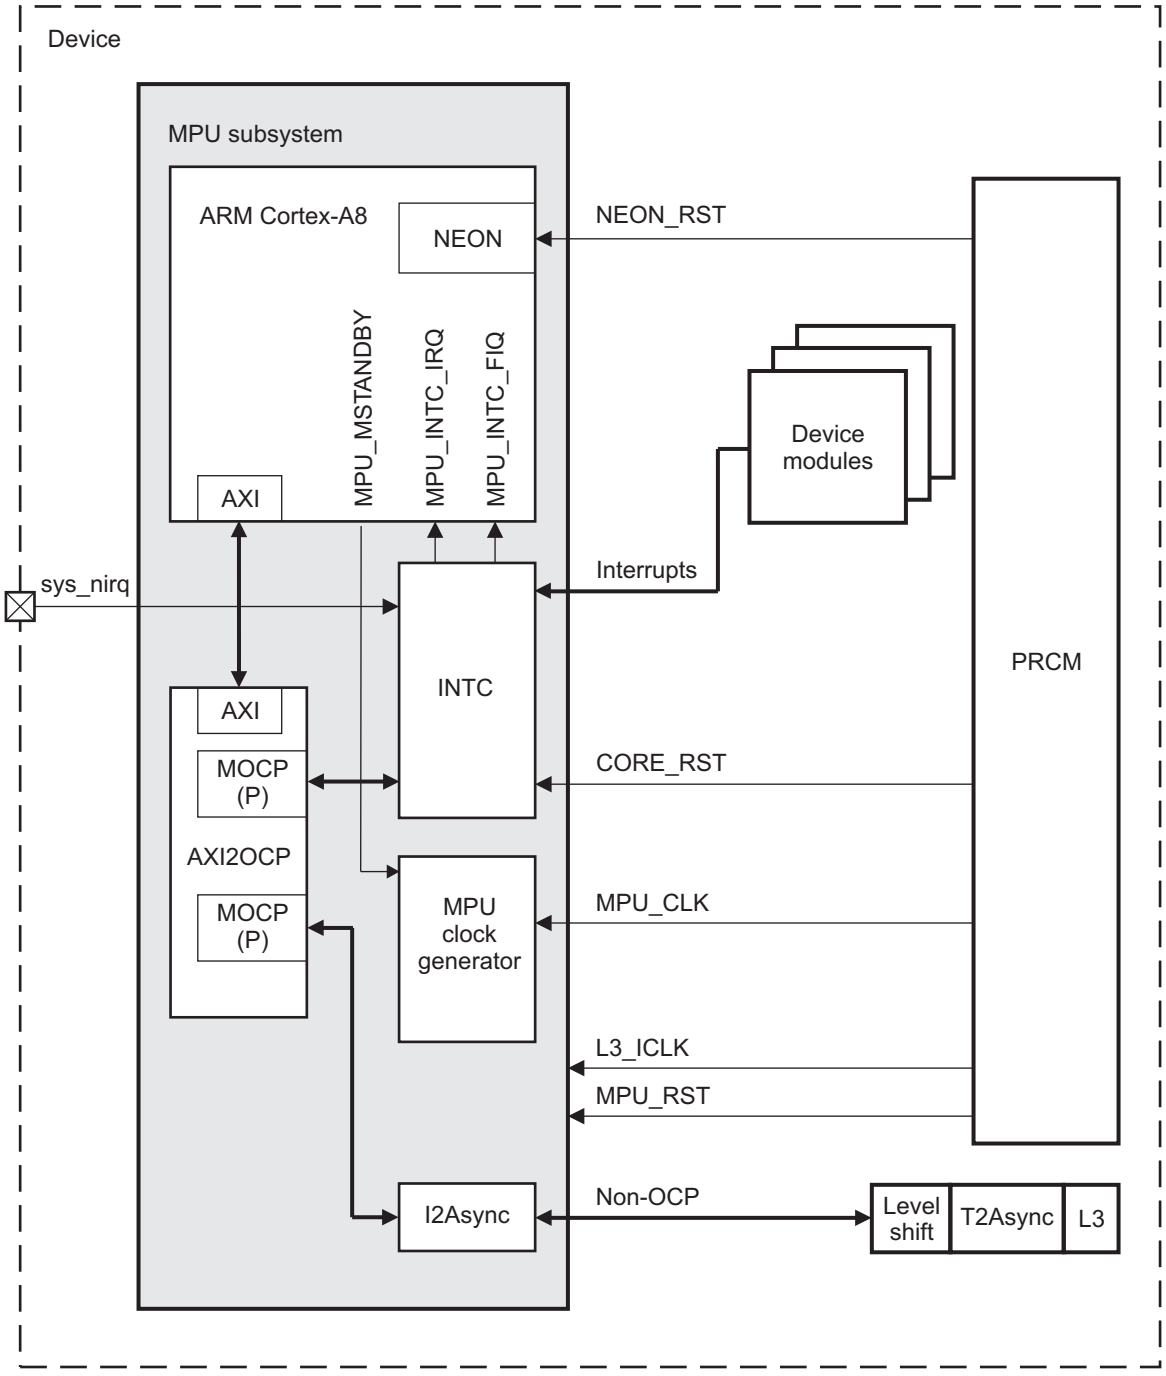

Figure 3-2. Microprocessor Unit (MPU) Subsystem Signal Interface

3.1.3 MPU Subsystem Clock and Reset Distribution

3.1.3.1 Clock Distribution

The MPU subsystem includes an embedded DPLL which sources the clock for the ARM Cortex-A8 processor. A clock divider within the subsystem is used for deriving the clocks for other internal modules.

Copyright © 2011, Texas Instruments Incorporated

All major modules inside the MPU subsystem are clocked at half the frequency of the ARM core. The divider of the output clock can be programmed with the PRCM.CM_CLKSEL2_PLL_MPU[4:0]MPU_DPLL_CLKOUT_DIV register field, the frequency is relative to the ARM core. For details see the Power, Reset, and Clock Management (PRCM) chapter.

The clock generator generates the following functional clocks:

ARM (ARM_FCLK): This is the core clock. It is the base fast clock that is routed internally to the ARM logic and internal RAMs, including NEON, L2 cache, the ETM core (emulation), and the ARM core.

AXI2OCP Clock (AXI_FCLK): This clock is half the frequency of the ARM clock (ARM_FCLK). The OCP interface thus performs at one half the frequency of ARM.

Interrupt Controller Functional Clock (MPU_INTC_FCLK): This clock, which is part of the INTC module, is half the frequency of the ARM clock (ARM_FCLK).

ICE-Crusher Functional Clock (ICECRUSHER_FCLK): ICE-Crusher clocking operates on the APB interface, using the ARM core clocking. This clock is half the frequency of the ARM clock (ARM_FCLK).

I2Async Clock (I2ASYNC_FCLK): This clock is half the frequency of the ARM clock (ARM_FCLK). It matches the OCP interface of the AXI2OCP bridge.

NOTE: The second half of the asynchronous bridge (T2ASYNC) is clocked directly by the PRCM with the core clock. T2ASYNC is not part of the MPU subsystem.

Emulation Clocking: Emulation clocks are distributed by the PRCM module and are asynchronous to the ARM core clock (ARM_FCLK) and can run at a maximum of 1/3 the ARM core clock.

Table Table 3-1 and summarizes the clocks generated in the MPU subsystem by the MPU clock generator.

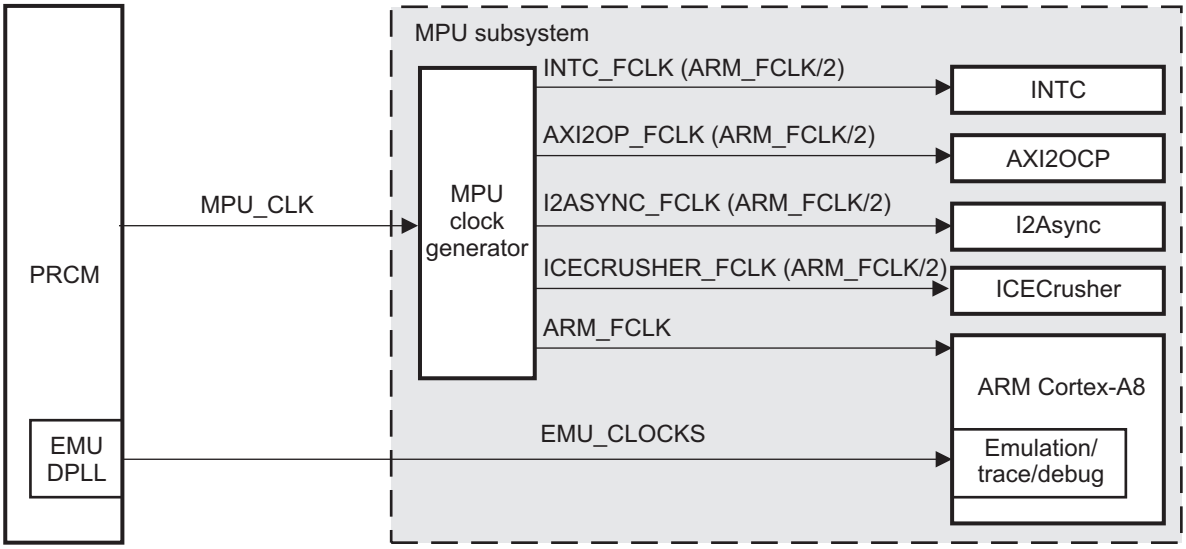

Figure 3-3. MPU Subsystem Clocking Scheme

Table 3-1. MPU Subsystem Clock Frequencies

Clock signal	Frequency
Cortex A8 Core Functional Clock	MPU_CLK
AXI2OCP Bridge Functional Clock	MPU_CLK / 2
Device Clock	MPU_CLK / 2
I2Async Bridge Functional Clock	MPU_CLK / 2

Copyright © 2011, Texas Instruments Incorporated

3.1.3.2 Reset Distribution

Resets to the MPU subsystem are provided by the PRCM and controlled by the clock generator module.

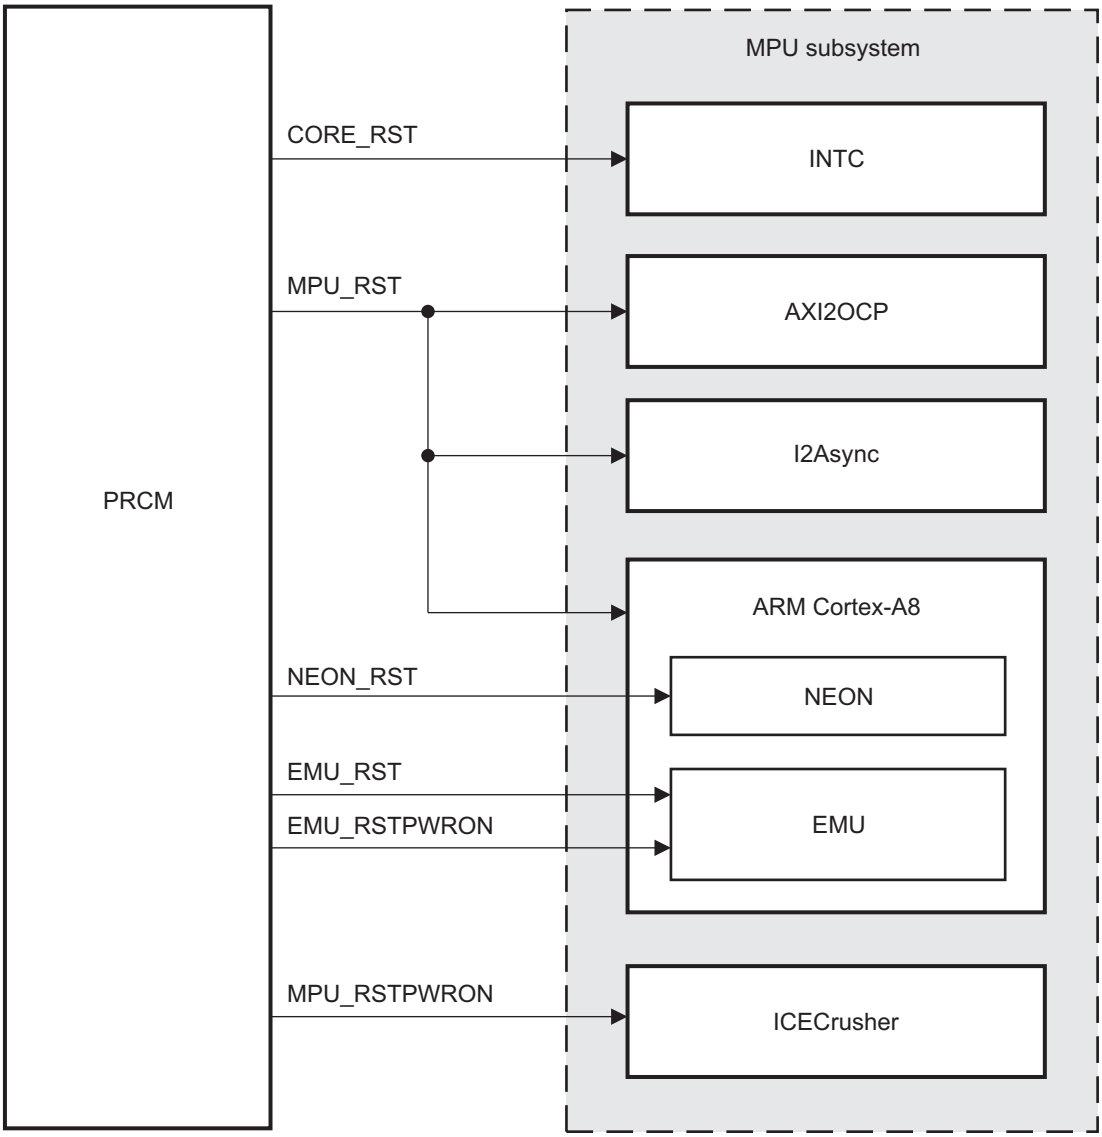

Figure 3-4. Reset Scheme of the MPU Subsystem

Table 3-2. Reset Scheme of the MPU Subsystem

Signal Name	I/O	Interface
MPU_RST	I	PRCM
NEON_RST	I	PRCM

For details about clocks, resets, and power domains, see the Power, Reset, and Clock Management (PRCM) chapter.

3.1.4 ARM Subchip

3.1.4.1 ARM Overview

The ARM Cortex-A8 processor incorporates the technologies available in the ARM7™ architecture. These technologies include NEON™ for media and signal processing and Jazelle™ RCT for acceleration of realtime compilers, Thumb®-2 technology for code density and the VFPv3 floating point architecture. For details, see the ARM ® Cortex™-A8 Technical Reference Manual.

3.1.4.2 ARM Description

3.1.4.2.1 ARM® Cotrex™-A8 Instruction, Data, and Private Peripheral Port

The AXI bus interface is the main interface to the ARM system bus. It performs L2 cache fills and non-cacheable accesses for both instructions and data. The AXI interface supports 128bit and 64-bit wide input and output data buses. It supports multiple outstanding requests on the AXI bus and a wide range of bus clock to core clock ratios. The bus clock is synchronous with the core clock.

See the ARM ® Cortex™-A8 Technical Reference Manual for a complete programming model of the transaction rules (ordering, posting, and pipeline synchronization) that are applied depending on the memory region attribute associated with the transaction destination address.

3.1.4.2.2 ARM Core Supported Features

Table Table 3-3 below provides a list of main functions of the Cortex™-A8 core supported inside the MPU Subsystem.

Table 3-3. ARM Core Supported Features

Features	Comments
ARM version 7 ISA	Standard ARM instruction set + Thumb2™, JazelleX™ Java accelerator, and Media extensions.
	Backward compatible with previous ARM ISA versions.
L1 Icache and Dcache	32 KB , 4-way, 16 word line, 128 bit interface.
L2 Cache	256 KB, 8-way, 16 word line, 128 bit interface to L1, ECC/Parity is supported. The L2 cache and cache controller are embedded within the ARM core.
	L2 valid bits cleared by software loop or by hardware.
TLB	Fully associative and separate ITLB with 32 entries and DTLB with 32 entries.
CoreSight ETM	The CoreSight ETM is embedded with the ARM core. The 32KB buffer (ETB) exists at the Chip Level (DebugSS)
Branch Target Address Cache	512 entries
Enhanced Memory Management Unit	Mapping sizes are 4KB, 64KB, 1MB, and 16MB. (ARM MMU adds extended physical address ranges)
Neon	Gives greatly enhanced throughput for media workloads and VFP-Lite support.
Flat Memories	176 Kbytes of ROM
	64 Kbytes of RAM
Buses	128 bit AXI internal bus from CortexA8 routed by an AXI2OCP bridge to the interrupt controller, ROM, RAM, and 3 asynchronous OCP bridges (128 bits, and 64 bits)
Low interrupt latency	Closely coupled INTC to the ARM core with 128 interrupt lines
Vectored Interrupt Controller Port	Present.
JTAG based debug	Supported via DAP
Trace support	Supported via TPIU

Copyright © 2011, Texas Instruments Incorporated

Table 3-3. ARM Core Supported Features (continued)

Features	Comments
External Coprocessor	Not supported

For more information, see the ARM® Cortex™-A8 Technical Reference Manual.

3.1.5 Interrupt Controller

The Host ARM Interrupt Controller (AINTC) is responsible for prioritizing all service requests from the system peripherals and generating either nIRQ or nFIQ to the host. The type of the interrupt (nIRQ or nFIQ) and the priority of the interrupt inputs are programmable. The AINTC interfaces to the ARM processor via the AXI port through an AXI2OCP bridge and runs at half the processor speed. It has the capability to handle up to 128 requests which can be steered/prioritized as A8 nFIQ or nIRQ interrupt requests.

The general features of the AINTC are:

- Up to 128 level sensitive interrupts inputs
- Individual priority for each interrupt input
- Each interrupt can be steered to nFIQ or nIRQ
- Independent priority sorting for nFIQ and nIRQ

3.1.6 Power Management

3.1.6.1 Power Domains

The MPU subsystem is divided into 5 power domains controlled by the PRCM, as shown in Figure Figure 3-5.

NOTE: The emulation domain and the core domain are not fully embedded in MPU subsystem.

Copyright © 2011, Texas Instruments Incorporated

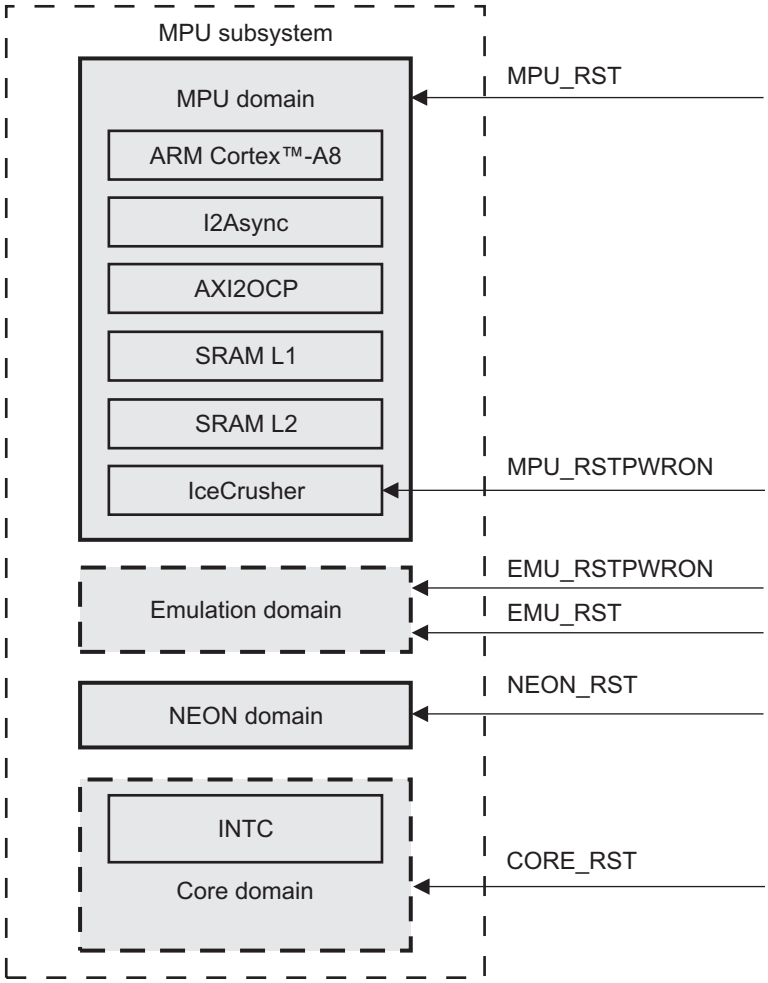

Figure 3-5. MPU Subsystem Power Domain Overview

Power management requirements at the device level govern power domains for the MPU subsystem. The device-level power domains are directly aligned with voltage domains and thus can be represented as a cross reference to the different voltage domains.

Table Table 3-4 shows the different power domains of the MPU subsystem and the modules inside.

Table 3-4. Overview of the MPU Subsystem Power Domain

Functional Power Domain	Physical Power Domain per System/Module
MPU subsystem domain	ARM, AXI2OCP, I2Asynch Bridge, ARM L1 and L2 periphery logic and array, ICE-Crusher, ETM, APB modules
MPU NEON domain	ARM NEON accelerator
CORE domain	MPU interrupt controller
EMU domain	EMU (ETB,DAP)

Copyright © 2011, Texas Instruments Incorporated

NOTE: L1 and L2 array memories have separate control signals into the in MPU Subsystem, thus directly controlled by PRCM For details on the physical power domains and the voltage domains, see the Power, Reset, and Clock Management (PRCM) chapter.

3.1.6.2 Power States

Each power domain can be driven by the PRCM in 4 different states, depending on the functional mode required by the user.

For each power domain the PRCM manages all transitions by controlling domain clocks, domain resets, domain logic power switches and memory power switches.

Table 3-5. MPU Power States

Power State	Logic Power	Memory Power	Clocks
Active	On	On or Off	On (at least one clock)
Inactive	On	On or Off	Off
Off	Off	Off	Off (all clocks)

3.1.6.3 Power Modes

The major part of the MPU subsystem belongs to the MPU power domain. The modules inside this power domain can be off at a time when the ARM processor is in an OFF or standby mode. IDLE/WAKEUP control is managed by the clock generator block but initiated by the PRCM module.

The MPU Standby status can be checked with PRCM.CM_IDLEST_MPU[0] ST_MPU bit. For the MPU to be on, the core (referred here as the device core) power must be on. Device power management does not allow INTC to go to OFF state when MPU domain is on (active or one of retention modes).

The NEON core has independent power off mode when not in use. Enabling and disabling of NEON can be controlled by software.

CAUTION

The MPU L1 cache memory does not support retention mode, and its array switch is controlled together with the MPU logic. For compliance, the L1 retention control signals exist at the PRCM boundary, but are not used. The ARM L2 can be put into retention independently of the other domains.

Table Table 3-6 outlines the supported operational power modes. All other combinations are illegal. The ARM L2, NEON, and ETM/Debug can be powered up/down independently. The APB/ATB ETM/Debug column refers to all three features: ARM emulation, trace, and debug.

The MPU subsystem must be in a power mode where the MPU power domain, NEON power domain, debug power domain, and INTC power domain are in standby, or off state.

Copyright © 2011, Texas Instruments Incorporated

Table 3-6. MPU Subsystem Operation Power Modes

Mode	MPU and ARM Core Logic	ARM L2 RAM	NEON INTC	Device Core and ETM	APB/ATB Debug
1	Active	Active	Active	Active	Disabled or enabled
2	Active	Active	OFF	Active	Disabled or enabled
3	Active	RET	Active	Active	Disabled or enabled
4	Active	RET	OFF	Active	Disabled or enabled
5	Active	OFF	Active	Active	Disabled or enabled
6	Active	OFF	OFF	Active	Disabled or enabled
7	OFF	RET	OFF	OFF	Disabled or enabled
8	Standby	Active	Standby	Active	Disabled or enabled
9	Standby	Active	OFF	Active	Disabled or enabled
10	Standby	RET	Standby	Active	Disabled or enabled
11	Standby	RET	OFF	Active	Disabled or enabled
12	Standby	OFF	Standby	Active	Disabled or enabled
13	Standby	OFF	OFF	Active	Disabled or enabled
14	OFF	OFF	OFF	OFF	Disabled or enabled

3.1.7 ARM Programming Model

For detailed descriptions of registers used for MPU configuration, see the Power, Reset, and Clock Management, and the Interrupt Controller chapters.

3.1.7.1 Clock Control

For clock configuration settings, see the Power, Reset, and Clock Management (PRCM) chapter

3.1.7.2 MPU Power Mode Transitions

The following subsections describe transitions of different power modes for MPU power domain:

- Basic power on reset
- MPU into standby mode
- MPU out of standby mode
- MPU power on from a powered off state

3.1.7.2.1 Basic Power-On Reset

The power-on reset follows the following sequence of operation and is applicable to initial power-up and wakeup from device off mode:

Reset the INTC (CORE_RST) and the MPU subsystem modules (MPU_RST). The clocks must be active during the MPU reset and CORE reset.

3.1.7.2.2 MPU Into Standby Mode

The MPU into standby mode follows the following sequence of operation and is applicable to initial power-up and wakeup from device Off mode.

1. The ARM core initiates entering into standby via software only (CP15 - WFI).
2. MPU modules requested internally of MPU subsystem to enter idle, after ARM core standby detected.
3. MPU is in standby output asserted for PRCM (all outputs guaranteed to be at reset values).
4. PRCM can now request INTC to enter into idle mode. Acknowledge from INTC goes to PRCM.

NOTE: The INTC SWAKEUP output is a pure hardware signal to PRCM for the status of its IDLE request and IDLE acknowledge handshake.

Copyright © 2011, Texas Instruments Incorporated

NOTE: In debug mode, ICE-Crusher could prevent MPU subsystem from entering into IDLE mode.

3.1.7.2.3 MPU Out Of Standby Mode

The MPU out of standby mode follows the following sequence of operation and is applicable to initial power-up and wakeup from device Off mode.

1. PRCM must start clocks through DPLL programming.
2. Detect active clocking via status output of DPLL.
3. Initiate an interrupt through the INTC to wake up the ARM core from STANDBYWFI mode.

3.1.7.2.4 MPU Power On From a Powered-Off State

1. MPU Power On, NEON Power On, Core Power On (INTC) should follow the ordered sequence per power switch daisy chain to minimize the peaking of current during power-up.

   NOTE: The core domain must be on, and reset, before the MPU can be reset.

2. Follow the reset sequence as described in the Basic Power-On Reset section.

3.1.7.3 NEON Power Mode Transition

When NEON power domain transition is configured to Automatic Hardware-supervised mode (CM_CLKSTCTRL_NEON[1:0] CLKTRCTRL_NEON bits are set to 0x3), it can not transition into idle unless MPU goes into Standby, because of the Hardware Sleep dependency between NEON and the MPU domain.

In that case, the MPU domain must also be configured in Automatic Hardware Supervised mode (CM_CLKSTCTRL_MPU[1:0] CLKTRCTRL_MPU bits must be set to 0x3) for the NEON power domain transition to happen.

For the complete programming model, see the ARM® Cortex™-A8 Technical Reference Manual.

4.1 Introduction

The Programmable Real-time Unit Subsystem (PRUSS) consists of dual 32-bit RISC cores (Programmable Real-Time Units, or PRUs), shared, data, and instruction memories, internal peripheral modules, and an interrupt controller (INTC). The programmable nature of the PRUs, along with their access to pins and events, provide flexibility in implementing custom peripheral interfaces, fast real-time responses, power saving techniques, specialized data handling and DMA operations, and in offloading tasks from the other processor cores of the system-on-chip (SoC).

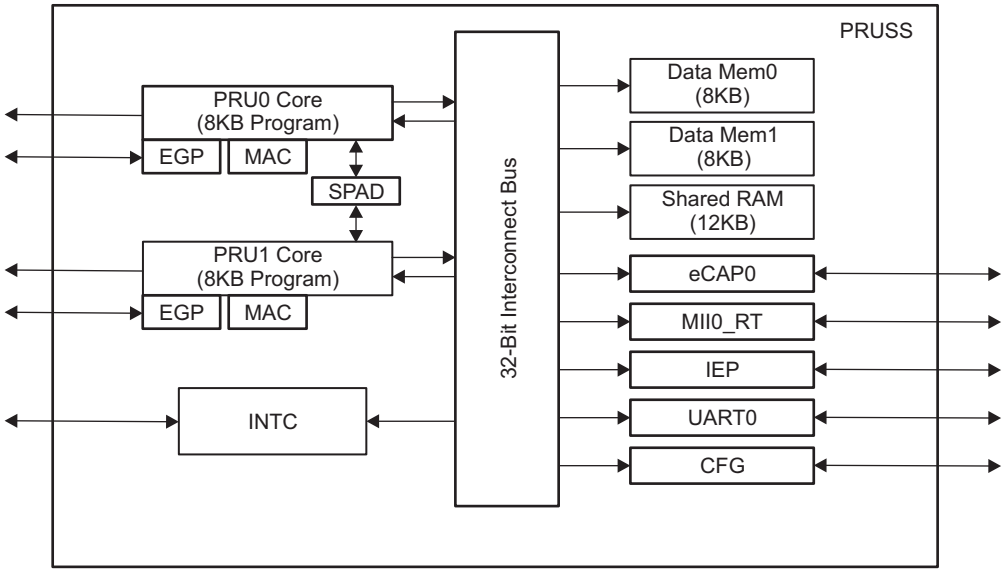
Figure 4-1 shows the PRUSS details. The subsystem available on this device is the next-generation PRUSS (PRUSSv2). Compared to the previous generation available on AM1x and OMAP-L13x, this version includes the following enhancements:

- Additional data memory (8 KB compared with 512 B) and instruction memory (8 KB compared with 4 KB)
- 12 KB Shared RAM
- Enhanced GPIO (EGPIO), adding serial, parallel, and MII capture of the PRU input/output pins
- Scratch pad (SPAD) shared by the PRU cores
- Multiplier with optional accumulation (MAC)
- Internal peripheral modules (UART, eCAP, MII_RT, MDIO, and IEP)

Similar to the previous generation, the PRUs have access to all resources on the SoC through the Interface/OCP master port, and the external host processors can access the PRUSS resources through the Interface/OCP Master port. The Switched Central Resource (SCR) connects the various internal and external masters to the resources inside the PRUSS. The INTC handles system input events and posts events back to the device-level host CPU.

The PRU cores are programmed with a small, deterministic instruction set. Each PRU can operate independently or in coordination with each other and can also work in coordination with the device-level host CPU. This interaction between processors is determined by the nature of the firmware loaded into the PRU's instruction memory.

Figure 4-1. Block Diagram



The subsystem available on this device is the next-generation PRUSS (PRUSSv2).

Copyright © 2011, Texas Instruments Incorporated

4.1.1 Features

The PRU subsystem includes the following main features:

- Two PRUs each with:
  - 8KB program memory
  - 8KB data memory
  - High Performance Interface/OCP Master port for accessing external memories
  - Enhanced GPIO (EGPIO) with async capture and serial support
  - Multiplier with optional accumulation (MAC)
- One scratch pad (SPAD) memory and broadside direct connect
  - 3 Banks of 30 32-bit registers
- 12 KB general purpose shared memory
- One Interrupt Controller (INTC)
  - Up to 64 input events supported
  - Interrupt mapping to 10 interrupt channels
  - 10 Host interrupts (2 to PRU0 and PRU1, 8 output to chip level)
  - Each system event can be enabled and disabled
  - Each host event can be enabled and disabled
  - Hardware prioritization of events
- 16 software Events generation by 2 PRUs
- One Ethernet MII_RT module with 2 MII ports and configurable connections to PRUs*
- One MDIO Port*
- One Industrial Ethernet Peripheral (IEP) to manage/generate Industrial Ethernet functions*
  - 1 Industrial Ethernet timer with 7/9 capture and 8 compare events
  - 2 Industrial Ethernet sync signals
  - 2 Industrial Ethernet 16-bit watchdog timers
  - Industrial Ethernet digital IOs
- One 16550-compatible UART with a dedicated 192-MHz clock
- One Enhanced Capture Module (ECAP)
- Flexible power management support
- Integrated switched central resource (SCR) bus for connecting the various internal and external masters to the resources inside the PRUSS
- Interface/OCP Slave port for external masters to access PRUSS memories
- Optional address translation for PRU transaction to External Host
- All memories within the PRUSS support parity

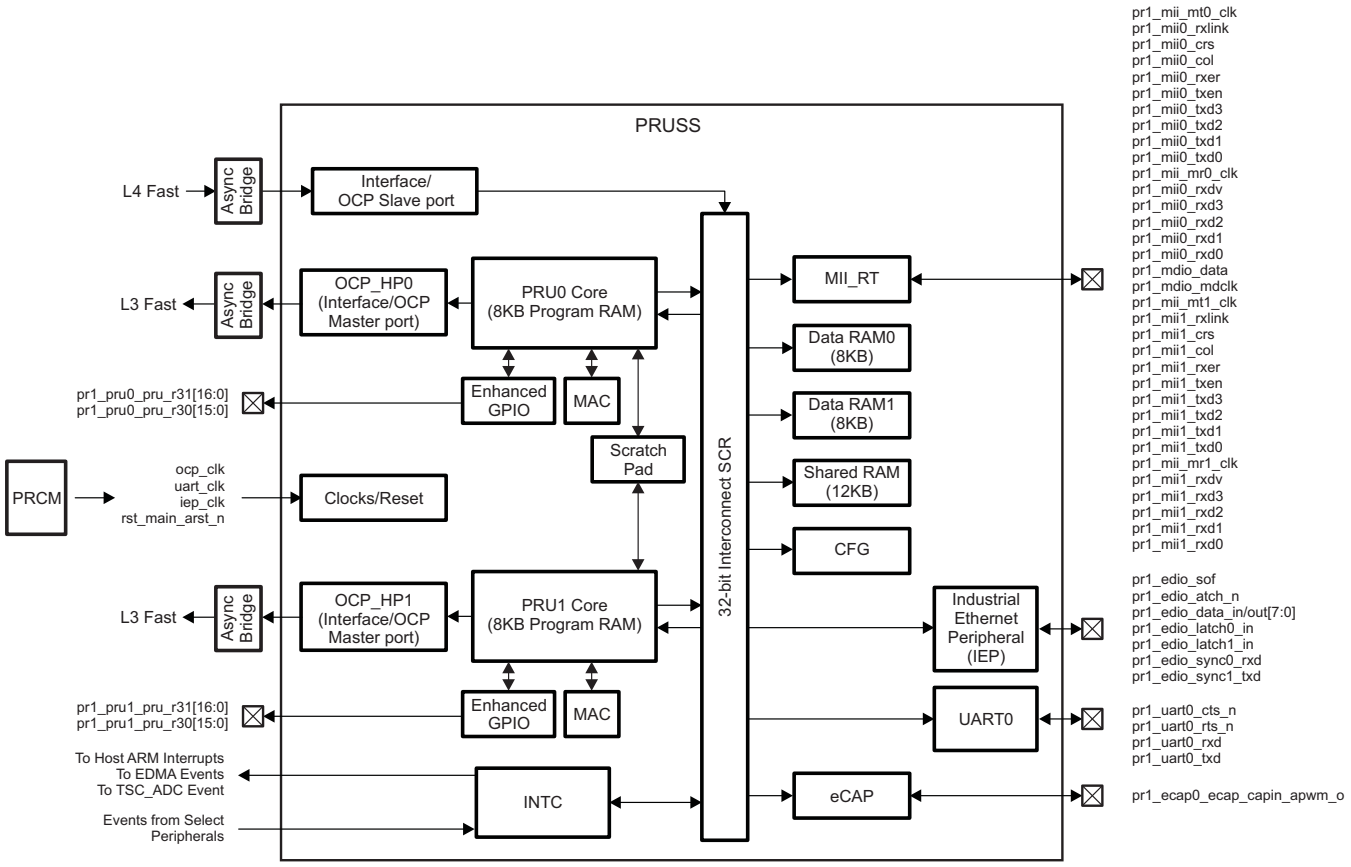
NOTE: * — Module is used by EtherCAT. See the device matrix in Chapter 1 for availability of EtherCAT and these features.

Copyright © 2011, Texas Instruments Incorporated

4.2 Integration

The device includes a programmable real-time unit subsystem (PRUSS) consisting of two independent Programmable Real-time Units (PRUs). Each PRU is a 32-bit Load/Store RISC processor with dedicated memories. The PRUSS integration is shown in Figure 4-2.

Figure 4-2. PRUSS Integration



See the device matrix in Chapter 1 for availability of all features.

4.2.1 PRUSS Connectivity Attributes

The general connectivity attributes for the PRU subsystem are shown in Table 4-1.

Table 4-1. PRUSS Connectivity Attributes

Attributes	Type
Power Domain	Peripheral Domain
Clock Domain	PD_PER_PRUSS_OCP_GCLK (OCP clock) PD_PER_PRUSS_IEP_GCLK (IEP clock) PD_PER_PRUSS_UART_GCLK (UART clock)
Reset Signals	PRUSS_LRST_N
Idle/Wakeup Signals	Standby Idle
Interrupt Requests	8 Interrupts pr1_host_intr[7:1](1) to MPU Subsystem pr1_host_intr[0](1) to MPU Subsystem and TSC_ADC
DMA Requests	No dedicated DMA events but pr1_host_intr[7:6](1) interrupt outputs also connected as DMA events
Physical Address	L4 Fast Slave Port

(1) pr1_host_intr[0:7] corresponds to Host-2 to Host-9 of the PRUSS INTC.

Copyright © 2011, Texas Instruments Incorporated

4.2.2 PRUSS Clock and Reset Management

The PRUSS module uses the following functional and OCP interface clocks.

Table 4-2. PRUSS Clock Signals

Clock Signal	Max Freq	Reference / Source	Comments
l3_clk Interface Clock	200 MHz	CORE_CLKOUTM4 or Display PLL CLKOUT	pd_per_pruss_ocp_gclk from PRCM Clocks both L3 master and L4F slave
uart_clk Functional Clock	192 MHz	PER_CLKOUTM2	pd_per_pruss_uart_gclk from PRCM UART Clock
iep_clk Functional Clock	200 MHz	CORE_CLKOUTM4	pd_per_pruss_iep_gclk from PRCM Industrial Ethernet Peripheral Clock

4.2.3 PRUSS Pin List

The PRUSS external interface signals are shown in Table 4-3. The PRUSS has a large number of available I/O signals. Most of these are multiplexed with other functional signals at the chip level. Please refer to the device's System Reference Guide or datasheet for specific signal availability through pin muxing.

Table 4-3. PRUSS Pin List

Pin	Type	Description
pr1_mii_mr0_clk	I	MII0 Receive Clock
pr1_mii0_rxdv	I	MII0 Receive Data Valid

4.3 PRUSS Register Overview

The PRUSS comprises various distinct addressable regions that are mapped to both a local and global memory map. The local memory maps are maps with respect to the PRU point of view. The global memory maps are maps with respect to the Host point of view, but can also be accessed by the PRUSS.

4.3.1 Local Memory Map

The PRUSS memory map is documented in Table 4-4 (Instruction Space) and in Table 4-5 (Data Space). Note that these two memory maps are implemented inside the PRUSS and are local to the components of the PRUSS.

4.3.1.1 Local Instruction Memory Map

Each PRU has a dedicated 8KB of Instruction Memory which needs to be initialized by a Host processor before the PRU executes instructions. This region is only accessible to masters via the interface/ OCP slave port when the PRU is not running.

Table 4-4. Local Instruction Memory Map

Start Address	PRU0	PRU1
0x0000_0000	8KB IRAM	8KB IRAM

4.3.1.2 Local Data Memory Map

The local data memory map in Table 4-5 allows each PRU core to access the PRUSS addressable regions and the external host's memory map.

The PRU accesses the external Host memory map through the Interface/OCP Master port (System OCP_HP0/1) starting at address 0x0008_0000. By default, memory addresses between 0x0000_0000 – 0x0007_FFFF will correspond to the PRUSS local address in Table 4-5. To access an address between 0x0000_0000–0x0007_FFFF of the external Host map, the address offset of –0x0008_0000 feature is enabled through the PMAO register of the PRUSS CFG register space.

Table 4-5. Local Data Memory Map

Start Address	PRU0	PRU1
0x0000_0000	Data 8KB RAM 0(1)	Data 8KB RAM 1(1)
0x0000_2000	Data 8KB RAM 1(1)	Data 8KB RAM 0(1)
0x0001_0000	Data 12KB RAM2 (Shared)	Data 12KB RAM2 (Shared)
0x0002_0000	INTC	INTC
0x0002_2000	PRU0 Control Registers	PRU0 Control Registers
0x0002_2400	Reserved	Reserved
0x0002_4000	PRU1 Control	PRU1 Control
0x0002_4400	Reserved	Reserved
0x0002_6000	CFG	CFG
0x0002_8000	UART 0	UART 0
0x0002_A000	Reserved	Reserved
0x0002_C000	Reserved	Reserved
0x0002_E000	IEP	IEP
0x0003_0000	eCAP 0	eCAP 0
0x0003_2000	MII_RT_CFG	MII_RT_CFG
0x0003_2400	MII_MDIO	MII_MDIO
0x0003_4000	Reserved	Reserved
0x0003_8000	Reserved	Reserved

(1) When PRU0 accesses Data RAM0 at address 0x00000000, PRU1 also accesses Data RAM1 at address 0x00000000. Data RAM0 is intended to be the primary data memory for PRU0 and Data RAM1 for PRU1. However, for passing information between PRUs, each PRU can access the data ram of the other PRU at address 0x0001_0000.

Copyright © 2011, Texas Instruments Incorporated

Table 4-5. Local Data Memory Map (continued)

Start Address	PRU0	PRU1
0x0004_0000	Reserved	Reserved
0x0008_0000	System OCP_HP0	System OCP_HP1

4.3.2 Global Memory Map

The global view of the PRUSS internal memories and control ports is shown in Table 4-6. The offset addresses of each region are implemented inside the PRUSS but the global device memory mapping places the PRUSS slave port in the address range shown in the external Host top-level memory map.

The global memory map is with respect to the Host point of view, but it can also be accessed by the PRUSS. Note that PRU0 and PRU1 can use either the local or global addresses to access their internal memories, but using the local addresses will provide access time several cycles faster than using the global addresses. This is because when accessing via the global address the access needs to be routed through the switch fabric outside PRUSS and back in through the PRUSS slave port.

Each of the PRUs can access the rest of the device memory (including memory mapped peripheral and configuration registers) using the global memory space addresses. See Chapter 6, *Memory Map*, for base addresses of each module in the device.

Table 4-6. Global Memory Map

Offset Address	PRUSS
0x0000_0000	Data 8KB RAM 0
0x0000_2000	Data 8KB RAM 1
0x0001_0000	Data 12KB RAM 2 (Shared)
0x0002_0000	INTC
0x0002_2000	PRU0 Control
0x0002_2400	PRU0 Debug
0x0002_4000	PRU1 Control

0x0003_8000	PRU1 8KB IRAM
0x0004_0000	Reserved

Copyright © 2011, Texas Instruments Incorporated

4.4 PRUSS Internal Pinmux Overview

The PRUSS supports an internal pinmux selection option that expands the device-level pinmuxing. The internal pinmuxing is programmable through the PIN_MX register of the PRUSS CFG register space.

The pin_mux_sel[0] determines the external signals routed to the internal input signals, mii0_rxd[3:0]. The pin_mux_sel[1] determines the internal output signals routed to the external signals, pr1_pru0_pru_r30[13:8], and the external signals routed to the internal input signals, pru0_r30[5:0].

Note: pin_mux_sel[x] = 0 is always the standard pin mapping (default).

Table 4-7. PRUSS Internal Signal Muxing: pin_mux_sel[0]

	pin_mux_sel[0] = 1	**pin_mux_sel[0] = 0**
Internal PRUSS Signal Name	**External Chip Level Signal Name**

4.5 PRU

4.5.1 Introduction

The PRU is a processor optimized for performing embedded tasks that require manipulation of packed memory mapped data structures, handling of system events that have tight real-time constraints and interfacing with systems external to the SoC. The PRU is both very small and very efficient at handling such tasks.

The major attributes of the PRU are as follows.

Attribute	Value
IO Architecture	Load / Store
Data Flow Architecture	Register to Register
Core Level Bus Architecture Type Instruction I/F Memory I/F 0 Memory I/F 1	 4-Bus Harvard (1 Instruction, 3 Data) 32-Bit 32-Bit 32-Bit
Execution Model Issue Type Pipelining Ordering ALU Type	 Scalar None (Purposefully) In Order Unsigned Integer

Accessibility to Internal PRU Structures	Provides 32-bit slave with three regions: • Instruction RAM • Control / Status registers • Debug access to internal registers (R0-R31) and constant table

Copyright © 2011, Texas Instruments Incorporated

The processor is based on a four-bus architecture which allows instructions to be fetched and executed concurrently with data transfers. In addition, an input is provided in order to allow external status information to be reflected in the internal processor status register. Figure 4-5 shows a block diagram of the processing element and the associated instruction RAM/ROM that contains the code that is to be executed.

4.5.2 Functional Description

This section describes the supported functionality of the PRU by describing the constant table, module interface and enhanced GPIOs, multiplier and optional accumulator, and scratch pad.

4.5.2.1 Constant Table

The PRU Constants Table is a structure connected to a dedicated interface on the PRU core within the PRU that is used to provide the base address for the Load Burst Constant + Offset (LBCO) and Store Burst Constant + Offset (SBCO). The PRU constants table is provided in order to maximize the usage of the PRU register file for embedded processing applications by moving many of the commonly used constant or deterministically calculated base addresses from the internal register file to an external table. Since this table is accessed using a dedicated interface, no performance difference is realized between the LBCO and LBBO or SBCO and SBBO instructions.

Table 4-9. PRU0/1 Constant Table

Entry No.	Region Pointed To	Value [31:0]
0	PRU0/1 Local INTC	0x0002_0000

Copyright © 2011, Texas Instruments Incorporated

NOTE: Constants not in this table can be created 'on the fly' by two consecutive LDI #16 instructions. These constants are just ones that are expected to be commonly used, enough so to be hard-coded in the PRU constants table.

Constants entries 24–31 are not fully hardcoded. They contain a programmable bit field (e.g., c24_blk_index[3:0]) that is programmable through the PRU control register space.

4.5.2.2 PRU Module Interface

The PRU module interface consists of the PRU internal registers 30 and 31 (R30 and R31). The register R31 serves as an interface with the dedicated PRU general purpose input (GPI) pins and INTC. Reading R31 returns status information from the GPI pins and INTC via the PRU Real Time Status Interface. Writing to R31generates PRU system events via the PRU Event Interface. The register R30 serves as an interface with the dedicated PRU general purpose output (GPO) pins.

4.5.2.2.1 Real-Time Status Interface Mapping (R31): Interrupt Events Input

The PRU Real Time Status Interface directly feeds information into register 31 (R31) of the PRU's internal register file. The firmware on the PRU uses the status information to make decisions during execution. The status interface is comprised of signals from different modules inside of the PRUSS which require some level of interaction with the PRU. More details on the Host interrupts imported into bit 30 and 31 of register R31 of both the PRUs is provided in the PRUSS Interrupt Controller (INTC) section.

Table 4-10. Real-Time Status Interface Mapping (R31) Field Descriptions

Bit	Field	Value	Description
31	pru_intr_in[1]		PRU Interrupt 1 from local INTC
30	pru_intr_in[0]		PRU Interrupt 0 from local INTC
29-0	pru<n>_r31_status[29:0]		Status inputs from primary input via Enhanced GPI port

4.5.2.2.2 Event Interface Mapping (R31): PRU System Events

This PRU Event Interface directly feeds pulsed event information out of the PRU's internal ALU. These events are exported out of the PRUSS and need to be connected to the system interrupt controller at the SoC level. The event interface can be used by the firmware to create software interrupts from the PRU to the Host processor.

Table 4-11. Event Interface Mapping (R31) Field Descriptions

Bit	Field	Value	Description
31-6	Reserved		
5	pru<n>_r31_vec_valid		Valid strobe for vector output
4	Reserved		
3-0	pru<n>_r31_vec[3:0]		Vector output

Writing a '1' to pru<n>_r31_vec_valid (R31 bit 5) simultaneously with a channel number from 0 to 16 written to pru<n>_r31_vec[3:0] (R31 bits 3:0) creates a pulse on the output of the appropriate demultiplexer output. For example, writing '100000' will generate a pulse on demux channel 0, writing '100001' will generate a pulse on demux channel 1, and so on to where writing '101111' will generate a pulse on demux channel 15 and writing '0xxxxx' will not generate any pulse on the demux output. The demultiplexed values from both PRU are ORed together. The composite demultiplexed output channels 0–15 are connected to system interrupts 16–31, respectively.

Copyright © 2011, Texas Instruments Incorporated

This allows the PRU to assert one of the system interrupts 16-31 by writing to its own R31 register. The system interrupt is used to either post a completion event to one of the host CPUs (ARM) or to signal the other PRU. The host to be signaled is determined by the system interrupt to interrupt channel mapping (programmable). The 16 events are named as pr<0/1>_pru_mst_intr<15:0>_intr_req. See the PRUSS Interrupt Controller (INTC) for more details.

4.5.2.2.3 General-Purpose Inputs (R31): Enhanced PRU GP Module

The PRUSS implements an enhanced General Purpose Input Output (GPIO) module that supports direct connection, 16-bit parallel capture, 28-bit serial shift, and MII_RT modes for general purpose inputs. Register R31 serves as an interface with the general purpose inputs. Table 4-12 describes the four input modes in detail.

Table 4-12. PRU 31 (GPI) Modes

Mode	Function	Configuration
Direct connection	PRU<n>_DATAIN (pru<n>_r31_status [16:0]) feeds directly into the PRU	Default state
16-bit parallel capture	PRU<n>_DATAIN (pru<n>_r31_status [15:0]) is captured by posedge of PRU<n>_CLOCK (pru<n>_r31_status [16]) or the negedge of PRU<n>_CLOCK	Enabled by CFG
28-bit shift	PRU<n>_DATAIN (pru<n>_r31_status [0]) is sampled and shifted into a 28-bit shift register. Shift Counter (Cnt_16) feature uses pru<n>_r31_status [28]. Start Bit detection (SB) feature uses pru<n>_r31_status [29].	Enabled by CFG Start Bit (SB) is cleared by CFG Cnt_16 is cleared by CFG
MII_RT	mii_rt_r31_status [29:0] internally driven by the MII_RT module	Enabled by CFG

Only one GPI mode is active at a time. Each mode uses the same R31 signals and internal register bits for different purposes. A summary of the naming convention for each mode and corresponding signal names and aliases are found in the following table

Table 4-13. GPI Mode Descriptions

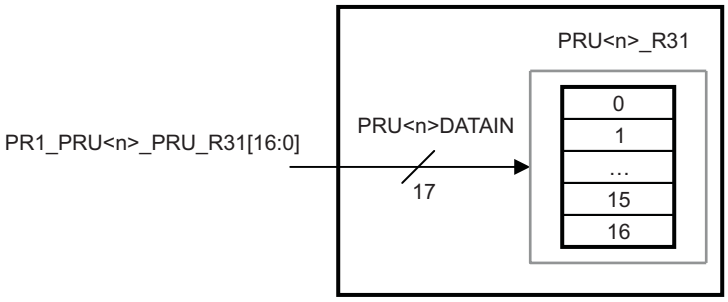
Function	Alias	Internal Signal Name
Direct Mode		
Data input	PRU<n>_DATAIN	pru<n>_r31_status[16:0]
Parallel Capture Mode		
Data input	PRU<n>_DATAIN	pru<n>_r31_status[15:0]
Clock	PRU<n>_CLOCK	pru<n>_r31_status[16]
Shift Mode		
Data input	PRU<n>_DATAIN	pru<n>_r31_status[0]
Shift counter	PRU<n>_CNT_16	pru<n>_r31_status[28]
Start bit detection	PRU<n>_GPI_SB	pru<n>_r31_status[29]

4.5.2.2.3.1 Direct Connection

The pru<n>_r31_status [16:0] (PRU<n>_DATAIN) signals are mapped out of the PRUSS and are brought out as general purpose input pins. Each PRU of the PRUSS has a separate mapping to pins so that there are 34 total general purpose inputs to the PRUSS. See the device's system reference guide or datasheet for device specific pin mapping.

Copyright © 2011, Texas Instruments Incorporated

Figure 4-6. PRU R31 (GPI) Direct Connection Mode Block Diagram

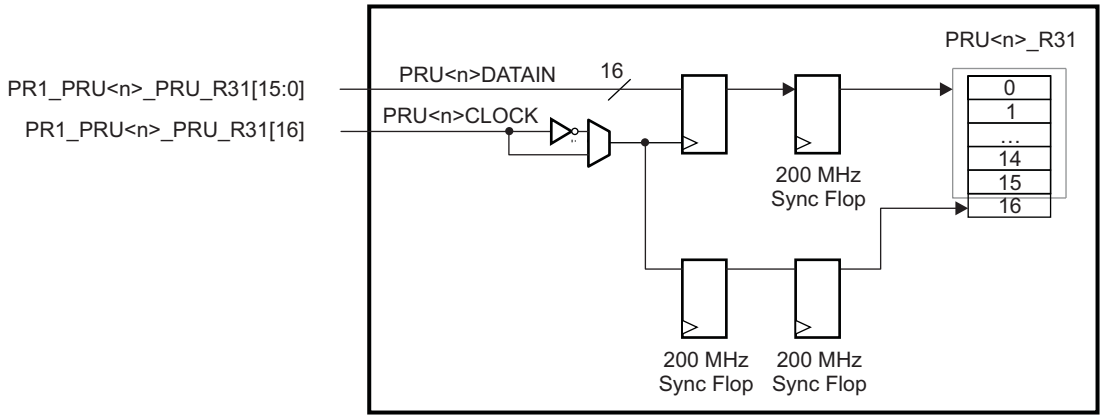


4.5.2.2.3.2 16-Bit Parallel Capture

The pru<n>_r31_status [16:0] are mapped out of the PRUSS and are brought out as general-purpose input pins. The pru<n>_r31_status [16] (PRU<n>_CLOCK) is designated for an external strobe clock and is used to capture pru<n>_r31_status [15:0] (PRU<n>_DATAIN). The PRU<n>_DATAIN can be captured either by the positive or the negative edge of PRU<n>_CLOCK, programmable through the PRUSS CFG register space.

If the clocking is configured through the PRUSS CFG register to be positive, then it will equal PRU<n>_CLOCK. However, if the clocking is configured to be negative, then it will equal PRU<n>_CLOCK inverted.

Figure 4-7. PRU R31 (GPI) 16-Bit Parallel Capture Mode Block Diagram



4.5.2.2.3.3 28-Bit Shift

The pru<n>_r31_status [0] (PRU<n>_DATAIN) is sampled and shifted into a 28-bit shift register on an internal clock pulse. The register fills in LSB order (from bit 0 to 27) and then overflows into a bit bucket. The 28-bit register can be cleared in software through the PRUSS CFG register space.

The shift rate is controlled by the effective divisor of two cascaded dividers applied to the 200-MHz clock. These cascaded dividers can each be configured through the PRUSS CFG register space to a value of {1, 1.5, …, 16}. Table 4-14 shows sample effective clock values and the divisor values that can be used to generate these clocks.

Table 4-14. Effective Clock Values

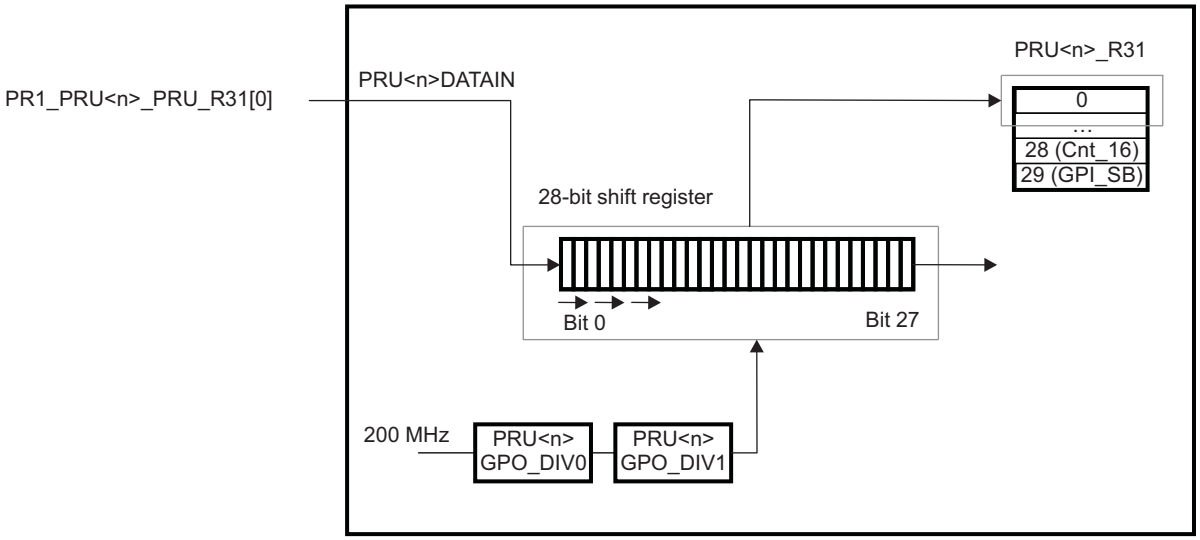
Generated clock	PRU<n>_GPI_DIV0	PRU<n>_GPI_DIV1
8-MHz	12.5 (0x15)	2 (0x02)
10-MHz	10 (0x10)	2 (0x02)
16-MHz	16 (0x1e)	1 (0x00)
20-MHz	10 (0x10)	1 (0x00)

Copyright © 2011, Texas Instruments Incorporated

The 28-bit shift mode also supports the following features:

- Start Bit (PRU<n>_GPI_SB or pru<n>_r31_status [29]) is set when the first 1 is captured on PRUn_DATAIN. PRUn_GPI_SB is cleared in software through the PRUSS CFG register space.
- Cnt_16 (PRU<n>_CNT_16 or pru<n>_r31_status [28]) is set on every 16 shift clock samples after the Start Bit has been received. PRU<n>_CNT_16 is self clearing and is connected to the PRUSS INTC. See the PRUSS Interrupt Controller (INTC) section for more details.

Figure 4-8. PRU R31 (GPI) 28-Bit Shift Mode



4.5.2.2.3.4 General-Purpose Outputs (R30): Enhanced PRU GP Module

The PRUSS implements an enhanced General Purpose Input Output (GPIO) module that supports direct connection and shift out modes for general purpose outputs. Table 4-15 describes these modes in detail.

Table 4-15. PRU R30 (GPO) Output Mode

Mode	Function	Configuration
Direct connection	PRU<n>_DATAOUT (pru<n>_r30 [15:0]) feeds directly out of the PRU	Default state
Shift out	PRU<n>_DATAOUT (pru<n>r30 [0]) is shifted out on every rising edge of PRU<n>_CLOCK (pru<n>r30 [1])	Enabled by CFG

Only one GPO mode is active at a time. Each mode uses the same R30 signals and internal register bits for different purposes. A summary of the naming convention for each mode and corresponding signal names and aliases are found in the following table.

Table 4-16. GPO Mode Descriptions

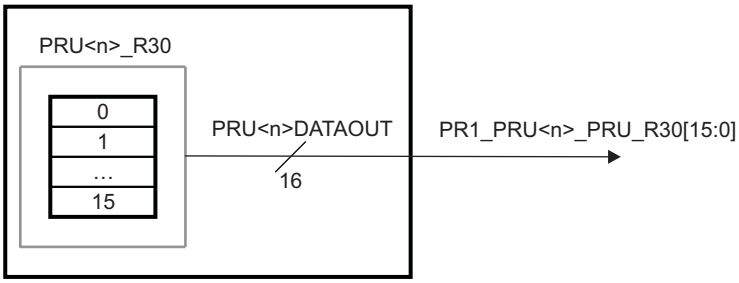
Function	Alias	Internal Signal Name
Direct Mode		
Data output	PRU<n>_DATAOUT	pru<n>_r30 [15:0]
Shift Mode		
Data output	PRU<n>_DATAOUT	pru<n>_r30 [0]
Clock	PRU<n>_CLOCK	pru<n>_r30 [1]
Load gpo_sh0	PRU<n>_LOAD_GPO_SH0	pru<n>_r30 [29]
Load gpo_sh1	PRU<n>_LOAD_GPO_SH1	pru<n>_r30 [30]
Enable shift	PRU<n>_ENABLE_SHIFT	pru<n>_r30 [31]

Copyright © 2011, Texas Instruments Incorporated

4.5.2.2.3.4.1 Direct Connction

The pru<n>_r30 [15:0] (PRU<n>_DATAOUT) bits are exported out of the PRUSS and are brought out as general purpose output pins. Each PRU of the PRUSS has a separate mapping to pins, so that there are 32 total general-purpose outputs from the PRUSS. See the device's system reference guide or datasheet for device-specific pin mapping.

Figure 4-9. PRU R30 (GPO) Direct Connection Mode Block Diagram



4.5.2.2.3.4.2 Shift Out

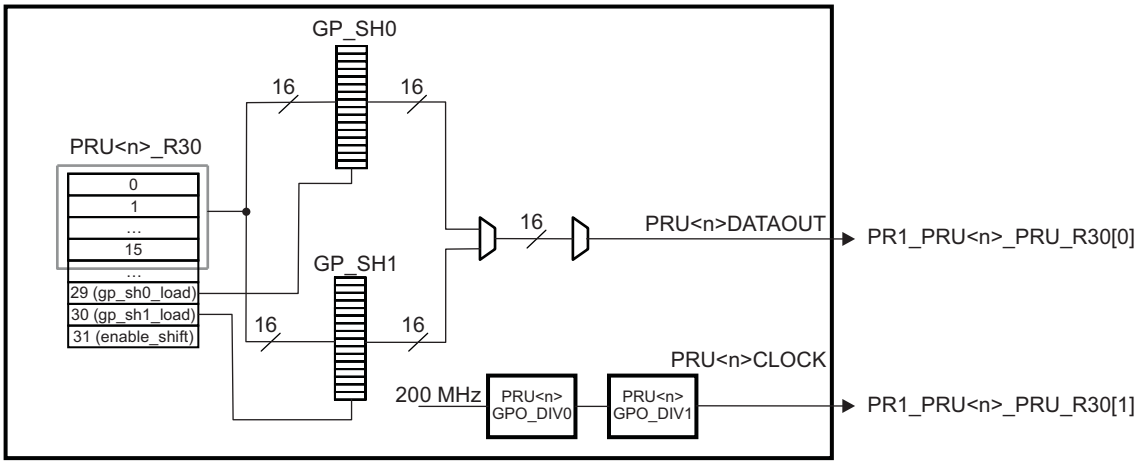
In shift out mode, data is shifted out of pru<n>_r30[0] (PRU<n>_DATAOUT) on every rising edge of pru<n>_r30[1] (PRU<n>_CLOCK). The shift rate is controlled by the effective divisor of two cascaded dividers applied to the 200-MHz clock. These cascaded dividers can each be configured through the PRUSS CFG register space to a value of {1, 1.5, …, 16}. Table 4-17 shows sample effective clock values and the divisor values that can be used to generate these clocks.

Table 4-17. Effective Clock Values

Generated Clock	PRU<n>_GPO_DIV0	PRU<n>_GPO_DIV1
8 MHz	12.5 (0x15)	2 (0x02)
10 MHz	10 (0x10)	2 (0x02)
16 MHz	16 (0x1e)	1 (0x00)
20 MHz	10 (0x10)	1 (0x00)

Shift out mode uses two 16-bit shadow registers (gpo_sh0 and gpo_sh1) to support ping-pong buffers. Each shadow register has independent load controls programmable through pru<n>_r30[29:30] (PRU<n>_LOAD_GPO_SH [0:1]). The data shift will start from gpo_sh0 when pru<n>_r30[31] (PRU<n>_ENABLE_SHIFT) is set. Note that if no new data is loaded into gpo_shn<n> after shift operation, the shift operation will continue looping and shifting out the pre-loaded data. The shift operation will stop and reset when PRU<n>_ENABLE_SHIFT is cleared.

Figure 4-10. PRU R30 (GPO) Shift Out Mode Block Diagram



Copyright © 2011, Texas Instruments Incorporated

Follow these steps to use the GPO shift out mode:

Initialization:

Load 16-bits of data into gpo_sh0

Set R30[29] = 1 (PRU<n>_LOAD_GPO_SH0)

Load data in R30[15:0]

Clear R30[29] to turn off load controller

Load 16-bits of data into gpo_sh1

Set R30[30] = 1 (PRU<n>_LOAD_GPO_SH1)

Load data in R30[15:0]

Clear R30[30] to turn off load controller

Start shift operation

Set R30[31] = 1 (PRU<n>_ENABLE_SHIFT)

Shift Loop:

Monitor when a shadow register has finished shifting out data and can be loaded with new data

Poll PRU<n>_GPI_SH_SEL bit of the GPCFG<n> register

Load new 16-bits of data into gpo_sh0 if PRU<n>_GPI_SH_SEL = 1

Load new 16-bits of data into gpo_sh1 if PRU<n>_GPI_SH_SEL = 0

If more data to be shifted out, loop to Shift Loop

If no more data, exit loop

Exit:

End shift operation

Clear R30[31] to turn off shift operation

NOTE: Until the shift operation is disabled, the shift loop will continue looping and shifting out the pre-loaded data if no new data has been loaded into gpo_sh<n>.

4.5.2.3 Multiplier With Optional Accumulation

Each PRU core has a designated multiplier with optional accumulation (MAC). The MAC has two modes of operation: Multiply Only or Multiply and Accumulate. The MAC is directly connected with the PRU internal registers R25–R29 and uses the broadside load/store PRU interface and XFR instructions to both control the mode of the MAC and import the multiplication results into the PRU.

4.5.2.3.1 Features

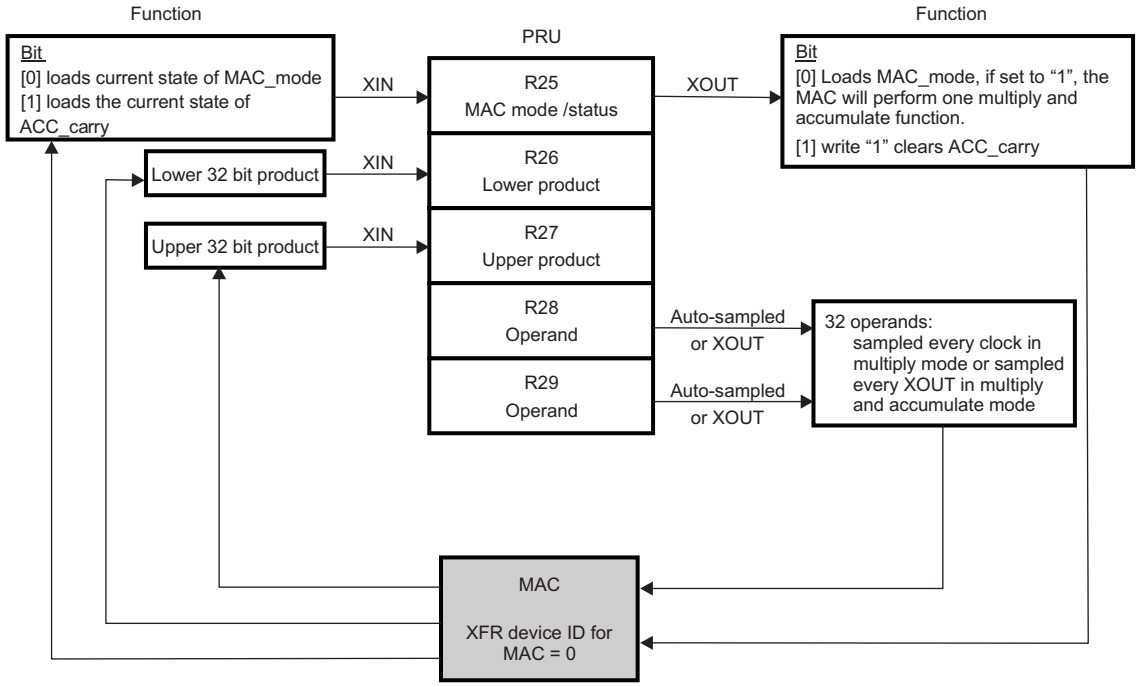
- Configurable Multiply Only and Multiply and Accumulate functionality via PRU register R25
- 32-bit operands with direct connection to PRU registers R29 and R28
- 64-bit result (with carry flag) with direct connection to PRU registers R26 and R27
- PRU broadside interface and XFR instructions (XIN, XOUT) allow for importing multiplication results and initiating accumulate function

4.5.2.3.2 PRU and MAC Interface

The MAC directly connects with the PRU internal registers R25–R29 through use of the PRU broadside interface and XFR instructions. Figure 4-11 shows the functionality of each register.

Copyright © 2011, Texas Instruments Incorporated

Figure 4-11. Integration of the PRU and MAC



The XFR instructions (XIN and XOUT) are used to load/store register contents between the PRU core and the MAC. These instructions define the start, size, direction of the operation, and device ID. The device ID number corresponding to the MAC is 0.

The PRU register R25 is mapped to the MAC_CTRL_STATUS register (Table 4-18). The MAC's current status (MAC_mode and ACC_carry states) is loaded into R25 using the XIN command on R25. The PRU sets the MAC's mode and clears the ACC_carry using the XOUT command on R25.

Table 4-18. MAC_CTRL_STATUS Register (R25) Field Descriptions

Bit	Field	Value	Description
7-2	Reserved		Reserved
1	ACC_carry		Write 1 to clear
		0	64-bit accumulator carry has not occurred
		1	64-bit accumulator carry occurred
0	MAC_mode	0	Accumulation mode disabled and accumulator is cleared
		1	Accumulation mode enabled

The two 32-bit operands for the multiplication are loaded into R28 and R29. These registers have a direction connection with the MAC. Therefore, XOUT is not required to load the MAC. In multiply mode, the MAC samples these registers every clock cycle. In multiply and accumulate mode, the MAC samples these registers every XOUT R25[7:0] transaction when MAC_mode = 1.

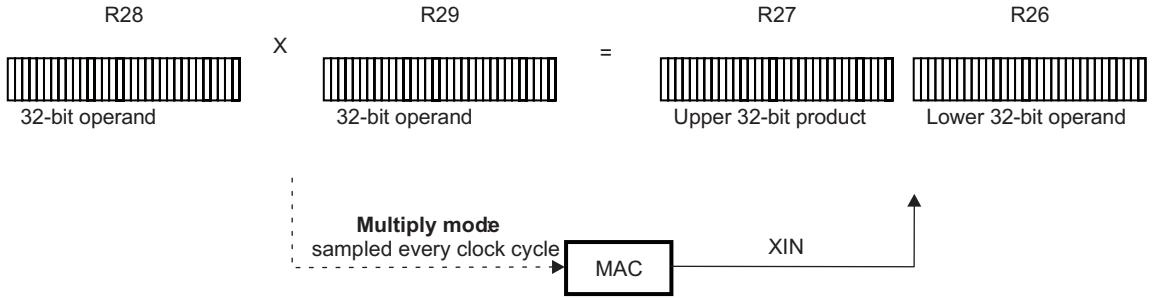
The product from the MAC is linked to R26 (lower 32 bits) and R27 (upper 32 bits). The product is loaded into register R26 and R27 using XIN.

4.5.2.3.2.1 Multiply-Only Mode (Default State), MAC_mode = 0

On every clock cycle, the MAC multiplies the contents of R28 and R29.

Copyright © 2011, Texas Instruments Incorporated

Figure 4-12. Multiply-Only Mode Functional Diagram



The following steps are performed by the PRU firmware for multiply-only mode:

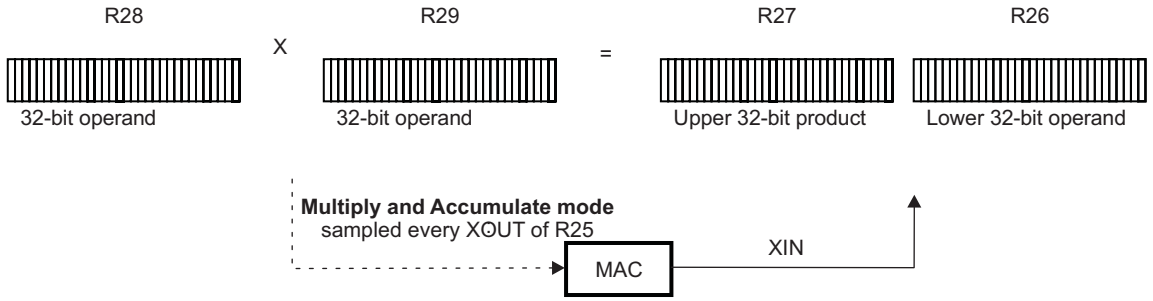
1. Enable multiply only MAC_mode.
   - Clear R25[0] for multiply only mode.
   - Store MAC_mode to MAC using XOUT instruction on R25. For example: XOUT 0, R25, 1.
2. Load operands into R29 and R28.
3. Load product into PRU using XIN instruction on R27, R26.

Repeat steps 2 and 3 for each new operand.

4.5.2.3.2.2 Multiply and Accumulate Mode, MAC_mode = 1

On every XOUT R25_reg[7:0] transaction, the MAC multiplies the contents of R28 and R29, adds the product to its accumulated result, and sets ACC_carry if an accumulation overflow occurs.

Figure 4-13. Multiply and Accumulate Mode Functional Diagram



The following steps are performed by the PRU firmware for multiply and accumulate mode:

1. Enable multiply and accumulate MAC_mode.
   - Set R25[1:0] = 1 for accumulate mode.
   - Store MAC_mode to MAC using XOUT instruction on R25. For example: XOUT 0, R25, 1.
2. Clear accumulator and carry flag.
   - Set R25[1:0] = 3 to clear accumulator.
   - Store accumlator to MAC using XOUT instruction on R25. For example: XOUT 0, R25, 1.
3. Load operands into R29 and R28.
4. Multiply and accumulate, XOUT R25_reg[1:0] = 1

   Repeat step 4 for each multiply and accumulate using same operands.

   Repeat step 3 and 4 for each multiply and accumulate for new operands.
5. Load the accumulated product into R27_reg, R26_reg and the ACC_carry status into R25_reg using the XIN instruction.

Note: Steps one and two are required to set the accumulator mode and clear the accumulator and carry flag.

Copyright © 2011, Texas Instruments Incorporated

4.5.2.4 PRU0/1 Scratch Pad

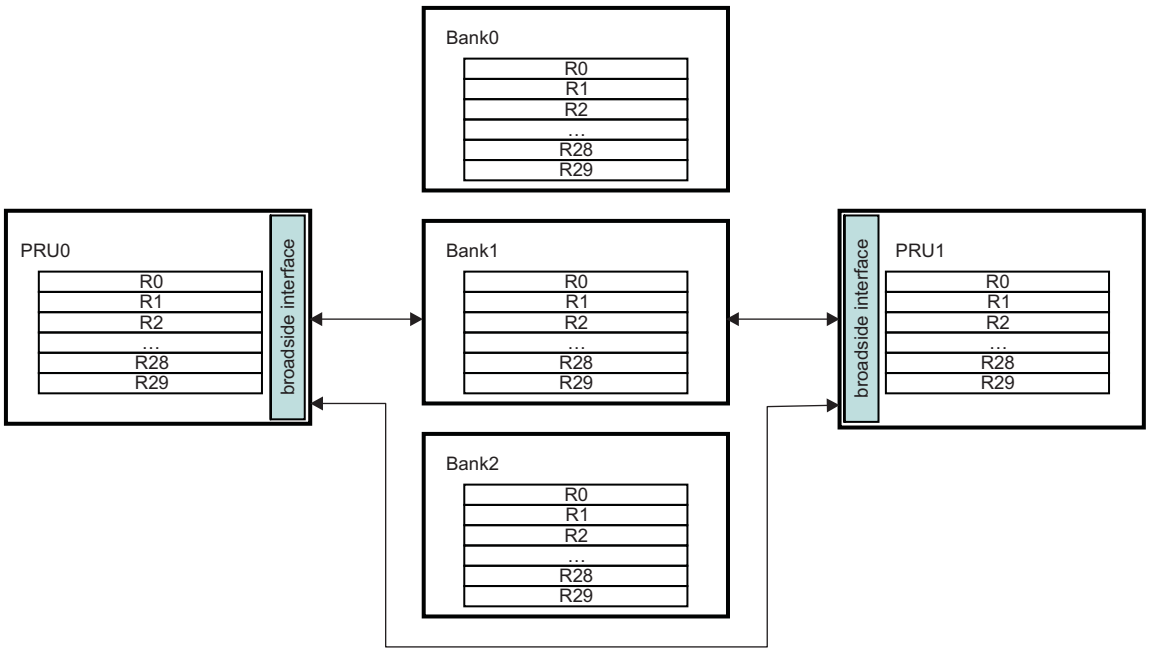
The PRUSS supports a scratch pad with three independent banks accessible by the PRU cores. The PRU cores interact with the scratch pad through broadside load/store PRU interface and XFR instructions. The scratch pad can be used as a temporary place holder for the register contents of the PRU cores. Direct connection between the PRU cores is also supported for transferring register contents directly between the cores.

4.5.2.4.1 Features

The PRUSS scratch pad supports the following features:

- Three scratch pad banks of 30, 32-bit registers (R29:0)
- Flexible load/store options
  - User-defined start byte and length of the transfer
  - Length of transfer ranges from one byte of a register to the entire register content (R29 to R0)
  - Simultaneous transactions supported between PRU0 ↔ Bank<n> and PRU1 ↔ Bank<m>
  - Direct connection of PRU0 → PRU1 or PRU1 → PRU0 for all registers R29–R0
- XFR instruction operate in one clock cycle
- Optional XIN/XOUT shift functionality allows remapping of registers (R<n> → R<m>) during load/store operation

Figure 4-14. Integration of PRU and Scratch Pad



4.5.2.4.2 Implementations and Operations

XFR instructions are used to load/store register contents between the PRU cores and the scratch pad banks. These instructions define the start, size, direction of the operation, and device ID. The device ID corresponds to the external source or destination (either a scratch pad bank or the other PRU core). The device ID numbers are shown in Table 4-19. Note the direct connect mode (device ID 14) can be used to synchronize the PRU cores.

Copyright © 2011, Texas Instruments Incorporated

Table 4-19. Scratch Pad XFR ID

Device ID	Function
10	Selects Bank0
11	Selects Bank1
12	Selects Bank2
13	Reserved
14	Selects other PRU core (Direct connect mode)

A collision occurs when two XOUT commands simultaneously access the same asset or device ID. Table 4-20 shows the priority assigned to each operation when a collision occurs. In direct connect mode (device ID 14), any PRU transaction will be terminated if the stall is greater than 1024 cycles. This will generate the event pr<1/0>_xfr_timeout that is connected to INTC.

Table 4-20. Scratch Pad XFR Collision Conditions

Operation	Collision Handling
PRU<n> XOUT (→) bank[j]	If both PRU cores access the same bank simultaneously, PRU0 is given priority. PRU1 will temporarily stall until the PRU0 operation completes.
PRU<n> XOUT (→) PRU<m>	If PRU<n> executes XOUT before PRU<m> executes XIN, then PRU<n> will stall until either PRU<m> executes XIN or the stall is greater than 1024 cycles.
PRU<n> XIN (←) PRU<m>	If PRU<n> executes XIN before PRU<m> executes XOUT, then PRU<n> will stall until either PRU<m> executes XIN or the stall is greater than 1024 cycles.

4.5.2.4.2.1 Optional XIN/XOUT Shift

The optional XIN/XOUT shift functionality allows register contents to be remapped or shifted within the destination's register space. For example, the contents of PRU0 R6-R8 could be remapped to Bank1 R10-12. The XIN/XOUT shift feature is not supported for direct connect mode, only for transfers between a PRU core and scratch pad bank.

The shift feature is enabled or disabled through the SPP register of the PRUSS CFG register space. When enabled, pru<n> r18:29 will correspond to bank<n> r22:r3. Note that scratch pad banks do not have registers R30 or R31.

4.5.2.4.2.2 Example Scratch Pad Operations

The following PRU firmware examples demonstrate the shift functionality. Note these assume the SHIFT_EN bit of the SPP register of the PRUSS CFG register space has been set.

XOUT Shift By 4 Registers

```
MOV R0.b0, 4
XOUT 10, R4, 16 // Store R4:R7 to R8:R11 in bank0
```

XOUT Shift By 9 Registers, With Wrap Around

```
MOV R0.b0, 9
XOUT 11, R25, 20 // Store R25:R29 to R4:R9 in bank1
```

XIN Shift By 10 Registers

```
MOV R0.b0, 10
XIN 12, R4, 12 // Load R14:R16 from bank2 to R4:R6
```

4.5.3 Basic Programming Model

4.5.3.1 PASM — PRU Assembler Overview

PASM is a command-line-driven assembler for the programmable real-time execution unit (PRU) of the programmable real-time unit subsystem (PRUSS). It is designed to build single executable images using a flexible source code syntax and a variety of output options. PASM is available for Windows and Linux.

4.5.3.1.1 Calling Syntax

The command line syntax to PASM is:

```
pasm_2 -PRUv2[bcmldz] SourceFile [OutFileBasename] [-Dname=value] [-CArrayName]
```

Note that only the source file SourceFile is required on the command line. The assembler will default to output option "-c" which generates a C array containing the binary opcode data. The majority of the option flags select a variety of output formats.

The output file OutFileBasename is a base name only. It defaults to the same name as the source file (for example "myprog.p" would have a default base name of "myprog"). Standard filename extensions are applied to the base name to create the final output filename(s), depending on the output option(s) selected.

When specifying PASM options, options can be specified individually or as a group. For example, either of the two invocations below is valid:

```
pasm_2 -PRUv2 -cdl myprog.p
pasm_2 -PRUv2 -c -d -l myprog.p
```

Filenames and options can also be mixed, for example:

```
pasm_2 -PRUv2 myprog.p -cdl
pasm_2 -PRUv2 -cd myprog.p -DMYVAL=1 -l
```

4.5.3.1.1.1 Output Formats

All program images start at Programmable Real-Time Unit (PRU) address 0. For example, if a program has an internal origin of 8, the first eight 32 bit words of the program image output will be zero.

The following output options are supported. The output file name shown in the table is generated assuming a base name of “myprog”:

Command Line Option	Output Format	Output Filename
-b	Little endian binary file	myprog.bin
-c	C include file containing unsigned long array called PRUcode[][(1)]	myprog_bin.h
-m	Image file containing one 32 bit hex opcode per line	myprog.img
-L	Listing file containing original source code and generated opcodes.	myprog.txt
-l	Listing file containing post-processed code and generated opcodes	myprog.lst
-d	Debugger output file (opcodes with source and label info)	myprog.dbg

(1) The name “PRUcode[]” can be redefined using the –C option.

Copyright © 2011, Texas Instruments Incorporated

4.5.3.1.1.2 Additional Options

PASM supports some additional command line options that are not associated with output file format:

Command Line Option	Function
-PRUv2	Version number. PRUv2 for PRUSSv2.
-C	Rename the code array declared when using the -c option
-D	Constant definition
-z	Enable PASM assembler debug output

4.5.3.1.1.2.1 Rename the Code Array for the -c Option

By default, the –c option will create an output file with a name ending in "_bin.h". Inside this created include file, the output code is defined as a C array of 32 bit values. The default name of the array is "PRUcode[]". The –C option allows the user to redefine this name to something more appropriate. For example the following command line will create an output file named "myprog_bin.h", and the C array inside the created file will be called "MyProg_Release_003a[]".

```
pasm_2 -PRUv2 -c myprog.p -CMyProg_Release_003a
```

4.5.3.1.1.2.2 Constant Definitions

When the "-D" option is specified, the remaining command line argument is interpreted as a constant assignment. For example, to add an assignment "1" to the constant "MYVAL", any of the following is valid:

```
pasm_2 -PRUv2 -cdl myprog.p -DMYVAL=1
pasm_2 -PRUv2 -c -d -l -DMYVAL=1 myprog.p
pasm_2 -PRUv2 myprog.p -cdlDMYVAL=1
```

Since the default value assigned to a constant is "1", the following is also equivalent:

```
pasm_2 -PRUv2 -c -d -l -DMYVAL myprog.p
```

Note that constants defined on the command line do not override constants defined in the source code.

4.5.3.2 PASM Source File Syntax

PASM is a non-linking two pass assembler. It assembles programs as a single monolithic image and directly generates executable code. As there is no linking stage in a PASM build, there are no section or segment directives, nor memory maps or command files.

In PASM, there are four basic assembly operators. These include dot "." commands, hash "#" commands, labels, and instructions (mnemonics). The user may supply comments that are invisible to the assembler.

4.5.3.2.1 Dot Commands

Dot commands are used to control the assembler, for example ".origin" and ".proc". They can also be used to declare complex data types as in the ".struct" directive.

4.5.3.2.1.1 Syntax

The rules for a dot command are as follows:

- Must be the only assembly type on the line
- Can be followed by a comment
- Does not need to start in column 0

4.5.3.2.1.2 Origin (.origin) Command

The origin command is used to specify a code offset in the PRU source file. Typically a single origin statement is specified before any instructions, but multiple origin commands can be specified in order to insert space into the code map.

Example:

Copyright © 2011, Texas Instruments Incorporated

```
.origin    8       // Start the next instruction at code offset 8
```

4.5.3.2.1.3 Entry Point (.entrypoint) Command

The entry point command is used to specify the code entry point to the debugger, and stores the information in the debug output file (*.dbg). It has no affect on any other output file type.

By default PASM will set the entry point to the first instruction generated by the assembly.

Examples:

```
.entrypoint 0          // Set code entrypoint to address 0
.entrypoint Start    // Set code entrypoint to the code label "Start"
```

4.5.3.2.1.4 Set Call/Return Register (.setcallreg) Command

This command sets the call/return register that is used in the CALL and RET pseudo op instructions. If this command is not specified, a default register of R30.w0 is used. This command must appear in the source code prior to any program instructions, and it must specify a 16-bit register field.

Example:

```
.setcallreg  r15.w2  // Use R15.W2 in the CALL/RET pseudo ops
```

4.5.3.2.1.5 Start Macro Definition (.macro)

The .macro command is used to begin the definition of a macro. In the assembler, a macro can only be used in place of an opcode. There is always a single parameter to the command, being the name of the macro. Each macro section must start with a ".macro" and end with an ".endm".

See Section 4.5.3.3.1 for more details on using macros.

Example:

```
.macro  mov32              // Define macro "mov32"
```

4.5.3.2.1.6 Specific Macro Parameter(s) (.mparam)

The .mparam command is used to add one or more parameters to a macro. The form of the command is:

```
.mparam   param1 [= default_value] [, param2 [= default_value] ]
```

When a parameter is given a default value, it is considered an optional parameter. Any optional parameters must be the last parameters specified in the parameter list. It is acceptable to supply both required and optional parameters on the same .mparam line.

See Section 4.5.3.3.1 for more details on using macros.

Example:

```
.mparam    dst, src    // Define 2 required parameters, "dst" and "src"
.mparam    temp = r0   // Define an optional parameter "temp" that
                          // defaults to the value 'r0'.
```

4.5.3.2.1.7 End Macro Definition (.endm)

The .endm command is used to complete the definition of a macro. It is required at the end of any macro specification. There are no parameters.

See Section 4.5.3.3.1 for more details on using macros.

Example:

```
.endm                  // Completed defining macro
```

Copyright © 2011, Texas Instruments Incorporated

4.5.3.2.1.8 Structure (.struct) Command

The structure command is used to open a declaration to a new structure in PASM. PASM uses structures to generate standard equates, and allow the user to perform register allocation to private structure instances.

See Section 4.5.3.3.2 for more details on using scope and structures.

Example:

```
.struct myStruct        // Declare a structure template called "myStruct"
```

4.5.3.2.1.9 End Structure (.ends) Command

The end structure command is used to close a structure declaration. PASM uses structures to generate standard equates, and allow the user to perform register allocation to private structure instances.

See Section 4.5.3.3.2 for more details on using scope and structures.

Example:

```
.ends
```

4.5.3.2.1.10 Field Directives (.u8, .u16, .u32)

Field directives are used within an open structure declaration to define fields within the structure.

See Section 4.5.3.3.2 for more details on using scope and structures.

Example:

```
.struct MyStruct
    .u32    MyInt                   // 32-bit field
    .u16    MyShort                   // 16-bit field
    .u8    MyByte1                   // 8-bit field
    .u8    MyByte2                   // 8-bit field
.ends
```

4.5.3.2.1.11 Assignment Directive (.assign)

The assignment directive is used to map a defined structure onto the PRU register file. An assign statement can begin on any register boundary.

The programmer may declare the full assignment span manually (both starting and ending register), or leave the ending register blank. When the programmer declares a full register span, PASM will generate an error when the specified span is incorrect. This allows the programmer to formally map structures to specific register spans, reducing the chance that register assignments will accidentally overlap.

Some structures will also require specific alignments due to how their fields are arranged within the structure. PASM will generate an error if the structure alignment requirements can not be met with the specified starting register.

See Section 4.5.3.3.2 for more details on using scope and structures.

Example:

```
.assign MyStruct, R4, R5, MyName1  // Make sure this uses R4 thru R5
.assign MyStruct, R6,  *, MyName2  // Don't need to validate the range
```

4.5.3.2.1.12 Enter New Variable Scope (.enter)

The .enter command is used to create and enter a new variable scope. There is a single parameter to the command that specifies the name of the scope. Any structures that are assigned inside a named scope can only be accessed when the scope is open. Use of variable scopes is optional.

See Section 4.5.3.3.2 for more details on using scope and structures.

Example:

```
.enter  Scope1      // Create and enter scope named "Scope1"
```

Copyright © 2011, Texas Instruments Incorporated

4.5.3.2.1.13 Leave a Variable Scope (.leave)

The .leave command is used to leave a specific variable scope. There is a single parameter to the command that specifies the name of the scope to leave. Scopes do not need to be entered or left in any particular order, but a natural ordering can be enforced by the programmer.

See Section 4.5.3.3.2 for more details on using scope and structures.

Example:

```
.enter Scope1                   // Create and enter scope named "Scope1"
    .enter Scope2                   // Create and enter scope named "Scope2"
    .leave Scope2                   // Leave scope named "Scope2"
.leave Scope1                   // Leave scope named "Scope1"
```

4.5.3.2.1.14 Referencing an Existing Variable Scope (.using)

The .using command is used to enter a specific variable scope that has been previously created and left. There is a single parameter to the command that specifies the name of the scope to enter. The .leave command is then used to leave the scope after being entered with .using.

See Section 4.5.3.3.2 for more details on using scope and structures.

Example:

```
.using Scope1                   // Enter existing scope named "Scope1"
    .using Scope2                   // Enter existing scope named "Scope2"
    .leave Scope2                   // Leave scope named "Scope2"
.leave Scope1                   // Leave scope named "Scope1"
```

4.5.3.2.2 Hash Commands

Hash commands are used to control the assembler pre-processor. They are quite similar to their C counterparts.

4.5.3.2.2.1 Syntax

The rules for a hash command are as follows:

- Must be the only assembly type on the line
- Can be followed by a comment
- Does *not* need to start in column 0

4.5.3.2.2.2 Include (#include) Command

The #include command is used to include additional source files in the assembly process. When a “#include” is specified, the included file is immediately opened, parsed, and processed.

The calling syntax for #include can use quotes ‘” “’ or brackets “< >". Specifying quotes is functionally equivalent to specifying brackets. For example:

```
#include "localInclude.h"

#include "c:\include\myInclude.h"

#include <inc\myInclude.h>
```

As PASM uses a monolithic single source approach, the #include statement can be used to specify external source files. This allows a developer to break up a complicated application into several smaller source files.

For example, an application may consist of a master source file “myApp.p” which itself contains nothing but include commands for including sub source files. The contents of “myApp.p” may appear as follows:

```
#include "myInitialization.p"
#include "myMainLoop.p"
#include "mySubroutines.p"
```

Copyright © 2011, Texas Instruments Incorporated

The above lines would include each source file in turn, concatenating one after the other in the final code image. Each of these included source files may have additional include files of their own.

Including the same include file multiple times will not result in an error, however including files recursively will result in an error.

4.5.3.2.2.3 Define (#define) Command

The “#define” command is used to specify a simple text substitution. Any text defined in a #define is substituted for the defined name within the code.

For example, if the programmer writes:

```
#define BUFFER_ADDRESS    0x08001000
    ldi     r1.w0, BUFFER_ADDRESS & 0xFFFF
    ldi     r1.w2, BUFFER_ADDRESS >> 16
```

This would load 0x1000 into register r1.w0 and then 0x0800 into register r1.w2.

Equates are expanded recursively, so the value of the define does not need to be resolved until it is used. For example:

```
#define B A
#define A 1
        ldi     r1, B
```

The above will load “1” in register r1.

4.5.3.2.2.4 Undefine (#undef) Command

The “#undef” command is used to undefined a constant that was previously assigned via #define.

For example:

```
// Redefine our buffer address without generating an assmbler warning
#undef BUFFER_ADDRESS
#define BUFFER_ADDRESS    0x08001000
```

4.5.3.2.2.5 Error (#error) Command

The “#error” command is used to specify an error during assembly. For example, if the programmer wishes to verify the constant value MYMODE is defined, they can write:

```
#ifndef MYMODE
#error Mode not specified
#endif
```

The above will produce an error if the program is assembled and MYMODE is not defined.

4.5.3.2.2.6 Warning (#warn) Command

The “#warn” command is used to specify a warning during pass 1 of the assembly. For example, if the programmer wishes to verify the constant value MYMODE is defined, but still allow a default mode, they can write:

```
#ifndef MYMODE
#warn   Mode not specified - setting default
#define MYMODE DEFAULT_MODE
#endif
```

The above will produce an assembler warning if the program is assembled and MYMODE is not defined.

Copyright © 2011, Texas Instruments Incorporated

4.5.3.2.2.7 Notation (#note) Command

The “#note” command is used to specify a notation during pass 1 of the assembly. For example, if the programmer wishes to allow a default setting of the constant value MYMODE, but still notify the programmer what is happening, they can write:

```
#ifndef MYMODE
#note   Using default MYMODE
#define MYMODE DEFAULT_MODE
#endif
```

The above will produce an assembler notation if the program is assembled and MYMODE is not defined, but it is not counted as an error or a warning.

4.5.3.2.2.8 If Defined (#ifdef) Command

The “#ifdef” command is used to specify a block of conditional code based on whether the supplied constant is defined. Here, the code inside the #ifdef block will be assembled only if the constant is defined, regardless of its defined value. Every #ifdef must be followed by a #endif. For example:

```
#define MYVAL 1
#ifdef MYVAL
    // This code in this block will be assembled
#endif

#undef MYVAL
#ifdef MYVAL
    // This code in this block will NOT be assembled
#endif
```

4.5.3.2.2.9 If Not Defined (#ifndef) Command

The “#ifndef” command is used to specify a block of conditional code based on whether the supplied constant is defined. Here, the code inside the #ifndef block will be assembled only if the constant is not defined. Every #ifndef must be followed by a #endif. For example:

```
#define MYVAL 1
#ifndef MYVAL
    // This code in this block will NOT be assembled
#endif

#undef MYVAL
#ifndef MYVAL
    // This code in this block will be assembled
#endif
```

4.5.3.2.2.10 End If (#endif) Command

The “#endif” command is used to close a previously open #ifdef or #ifndef, thus closing the conditional assembly block.

4.5.3.2.2.11 Else (#else) Command

The “#else” command is used to specify a block of conditional code based on a previous #ifdef or #ifndef, allowing for the opposite case. For example:

```
#define MYVAL 1
#ifdef MYVAL
    // This code in this block will be assembled
#else
    // This code in this block will NOT be assembled
#endif
```

Copyright © 2011, Texas Instruments Incorporated

4.5.3.2.3 Labels

Labels are used denote program addresses. When placed at the beginning of a source line and immediately followed by a colon ':', they mark a program address location. When referenced by an instruction, the corresponding marked address is substituted for the label.

The syntax rules for labels are as follows:

- A label definition must be immediately followed by a colon.
- Only instructions and/or comments can occupy the same source line as a label.
- Labels can use characters 'A'-'Z', 'a'-'z', '0'-'9' plus underscores '_' and dots '.'.
- A label can not begin with a number ('0'-'9').

The following illustrates defining and using the label named "loop_label":

```
        ldi     r0, 100
loop_label:
        sub     r0, r0, 1
        qbne    loop_label, r0, 0
        ret
```

4.5.3.2.4 Comments

In PASM comments are transparent to all other operations, thus they can appear anywhere on any source line. However, since comments are terminated by the end of line, they are by definition, the last field on a line.

The syntax rules for comments are as follows:

- Comments must be preceded by '//'.
- Comments are always the last field to appear on a line.

The following illustrates defining a comment:

```
      //-------------------------
      // This is a comment
      //-------------------------
      ldi     r0, 100     // This is a comment
```

4.5.3.2.5 PRU Assembly Instructions

Instruction lines include a PRU mnemonic, followed by a list of parameters appropriate for the mnemonic. See Section 4.5.3.4, *PRU Instruction Set*, for supported instructions. Note that some of these are pseudo ops, which do not affect their use, but may affect how they are displayed when disassembled by a debugger.

4.5.3.2.5.1 Syntax

An instruction line consists of a mnemonic is followed by a specific number of parameters appropriate for the instruction. Parameters are always separated by commas. For example:

```
mnemonic  parameter1, parameter2, parameter3, parameter4
```

Each instruction accepts either a fixed or varying number of parameters. Those that use a varying number of parameters do so for either flexibility in formatting, or to adjust to different use cases. In most cases, at least one of the parameters can be one of a couple different types. For example, on many instructions the third parameter can be either a register or an immediate value.

All parameters take the form a register, label, or immediate value. There exists both a formal and informal syntax for instruction lines. The formal syntax was inherited from an earlier assembler. Modern applications typically use the informal syntax. These are discussed in more detail later in section dealing with parameter type, but here are some examples of both formal and informal syntax.

Formal Syntax:

```
      LDI     R2, #5
      LDI     R3, #3
      ADD     R1, R2, R3
```

Copyright © 2011, Texas Instruments Incorporated

```
QBNE    (LABEL), R1, #8
JMP     (LABEL)
```

Informal Syntax:

```
ldi     r2, 5
ldi     r3, 3
add     r1, r2, r3
qbne    label, r1, 8
jmp     label
```

4.5.3.2.5.2 Registers

The PASM assembler treats PRU registers as bit fields within the register file. All registers start with a base register (R0 through R31). A base register defines an unsigned 32 bit quantity. This 32 bit base field can be modified by appending different register modifier suffixes. The modifier suffix selects which portion of the register on which to operate. The suffixes are as follows:

Suffix	Range of n	Meaning
.w*n*	0 to 2	16 bit field with a byte offset of n within the parent field
.b*n*	0 to 3	8 bit field with a byte offset of n within the parent field
.t*n*	0 to 31	1 bit field with a bit offset of n within the parent field

Multiple suffixes may appear on a base register to further modify the desired field. For example:

Register	Meaning
R5	32 bit value, bits 0 to 32 of register R5
R5.w0	16 bit value, bits 0 to 15 of register R5
R5.w1	16 bit value, bits 8 to 23 of register R5
R5.b1	8 bit value, bits 8 to 15 of register R5
R5.t7	1 bit value, bit 7 of register R5
R5.w1.b1	8 bit value, bits 8 to 15 of “R5.w1” (this corresponds to bits 16 to 23 of register R5)
R5.w1.b1.t7	1 bit value, bit 7 of R5.w1.b1 (since R5.w1.b1 is bits 16 to 23 of R5, this is bit 23 of register R5)

Note that some suffix combinations are illegal. A combination is illegal when a modifier attempts to extract a field that is not contained in the parent field. For example:

Illegal Register	Reason for Illegality
R5.t0.b0	A byte field can be extracted from a single bit field
R5.w2.b2	Bits 16 to 23 can not be extracted out of a 16 bit field
R5.b0.t8	Bit 8 can not be extracted out of an 8 bit field
R5.w0.w1	Bits 8 to 23 can not be extracted out of a 16 bit field. Note that R5.w1.w0 would be legal, but not of much use as R5.w1.w0 == R5.w1

4.5.3.2.5.3 Loop/Byte Count Registers

Register R0 is used in some instructions to specify a loop count or byte count value. A count of this type is always the last parameter in the parameter list. A loop/byte count is always an 8 bit sub-field of R0. For legacy reasons, the register is expressed only by its modifier suffix. For example: “b0” is taken to mean “R0.b0” and “b2” is taken to mean “R0.b2”.

Copyright © 2011, Texas Instruments Incorporated

Register loop/byte counts are allowed only in very specific circumstances which are detailed in the appropriate instruction description.

Copyright © 2011, Texas Instruments Incorporated

4.5.3.2.5.4 Labels

Labels are used to reference code locations in a program. In PASM, labels are used to specify targets of jump instructions, but can also be used in an instruction that calls for an immediate value (so long as the label's value fits in the immediate field's specified bit width). When specifying a label, the user has the option of enclosing it in parenthesis "( )" for legacy concerns, but it is not required or recommended. For example:

```
QBNE    (MyLabel), R1, #8
JMP     (MyLabel)
LDI     R1.W0, #MyLabel
qbne    MyLabel, r1, 8
jmp     MyLabel
ldi     r1.w0, MyLabel
```

4.5.3.2.5.5 Immediate Values

Immediate values are simple numbers or expressions that compute to constant values. Immediate values or expressions can be preceded by a hash character '#' for legacy concerns, but this is not required or recommended. For example:

```
LDI     R1, #0x25
and     r2, r1, 0b1001011
ldi     r1.w0, 0x12345678 & 0xFFFF
ldi     r1.w2, 0x12345678 >> 16
add     r2, r3, (6*(5-3)/2) << 2
```

Note that if an immediate value is lead by a '0' without a format notation of 'x' or 'b', then the base is assumed to be in octal format.

4.5.3.2.5.6 Syntax Terms and Definitions

The following terms are definitions are used to specify parameters in a formal instruction definition.

Field Name	Meaning	Examples
REG, REG1, REG2, …	Any register field from 8 to 32 bits	r0 r1.w0 r3.b2
Rn, Rn1, Rn2, …	Any 32 bit register field (r0 through r31)	r0 r1
Rn.tx	Any 1 bit register field (x denotes the bit position)	r0.t23 r1.b1.t4
Cn, Cn1, Cn2, …	Any 32 bit constant register entry (c0 through c31)	c0 c1
bn	Specifies a field that must be b0, b1, b2, or b3 – denoting r0.b0, r0.b1, r0.b2, and r0.b3 respectively.	b0
LABEL	Any valid label, specified with or without parenthesis. An immediate value denoting an instruction address is also acceptable.	loop1 (loop1) 0
IM(n)	An immediate value from 0 to n. Immediate values can be specified with or without a leading hash "#" character. Immediate values, labels, and register addresses are all acceptable.	#23 0b0110 2+2 &r3.w2
OP(n)	This is a combination (or the union) of REG and IM(n). It specifies a register field from 8 to 32 bits, or an immediate value from 0 to n. A label or register address that resolves to a value within the denoted range is also acceptable.	r0 r1.w0 #0x7F 1<<3 loop1 &r1.w0

Copyright © 2011, Texas Instruments Incorporated

For example the following is the definition for the ADD instruction:

```
ADD REG1, REG2, OP(255)
```

This means that the first and second parameters can be any register field from 8 to 32 bits. The third parameter can be any register field from 8 to 32 bits or an immediate value from 0 to 255. Thus the following are all legal ADD instructions:

```
ADD     R1, R1, #0x25        // r1 += 37
ADD     r1, r1, 0x25         // r1 += 37
ADD     r3, r1, r2           // r3 = r1 + r2
ADD     r1.b0, r1.b0, 0b100  // r1.b0 += 4
ADD     r2, r1.w0, 1<<3      // r2 = r1.w0 + 8
```

4.5.3.3 Advanced Topics

4.5.3.3.1 Using Macros

Macros are used to define custom instructions for the CPU. They are similar to in-line subroutines in C.

4.5.3.3.1.1 Defining a Macro

A macro is defined by first declaring the start of a macro block and specifying the macro name, then specifying the assembly code to implement the intended function, and finally closing the macro block.

```
.macro  macro name
.mparam macro parameters
        < lines of assembly code >
        < lines of assembly code >
        < lines of assembly code >
.endm
```

The assembly code within a macro block is identical to that used outside a macro block with minor variances:

- Macros cannot be nested
- No dot commands may appear within a macro block other than “.mparam”.
- Pre-processor definitions and conditional assembly are processed when the macro is defined.
- Structure references are expanded when the macro is used.
- Labels defined within a macro are considered local and can only be referenced from within the macro.
- References to external labels from within a macro are allowed.

Copyright © 2011, Texas Instruments Incorporated

4.5.3.3.1.2 Macro Parameters

The macro parameters can be specified on one ".mparam" line or multiple. They are processed in the order that they are encountered. There are two types of parameters, mandatory and optional. Optional parameters are assigned a default value that is used in the event that they are not specified when the macro is used. Since parameters are always processed in order, any optional parameters must come last, and once an optional parameter is used, none of the remaining parameters may be specified.

For example:

```
.macro  mv1             // Define macro "mv1"
.mparam dst=r0, src=5   // Two optional parameters
    mov dst, src
.endm
```

For the above macro, the following expansions are possible:

Macro Invocation	Result
mv1 r1, 7	mov r1, 7
mv1 r2	mov r2, 5
mv1	mov r0, 5

Note that optional parameters can not be passed by using "empty" delimiters. For example, the following invocation of "mv1" is illegal:

```
        mv1      , 7     // Illegal attempt to do 'mov r0, 7'
```

4.5.3.3.1.3 Example Macros

4.5.3.3.1.3.1 Example 1: Move 32-bit Value (mov32)

The mov32 macro is a good example of a simple macro that saves some typing and makes a source code look a little cleaner.

Note: The latest assembler supports 32-bit immediate values natively, making this MACRO undesirable for general use (but it makes a good macro example).

Specification:

```
//
// mov32 : Move a 32bit value to a register
//
// Usage:
//     mov32   dst, src
//
// Sets dst = src. Src must be a 32 bit immediate value.
//
.macro  mov32
.mparam dst, src
        mov     dst.w0, (src) & 0xFFFF
        mov     dst.w2, (src) >> 16
.endm
```

Example Invocation:

The invocation for this macro is the same as the standard mov pseudo op:

```
        mov32   r0, 0x12345678
```

Example Expansion:

The expansion of the above invocation uses to immediate value moves to accomplish the 32-bit load.

```
        mov     r0.w0, (0x12345678) & 0xFFFF
        mov     r0.w2, (0x12345678) >> 16
```

Copyright © 2011, Texas Instruments Incorporated

4.5.3.3.1.3.2 Example 2: Quick Branch If in Range (qbir)

Any label defined within a macro is altered upon expansion to be unique. Thus internal labels are local to the macro and code defined outside of a macro cannot make direct use of a label that is defined inside a macro. However code contained within a macro can make free use of externally defined labels.

The qbir macro is a simple example that uses a local label. The macro instruction will jump to the supplied label if the test value is within the specified range.

Specification:

```
//
// qbir : Quick branch in range
//
// Usage:
//     qbir    label, test, low, high
//
// Jumps to label if (low <= test <= high).
// Test must be a register. Low and high can be
// a register or a 8 bit immediate value.
//
.macro  qbir
.mparam label, test, low, high
        qbgt    out_of_range, test, low
        qbge    label, test, high
out_of_range:
.endm
```

Example Invocation:

The example below checks the value in R5 for membership of two different ranges. Note that the range "low" and "high" values could also come from registers. They do not need to be immediate values:

```
        qbir    range1, r5,  1,  9   // Jump if (1 <= r5 <= 9)
        qbir    range2, r5, 25, 50   // Jump if (25 <= r5 <= 50)
```

Example Expansion:

The expansion of the above invocation illustrates how external labels are used unmodified while internal labels are altered on expansion to make them unique.

```
        qbgt     _out_of_range_1_, R5, 1
        qbge     range1, r5, 9
_out_of_range_1_:
        qbgt     _out_of_range_2_, R5, 25
        qbge     range2, r5, 50
_out_of_range_2_:
```

4.5.3.3.2 Using Structures and Scope

4.5.3.3.2.1 Basic Structures

Structures are used in PASM to eliminate the tedious process of defining structure offset fields for using in LBBO/SBBO, and the even more painful process of mapping structures to registers.

4.5.3.3.2.1.1 Declaring Structure Types

Structures are declared in PASM using the ".struct" dot command. This is similar to using a "typedef" in C. PASM automatically processes each declared structure template and creates an internal structure type. The named structure type is not yet associated with any registers or storage. For example, say the application programmer has the following structure in C:

```
typedef struct _PktDesc {
    struct _PktDesc *pNext;
    char            *pBuffer;
    unsigned short  Offset;
    unsigned short  BufLength;
    unsigned short  Flags;
    unsigned short  PktLength;
} PKTDESC;
```

The equivalent PASM structure type is created using the following syntax:

```
.struct PktDesc
    .u32    pNext
    .u32    pBuffer
    .u16    Offset
    .u16    BufLength
    .u16    Flags
    .u16    PktLength
.ends
```

4.5.3.3.2.1.2 Assigning Structure Interfaces to Registers

The second function of the PASM structure is to allow the application developer to map structures onto the PRU register file without the need to manually allocate registers to each field. This is done through the ".assign" dot command. For example, say the application programmer performs the following assignment:

```
    .assign PktDesc, R4, R7, RxDesc   // Make sure this uses R4 thru R7
```

When PASM sees this assignment, it will perform three tasks for the application developer:

1. PASM will verify that the structure perfectly spans the declared range (in this case R4 through R7). The application developer can avoid the formal range declaration by substituting '*' for 'R7' above.
2. PASM will verify that all structure fields are able to be mapped onto the declared range without any alignment issues. If an alignment issue is found, it is reported as an error along with the field in question. Note that assignments can begin on any register boundary.
3. PASM will create an internal data type named "RxDesc", which is of type "PktDesc".

For the above assignment, PASM will use the following variable equivalencies. Note that PASM will automatically adjust for endian mode.

Variable	Little Endian
RxDesc	R4
RxDesc.pNext	R4
RxDesc.pBuffer	R5
RxDesc.Offset	R6.w0
RxDesc.BufLength	R6.w2
RxDesc.Flags	R7.w0
RxDesc.PktLength	R7.w2

Copyright © 2011, Texas Instruments Incorporated

For example the source line below will be converted to the output shown:

```
// Input Source Line
ADD     r20, RxDesc.pBuffer, RxDesc.Offset

// Output Source Line
ADD     r20, R5, R6.w0
```

4.5.3.3.2.2 SIZE and OFFSET Operators

SIZE and OFFSET are two useful operators that can be applied to either structure types or structure assignments. The SIZE operator returns the byte size of the supplied structure or structure field. The OFFSET operator returns the byte offset of the supplied field from the start of the structure.

4.5.3.3.2.2.1 SIZE Operator Example

Using the assignment example from the previous section, the following SIZE equivalencies would apply:

Variable Operation	Results
SIZE(PktDesc)	16
SIZE(PktDesc.pNext)	4
SIZE(PktDesc.pBuffer)	4
SIZE(PktDesc.Offset)	2
SIZE(PktDesc.BufLength)	2
SIZE(PktDesc.Flags)	2
SIZE(PktDesc.PktLength)	2
SIZE(RxDesc)	16
SIZE(RxDesc.pNext)	4
SIZE(RxDesc.pBuffer)	4
SIZE(RxDesc.Offset)	2
SIZE(RxDesc.BufLength)	2
SIZE(RxDesc.Flags)	2
SIZE(RxDesc.PktLength)	2

4.5.3.3.2.2.2 OFFSET Operator Example

Using the assignment example from the previous section, the following OFFSET equivalencies would apply:

Variable Operation	Results
OFFSET(PktDesc)	0
OFFSET(PktDesc.pNext)	0
OFFSET(PktDesc.pBuffer)	4
OFFSET(PktDesc.Offset)	8
OFFSET(PktDesc.BufLength)	10
OFFSET(PktDesc.Flags)	12
OFFSET(PktDesc.PktLength)	14
OFFSET(RxDesc)	0
OFFSET(RxDesc.pNext)	0
OFFSET(RxDesc.pBuffer)	4
OFFSET(RxDesc.Offset)	8
OFFSET(RxDesc.BufLength)	10
OFFSET(RxDesc.Flags)	12
OFFSET(RxDesc.PktLength)	14

Copyright © 2011, Texas Instruments Incorporated

4.5.3.3.2.3 Using Variable Scopes

On larger PASM applications, it is common for different structures to be applied to the same register range for use at different times in the code. For example, assume the programmer uses three structures, one called “global”, one called “init” and one called “work”. Assume that the global structure is always valid, but that the init and work structures do not need to be used at the same time.

The programmer could assign the structures as follows:

```
.assign struct_global,   R2, R8,  myGlobal
.assign struct_init      R9, R12, init      // Registers shared with "work"
.assign struct_work      R9, R13, work      // Registers shared with "init"
```

The program code may look something like the following:

```
Start:
     call InitGlobalData
     mov  init.suff, myGlobal.data                    Using R9 to R12 for "init" structure
     call InitProcessing
     qbbs InitComplete, init.flags.fComplete
DoWork:
     call LoadWorkRecord
     mov  r0, myGlobal.Status                         Using R9 to R13 for "work" structure
     qbeq type1, work.type, myGlobal.WorkType1
                              …
InitProcessing:
     mov  init.start, init.stuff
     set  init.flags.fComplete                        Using R9 to R12 for "init" structure
     ret
```

The code has been shaded to emphasize when the shared registers are being used for the “init” structure and when they are been used for the “work” structure. The above is quite legal, but in this example, PASM does not provide any enforcement for the register sharing. For example, assume the work section of the code contained a reference to the “init” structure:

```
DoWork:
     call LoadWorkRecord
     mov  r0, myGlobal.Status
     set init.flags.fWorkStarted                      The reference to "init" would not cause an
                                                      assembly error.
     qbeq type1, work.type, myGlobal.WorkType1
                              …
```

The above example would not result in an assembly error even though using the same registers for two different purposes at the same time would result in a functional error.

Copyright © 2011, Texas Instruments Incorporated

To solve this potential problem, named variable scopes can be defined in which the register assignments are to be made. For example, the above shared assignments can be revised to as shown below to include the creation of variable scopes:

```
.assign struct_global,   R2, R8,  myGlobal // Available in all scopes

.enter Init_Scope                          // Create new scope Init_Scope
    .assign struct_init  R9, R12, init     // Only available in Init_Scope
.leave Init_Scope                          // Leave scope Init_Scope

.enter Work_Scope                          // Create new scope Work_Scope
    .assign struct_work  R9, R13, work     // Only available in Work_Scope
.leave Work_Scope                          // Leave scope Work_Scope
```

Once the scopes have been defined, the structures assigned within can only be accessed while the scope is open. Previously defined scopes can be reopened via the ".using" command.

```
.using Init_Scope
Start:
     call InitGlobalData
     mov  init.suff, myGlobal.data                    Using "Init_Scope"
     call InitProcessing
     qbbs InitComplete, init.flags.fComplete
.leave Init_Scope
.using Work_Scope
DoWork:
     call LoadWorkRecord
     mov  r0, myGlobal.Status                         Using "Work_Scope"
     qbeq type1, work.type, myGlobal.WorkType1
                              …
.leave Work_Scope
.using Init_Scope
InitProcessing:
     mov  init.start, init.stuff
     set  init.flags.fComplete                        Using "Init_Scope"
     ret
.leave Init_Scope
```

When using scopes as in the above example, any attempted reference to a structure assignment made outside a currently open scope will result in an assembly error.

4.5.3.3.3 Register Addressing and Spanning

Certain PRU instructions act upon or affect more than a single register field. These include MVIx, ZERO, SCAN, LBxO, and SBxO. It is important to understand how register fields are packed into registers, and how these fields are addressed when using one of these PRU functions.

4.5.3.3.3.1 Little Endian Register Mapping

The registers of the PRU are memory mapped with the little endian byte ordering scheme. For example, say we have the following registers set to the given values:

R0 = 0x80818283

R1 = 0x84858687

The following table is the register mapping to byte offset in little endian:

Copyright © 2011, Texas Instruments Incorporated

Table 4-21. Register Byte Mapping in Little Endian

Byte Offset	0	1	2	3	4	5	6	7
Register Field	R0.b0	R0.b1	R0.b2	R0.b3	R1.b0	R1.b1	R1.b2	R1.b3
Example Value	0x83	0x82	0x81	0x80	0x87	0x86	0x85	0x84

There are three factors affected by register mapping and little endian mapping. There are register spans, the first byte affected in a register field, and register addressing. In addition, there are some alterations in PRU opcode encoding.

4.5.3.3.3.1.1 Register Spans

The concept of how the register file is spanned can be best viewed using the tables created in the example from section 3.3.1. Registers are spanned by incrementing the byte offset from the start of the register file for each subsequent byte.

For example assume we have the following registers set to their indicated values:

R0 = 0x80818283

R1 = 0x84858687

R2 = 0x00001000

If the instruction “SBBO R0.b2, R2, 0, 5” is executed, it will result in a memory write to memory address 0x1000 as shown in little endian:

Table 4-22. SBBO Result for Little Endian Mode

Byte Address	0x1000	0x1001	0x1002	0x1003	0x1004
Value	0x81	0x80	0x87	0x86	0x85

4.5.3.3.3.1.2 First Byte Affected

The first affected byte in a register field is literally the first byte to be altered when executing a PRU instruction. For example, in the instruction “LBBO R0, R1, 0, 4”, the first byte to be affected by the LBBO is R0.b0 in little endian. The width of a field in a register span operation is almost irrelevant in little endian, since the first byte affected is independent of field width. For example, consider the following table:

Table 4-23. First Byte Affected in Little Endian Mode

Register Expression	First Byte Affected
R0	R0.b0
R0.w0	R0.b0
R0.w1	R0.b1
R0.w2	R0.b2
R0.b0	R0.b0
R0.b1	R0.b1
R0.b2	R0.b2
R0.b3	R0.b3

As can be seen in the table above, for any expression the first byte affected is always the byte offset of the field within the register. Thus in little endian, the expressions listed below all result in identical behavior.

- LBBO R0, R1, 0, 4
- LBBO R0.w0, R1, 0, 4
- LBBO R0.b0, R1, 0, 4

Copyright © 2011, Texas Instruments Incorporated

4.5.3.3.3.1.3 Register Address

The MVIx, ZERO, SCAN, LBxO, and SBxO instructions may use or require a register address instead of the direct register field in the instruction. In the assembler a leading '&' character is used to specify that a register address is to be used. The address of a register is defined to be the byte offset within the register file of the first affected byte in the supplied field.

Given the information already presented in this chapter, it should be straight forward to verify the following register address mappings:

Table 4-24. Register Addressing in Little Endian

Register Address Expression	Little Endian	
	First Byte Affected	Register Address
&Rn	Rn.b0	(n*4)
&Rn.w0	Rn.b0	(n*4)
&Rn.w1	Rn.b1	(n*4) + 1
&Rn.w2	Rn.b2	(n*4) + 2
&Rn.b0	Rn.b0	(n*4)
&Rn.b1	Rn.b1	(n*4) + 1
&Rn.b2	Rn.b2	(n*4) + 2
&Rn.b3	Rn.b3	(n*4) + 3

Register addresses are very useful for writing endian agnostic code, or for overriding the declared field widths in a structure element.

4.5.3.3.3.1.4 PRU Opcode Generation

The PRU binary opcode formats for LBBO, SBBO, LBCO, and SBCO use a byte offset for the source/destination register in the PRU register file. For example, only the following destination fields can actually be encoded into a PRU opcode for register R1:

- LBBO R1.b0, R0, 0, 4
- LBBO R1.b1, R0, 0, 4
- LBBO R1.b2, R0, 0, 4
- LBBO R1.b3, R0, 0, 4

Copyright © 2011, Texas Instruments Incorporated

4.5.3.4 PRU Instruction Set

4.5.3.4.1 Arithmetic and Logical

All operations are 32 bits wide (with a 33-bit result in the case of arithmetic). The source values are zero extended prior to the operation. If the destination is too small to accept the result, the result is truncated.

On arithmetic operations, the first bit to the right of the destination width becomes the carry value. Thus if the destination register is an 8 bit field, bit 8 of the result becomes the carry. For 16 and 32 bit destinations, bit 16 and bit 32 are used as the carry bit respectively.

4.5.3.4.1.1 Unsigned Integer Add (ADD)

Performs 32-bit add on two 32 bit zero extended source values.

Definition:

```
ADD REG1, REG2, OP(255)
```

Operation:

```
REG1 = REG2 + OP(255)
carry   = (( REG2 + OP(255) ) >> bitwidth(REG1)) & 1
```

Example:

```
add     r3, r1, r2
add     r3, r1.b0, r2.w2
add     r3, r3, 10
```

4.5.3.4.1.2 Unsigned Integer Add with Carry (ADC)

Performs 32-bit add on two 32 bit zero extended source values, plus a stored carry bit.

Definition:

```
ADC REG1, REG2, OP(255)
```

Operation:

```
REG1 = REG2 + OP(255) + carry
carry   = (( REG2 + OP(255) + carry ) >> bitwidth(REG1)) & 1
```

Example:

```
adc     r3, r1, r2
adc     r3, r1.b0, r2.w2
adc     r3, r3, 10
```

4.5.3.4.1.3 Unsigned Integer Subtract (SUB)

Performs 32-bit subtract on two 32 bit zero extended source values.

Definition:

```
SUB REG1, REG2, OP(255)
```

Operation:

```
REG1 = REG2 - OP(255)
carry   = (( REG2 - OP(255) ) >> bitwidth(REG1)) & 1
```

Example:

```
sub     r3, r1, r2
sub     r3, r1.b0, r2.w2
sub     r3, r3, 10
```

4.5.3.4.1.4 Unsigned Integer Subtract with Carry (SUC)

Performs 32-bit subtract on two 32 bit zero extended source values with carry (borrow).

Definition:

Copyright © 2011, Texas Instruments Incorporated

```
SUC REG1, REG2, OP(255)
```

Operation:

```
REG1 = REG2 - OP(255) - carry
carry   = (( REG2 - OP(255) - carry ) >> bitwidth(REG1)) & 1
```

Example:

```
suc     r3, r1, r2
suc     r3, r1.b0, r2.w2
suc     r3, r3, 10
```

4.5.3.4.1.5 Reverse Unsigned Integer Subtract (RSB)

Performs 32-bit subtract on two 32 bit zero extended source values. Source values reversed.

Definition:

```
RSB REG1, REG2, OP(255)
```

Operation:

```
REG1 = OP(255) - REG2
carry   = (( OP(255) - REG2 ) >> bitwidth(REG1)) & 1
```

Example:

```
rsb     r3, r1, r2
rsb     r3, r1.b0, r2.w2
rsb     r3, r3, 10
```

4.5.3.4.1.6 Reverse Unsigned Integer Subtract with Carry (RSC)

Performs 32-bit subtract on two 32 bit zero extended source values with carry (borrow). Source values reversed.

Definition:

```
RSC REG1, REG2, OP(255)
```

Operation:

```
REG1 = OP(255) - REG2 - carry
carry   = (( OP(255) - REG2 - carry ) >> bitwidth(REG1)) & 1
```

Example:

```
rsc     r3, r1, r2
rsc     r3, r1.b0, r2.w2
rsc     r3, r3, 10
```

4.5.3.4.1.7 Logical Shift Left (LSL)

Performs 32-bit shift left of the zero extended source value.

Definition:

```
LSL REG1, REG2, OP(31)
```

Operation:

```
REG1 = REG2 << ( OP(31) & 0x1f )
```

Example:

```
lsl     r3, r3, 2
lsl     r3, r3, r1.b0
lsl     r3, r3.b0, 10
```

4.5.3.4.1.8 Logical Shift Right (LSR)

Performs 32-bit shift right of the zero extended source value.

Definition:

Copyright © 2011, Texas Instruments Incorporated

```
LSR REG1, REG2, OP(31)
```

Operation:

```
REG1 = REG2 >> ( OP(31) & 0x1f )
```

Example:

```
lsr     r3, r3, 2
lsr     r3, r3, r1.b0
lsr     r3, r3.b0, 10
```

4.5.3.4.1.9 Bitwise AND (AND)

Performs 32-bit logical AND on two 32 bit zero extended source values.

Definition:

```
AND REG1, REG2, OP(255)
```

Operation:

```
REG1 = REG2 & OP(255)
```

Example:

```
and     r3, r1, r2
and     r3, r1.b0, r2.w2
and     r3.b0, r3.b0, ~(1<<3)    // Clear bit 3
```

4.5.3.4.1.10 Bitwise OR (OR)

Performs 32-bit logical OR on two 32 bit zero extended source values.

Definition:

```
OR REG1, REG2, OP(255)
```

Operation:

```
REG1 = REG2 | OP(255)
```

Example:

```
or      r3, r1, r2
or      r3, r1.b0, r2.w2
or      r3.b0, r3.b0, 1<<3     // Set bit 3
```

4.5.3.4.1.11 Bitwise Exclusive OR (XOR)

Performs 32-bit logical XOR on two 32 bit zero extended source values.

Definition:

```
XOR REG1, REG2, OP(255)
```

Operation:

```
REG1 = REG2 ^ OP(255)
```

Example:

```
xor      r3, r1, r2
xor      r3, r1.b0, r2.w2
xor      r3.b0, r3.b0, 1<<3   // Toggle bit 3
```

4.5.3.4.1.12 Bitwise NOT (NOT)

Performs 32-bit logical NOT on the 32 bit zero extended source value.

Definition:

```
NOT REG1, REG2
```

Operation:

```
REG1 = ~REG2
```

Copyright © 2011, Texas Instruments Incorporated

Example:

```
not      r3, r3
not      r1.w0, r1.b0
```

4.5.3.4.1.13 Copy Minimum (MIN)

Compares two 32 bit zero extended source values and copies the minimum value to the destination register.

Definition:

```
MIN REG1, REG2, OP(255)
```

Operation:

```
if( OP(255) > REG2 )
        REG1 = REG2;
else
        REG1 = OP(255);
```

Example:

```
min      r3, r1, r2
min      r1.w2, r1.b0, 127
```

4.5.3.4.1.14 Copy Maximum (MAX)

Compares two 32 bit zero extended source values and copies the maximum value to the destination register.

Definition:

```
MAX REG1, REG2, OP(255)
```

Operation:

```
if( OP(255) > REG2 )
        REG1 = REG2;
else
        REG1 = OP(255);
```

Example:

```
max      r3, r1, r2
max      r1.w2, r1.b0, 127
```

4.5.3.4.1.15 Clear Bit (CLR)

Clears the specified bit in the source and copies the result to the destination. Various calling formats are supported:

Format 1:

Definition:

```
CLR REG1, REG2, OP(255)
```

Operation:

```
REG1 = REG2 & ~( 1 << (OP(31) & 0x1f) )
```

Example:

```
clr      r3, r1, r2          // r3 = r1 & ~(1<<r2)
clr      r1.b1, r1.b0, 5     // r1.b1 = r1.b0 & ~(1<<5)
```

Format 2 (same source and destination):

Definition:

```
CLR REG1, OP(255)
```

Operation:

```
REG1 = REG1 & ~( 1 << (OP(31) & 0x1f) )
```

Copyright © 2011, Texas Instruments Incorporated

Example:

```
clr      r3, r1             // r3 = r3 & ~(1<<r1)
clr      r1.b1, 5           // r1.b1 = r1.b1 & ~(1<<5)
```

Format 3 (source abbreviated):

Definition:

```
CLR REG1, Rn.tx
```

Operation:

```
REG1 = Rn & ~Rn.tx
```

Example:

```
clr      r3, r1.t2         // r3 = r1 & ~(1<<2)
clr      r1.b1, r1.b0.t5   // r1.b1 = r1.b0 & ~(1<<5)
```

Copyright © 2011, Texas Instruments Incorporated

Format 4 (same source and destination – abbreviated):

Definition:

```
CLR Rn.tx
```

Operation:

```
Rn = Rn & ~Rn.tx
```

Example:

```
clr      r3.t2            // r3 = r3 & ~(1<<2)
```

4.5.3.4.1.16 Set Bit

Sets the specified bit in the source and copies the result to the destination. Various calling formats are supported.

Note: Whenever R31 is selected as the source operand to a SET, the resulting source bits will be NULL, and not reflect the current input event flags that are normally obtained by reading R31.

Format 1:

Definition:

```
SET REG1, REG2, OP(255)
```

Operation:

```
REG1 = REG2 | ( 1 << (OP(31) & 0x1f) )
```

Example:

```
set      r3, r1, r2          // r3 = r1 | (1<<r2)
set      r1.b1, r1.b0, 5     // r1.b1 = r1.b0 | (1<<5)
```

Format 2 (same source and destination):

Definition:

```
SET REG1, OP(255)
```

Operation:

```
REG1 = REG1 | ( 1 << (OP(31) & 0x1f) )
```

Example:

```
set      r3, r1              // r3 = r3 | (1<<r1)
set      r1.b1, 5            // r1.b1 = r1.b1 | 1<<5)
```

Format 3 (source abbreviated):

Definition:

```
SET REG1, Rn.tx
```

Operation:

```
REG1 = Rn | Rn.tx
```

Example:

```
set      r3, r1.t2          // r3 = r1 | (1<<2)
set      r1.b1, r1.b0.t5    // r1.b1 = r1.b0 | (1<<5)
```

Format 4 (same source and destination – abbreviated):

Definition:

```
SET Rn.tx
```

Operation:

```
Rn = Rn | Rn.tx
```

Example:

```
set      r3.t2              // r3 = r3 | (1<<2)
```

Copyright © 2011, Texas Instruments Incorporated

4.5.3.4.1.17 Left-Most Bit Detect (LMBD)

Scans REG2 from its left-most bit for a bit value matching bit 0 of OP(255), and writes the bit number in REG1 (writes 32 to REG1 if the bit is not found).

Definition:

```
LMBD REG1, REG2, OP(255)
```

Operation:

```
for( i=(bitwidth(REG2)-1); i>=0; i-- )
if( !((( REG2>>i) ^ OP(255))&1) )
    break;
if( i<0 )
    REG1 = 32;
else
    REG1 = i;
```

Example:

```
lmbd     r3, r1, r2
lmbd     r3, r1, 1
lmbd     r3.b3, r3.w0, 0
```

4.5.3.4.1.18 NULL Operation (NOP*n*)

This instruction performs no standard operation. The instruction may or may not provide custom functionality that will vary from platform to platform.

There are 16 forms of the instruction including NOP0 through NOP9, and NOPA through NOPF.

Definition:

```
NOPn REG1, REG2, OP(255)
```

Operation:

```
NULL operation or Platform dependent
```

Example:

```
nop0     r3, r1, r2
nop9     r3, r1.b0, r2.w2
nopf     r3, r3, 10
```

4.5.3.4.2 Register Load and Store

4.5.3.4.2.1 Copy Value (MOV)

The MOV instruction moves the value from OP(0xFFFFFFFF), zero extends it, and stores it into REG1. The instruction is a pseudo op, and is coded with different PRU instructions, depending on how it is used. When used with a constant, it is similar to the LDI instruction except that it allows for moving values up to 32-bits by automatically inserting two LDI instructions. It will always select the optimal coding method to perform the desired operation.

Definition:

```
MOV REG1, OP(0xFFFFFFFF)
```

Operation:

```
REG1 = OP(0xFFFFFFFF)
```

Example:

```
mov     r3, r1
mov     r3, r1.b0        // Zero extend r1.b0 into r3
mov     r1, 10           // Move 10 into r1
mov     r1, #10          // Move 10 into r1
mov     r1, 0b10 + 020/2 // Move 10 into r1
mov     r1, 0x12345678   // Move 0x12345678 into r1
mov     r30.b0, &r2      // Move the offset of r2 into r30.b0
```

Copyright © 2011, Texas Instruments Incorporated

4.5.3.4.2.2 Load Immediate (LDI)

The LDI instruction moves the value from IM(65535), zero extends it, and stores it into REG1. This instruction is one form of MOV (the MOV pseudo op uses LDI when the source data is an immediate value).

Definition:

```
LDI REG1, IM(65535)
```

Operation:

```
REG1 = IM(65535)
```

Example:

```
ldi     r1, 10           // Load 10 into r1
ldi     r1, #10          // Load 10 into r1
ldi     r1, 0b10 + 020/2 // Load 10 into r1
ldi     r30.b0, &r2      // Load the offset of r2 into r30.b0
```

4.5.3.4.2.3 Move Register File Indirect (MVIx)

The MVIx instruction family moves an 8-, 16-, or 32-bit value from the source to the destination. The size of the value is determined by the exact instruction used; MVIB, MVIW, and MVID, for 8-, 16-, and 32-bit values respectively. The source, destination, or both can be register pointers. There is an option for auto-increment and auto-decrement on register pointers.

Definition:

```
MVIB    [*][&][--]REG1[++], [*][&][--]REG2[++]
MVIW    [*][&][--]REG1[++], [*][&][--]REG2[++]
MVID    [*][&][--]REG1[++], [*][&][--]REG2[++]
```

Operation:

- Register pointers are byte offsets into the register file
- Auto increment and decrement operations are done by the byte width of the operation
  - Increments are post-increment; incremented after the register offset is used
  - Decrements are pre-decrement; decremented before the register offset is used
- When the destination register is not expressed as register pointer, the size of the data written is determined by the field width of the destination register. If the data transfer size is less than the width of the destination, the data is zero extended. Size conversion occurs after indirect reads, and before indirect writes.
- When the source register is not expressed as a register pointer, the size of the data read is the lesser of register source width and the instruction width. For example, a MVIB from R0 will read only 8 bits from R0.b3, and a MVID from R0.b3 will read 8 bits from R0.b3 (and then zero extend it to a 32-bit value).

Note that register pointer registers are restricted to r1.b0, r1.b1, r1.b2, and r1.b3.

4.5.3.4.2.3.1 Notes on Endian Mode and Size Conversion

On an indirect read operation, the data is first read indirectly using the source pointer. The resulting data size is the size specified by the MVIx opcode. It is then converted to the destination register size using truncation or zero extend.

Say we have the following registers set:

```
R1.b0 = 8 (this is &R2)
R2 = 0x01020304
R3 = 0
```

The following are some indirect read examples:

Copyright © 2011, Texas Instruments Incorporated

Operation	Result
	Little Endian
mvib r3, *r1.b0	R3 = 0x00000004
mviw r3, *r1.b0	R3 = 0x00000304
mvid r3, *r1.b0	R3 = 0x01020304
mvid r3.w0, *r1.b0	R3 = 0x00000304
mvid r3.b0, *r1.b0	R3 = 0x00000004

On an indirect write operation, the data is first converted to the size as specified by the MVIx opcode using zero extend or truncation. It is then written indirectly using the destination pointer.

Say we have the following registers set:

```
R1.b0 = 8 (this is &R2)
R2 = 0
R3 = 0x01020304
```

The following are some indirect write examples:

Operation	Result
	Little Endian
mvib *r1.b0, r3	R2 = 0x00000004
mviw *r1.b0, r3	R2 = 0x00000304
mvid *r1.b0, r3	R2 = 0x01020304
mvid *r1.b0, r3.w0	R2 = 0x00000304
mvid *r1.b0, r3.b0	R2 = 0x00000004

4.5.3.4.2.4 Load Byte Burst (LBBO)

The LBBO instruction is used to read a block of data from memory into the register file. The memory address to read from is specified by a 32 bit register (Rn2), using an optional offset. The destination in the register file can be specified as a direct register, or indirectly through a register pointer.

Note: Either the traditional direct register syntax or the more recent register address offset syntax can be used for the first parameter.

Format 1 (immediate count):

Definition:

```
LBBO REG1, Rn2, OP(255), IM(124)
```

Operation:

```
memcpy( offset(REG1), Rn2+OP(255), IM(124) );
```

Example:

```
lbbo     r2, r1, 5, 8      // Copy 8 bytes into r2/r3 from the
                           // memory address r1+5

lbbo     &r2, r1, 5, 8     // Copy 8 bytes into r2/r3 from the
                           // memory address r1+5
```

Format 2 (register count):

Definition:

```
LBBO REG1, Rn2, OP(255), bn
```

Operation:

```
memcpy( offset(REG1), Rn2+OP(255), bn );
```

Example:

```
lbbo     r3, r1, r2.w0, b0 // Copy "r0.b0" bytes into r3 from the
                           // memory address r1+r2.w0
```

Copyright © 2011, Texas Instruments Incorporated

```
lbbo     &r3, r1, r2.w0, b0 // Copy "r0.b0" bytes into r3 from the
                            // memory address r1+r2.w0
```

4.5.3.4.2.5 Store Byte Burst (SBBO)

The SBBO instruction is used to write a block of data from the register file into memory. The memory address to write to is specified by a 32 bit register (Rn2), using an optional offset. The source in the register file can be specified as a direct register, or indirectly through a register pointer.

Note: Either the traditional direct register syntax or the more recent register address offset syntax can be used for the first parameter.

Format 1 (immediate count):

Definition:

```
SBBO REG1, Rn2, OP(255), IM(124)
```

Operation:

```
memcpy( Rn2+OP(255), offset(REG1), IM(124) );
```

Example:

```
sbbo     r2, r1, 5, 8      // Copy 8 bytes from r2/r3 to the
                           // memory address r1+5

sbbo     &r2, r1, 5, 8     // Copy 8 bytes from r2/r3 to the
                           // memory address r1+5
```

Format 2 (register count):

Definition:

```
SBBO REG1, Rn2, OP(255), bn
```

Operation:

```
memcpy( Rn2+OP(255), offset(REG1), bn );
```

Example:

```
sbbo     r3, r1, r2.w0, b0 // Copy "r0.b0" bytes from r3 to the
                           // memory address r1+r2.w0

sbbo     &r3, r1, r2.w0, b0 // Copy "r0.b0" bytes from r3 to the
                            // memory address r1+r2.w0
```

4.5.3.4.2.6 Load Byte Burst with Constant Table Offset (LBCO)

The LBCO instruction is used to read a block of data from memory into the register file. The memory address to read from is specified by a 32 bit constant register (Cn2), using an optional offset from an immediate or register value. The destination in the register file is specified as a direct register.

Note: Either the traditional direct register syntax or the more recent register address offset syntax can be used for the first parameter.

Format 1 (immediate count):

Definition:

```
LBCO REG1, Cn2, OP(255), IM(124)
```

Operation:

```
memcpy( offset(REG1), Cn2+OP(255), IM(124) );
```

Example:

```
lbco     r2, c1, 5, 8      // Copy 8 bytes into r2/r3 from the
                           // memory address c1+5

lbco     &r2, c1, 5, 8     // Copy 8 bytes into r2/r3 from the
                           // memory address c1+5
```

Copyright © 2011, Texas Instruments Incorporated

Format 2 (register count):

Definition:

```
LBCO REG1, Cn2, OP(255), bn
```

Operation:

```
memcpy( offset(REG1), Cn2+OP(255), bn );
```

Example:

```
lbco     r3, c1, r2.w0, b0 // Copy "r0.b0" bytes into r3 from the
                           // memory address c1+r2.w0

lbco     &r3, c1, r2.w0, b0 // Copy "r0.b0" bytes into r3 from the
                            // memory address c1+r2.w0
```

4.5.3.4.2.7 Store Byte Burst with Constant Table Offset (SBCO)

The SBCO instruction is used to write a block of data from the register file into memory. The memory address to write to is specified by a 32 bit constant register (Cn2), using an optional offset from an immediate or register value. The source in the register file is specified as a direct register.

Note: Either the traditional direct register syntax or the more recent register address offset syntax can be used for the first parameter.

Format 1 (immediate count):

Definition:

```
SBCO REG1, Cn2, OP(255), IM(124)
```

Operation:

```
memcpy( Cn2+OP(255), offset(REG1), IM(124) );
```

Example:

```
sbco     r2, c1, 5, 8      // Copy 8 bytes from r2/r3 to the
                           // memory address c1+5

sbco     &r2, c1, 5, 8     // Copy 8 bytes from r2/r3 to the
                           // memory address c1+5
```

Format 2 (register count):

Definition:

```
SBCO REG1, Cn2, OP(255), bn
```

Operation:

```
SBCO REG1, Cn2, OP(255), bn
```

Example:

```
sbco     r3, c1, r2.w0, b0 // Copy "r0.b0" bytes from r3 to the
                           // memory address c1+r2.w0

sbco     &r3, c1, r2.w0, b0 // Copy "r0.b0" bytes from r3 to the
                            // memory address c1+r2.w0
```

Copyright © 2011, Texas Instruments Incorporated

4.5.3.4.2.8 Clear Register Space (ZERO)

Clear space in the register file (set to zero).

Definition:

```
ZERO IM(123), IM(124)
ZERO &REG1, IM(124)
```

Operation: The register file data starting at offset IM(123) (or &REG1) with a length of IM(124) is cleared to zero.

Example:

```
zero    0, 8     // Set R0 and R1 to zero
zero    &r0, 8   // Set R0 and R1 to zero
// Set all elements in myStruct zero
zero    &myStruct, SIZE(myStruct)
```

This pseudo-op is implemented using a form of the XFR instruction, and always completes in a single clock cycle.

4.5.3.4.2.9 Fill Register Space (FILL)

Set all bits in a register file range.

Definition:

```
FILL IM(123), IM(124)
FILL &REG1, IM(124)
```

Operation: The register file data starting at offset IM(123) (or &REG1) with a length of IM(124) is set to one.

Example:

```
fill    0, 8     // Set R0 and R1 to 0xFFFFFFFF
fill    &r0, 8   // Set R0 and R1 to 0xFFFFFFFF
// Set all elements in myStruct 0xFF
fill    &myStruct, SIZE(myStruct)
```

This pseudo-op will generate the necessary XFR instruction and will always complete in a single clock cycle.

4.5.3.4.2.10 Register Transfer In, Out, and Exchange (XIN, XOUT, XCHG)

These XFR pseudo-ops use the XFR wide transfer bus to read in a range of bytes into the register file, write out a range of bytes from the register file, or exchange the range of bytes to/from the register file.

Definition:

```
XIN    IM(253), REG, IM(124)
XIN    IM(253), REG, bn
XOUT    IM(253), REG, IM(124)
XOUT    IM(253), REG, bn
XCHG    IM(253), REG, IM(124)
XCHG    IM(253), REG, bn
```

Operation:

On XIN, the register file data starting at the register REG with a length of IM(124) is read in from the parallel XFR interface from the hardware device with the device id specified in IM(253).

On XOUT, the register file data starting at the register REG with a length of IM(124) is written out to the parallel XFR interface to the hardware device with the device id specified in IM(253).

On XCHG, the register file data starting at the register REG with a length of IM(124) is exchanged on the parallel XFR interface between the register file and the hardware device with the device id specified in IM(253).

Example:

```
XIN   XID_SCRATCH, R2, 8   // Read 8 bytes from scratch to R2:R3
XOUT  XID_SCRATCH, R2, b2  // Write ‘b2’ byte to scratch starting at R2
```

Copyright © 2011, Texas Instruments Incorporated

```
XCHG  XID_SCRATCH, R2, 8   // Exchange the values of R2:R3 with 8 bytes
                           // from scratch
XIN   XID_PKTFIFO, R6, 24  // Read 24 bytes from the "Packet FIFO"
                           // info R6:R7:R8:R9
```

4.5.3.4.2.11 Register and Status Transfer In, Out, and Exchange (SXIN, SXOUT, SXCHG)

These XFR pseudo-ops use the XFR wide transfer bus to read in a range of bytes into the register file, write out a range of bytes from the register file, or exchange the range of bytes to/from the register file. This version also transfers status along with any specified registers.

Definition:

```
SXIN    IM(253), REG, IM(124)
SXIN    IM(253), REG, bn
SXOUT    IM(253), REG, IM(124)
SXOUT    IM(253), REG, bn
SXCHG    IM(253), REG, IM(124)
SXCHG    IM(253), REG, bn
```

Operation: Operation of their instructions is identical to their non-status counterparts, except that core status is transferred along with any specified registers. Status includes things such as instruction pointer and the carry/borrow bit.

4.5.3.4.2.11.1 Notes on the Register Transfer Bus

All register transfers use the same fixed alignment. For example, the contents of R0.b3 may only be transferred to the exact byte location that is mapped to R0.b3 on the destination device. Although transfers ideally complete in one cycle, peripherals have the ability to stall the PRU when a transfer can not be completed.

A transfer can start and end on a register byte boundary, but must be contiguous. For example, a transfer of 9 bytes starting at R0.b1 will transfer the following bytes:

Endian Mode	Bytes Transferred (9 bytes starting with R0.b1)
Little Endian	R0.b1, R0.b2, R0.b3, R1.b0, R1.b1, R1.b2, R1.b3, R2.b0, R2.b1

Some peripherals may limit transfers to multiples of 4 bytes on word boundaries.

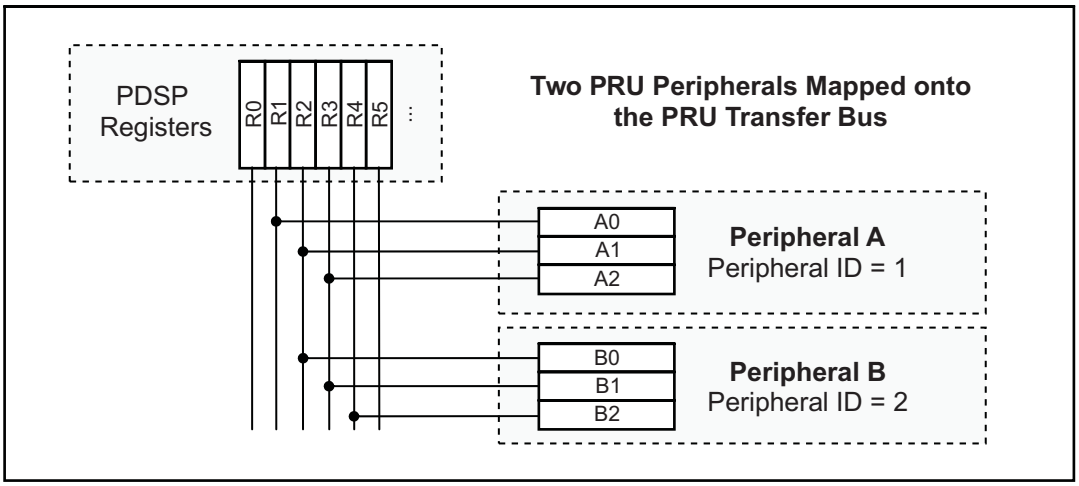
4.5.3.4.2.11.2 Transfer Bus Hardware Connection

The transfer bus coming out of the PRU consists of 124 bytes of data and a sufficient number of control lines to control the transfer. Any given transfer will consist of a direction (in or out of the PRU), a peripheral ID, a starting byte offset, and a length. These can be represented in hardware as register and byte enable signals as needed for a proper implementation (which is beyond the scope of this description).

How the bus transfer is used is entirely up to the peripherals that connect to it. The number of registers that are implemented on the peripheral and how they align to the PRU register file is determined by the peripheral connection. For example, the system below connects PRU registers R1::R3 to “peripheral A” registers A0::A2, and connects PRU registers R2::R4 to “peripheral B” registers B0::B2.

Copyright © 2011, Texas Instruments Incorporated

Figure 4-15. PRU Peripherals Mapped to PRU Transfer Bus



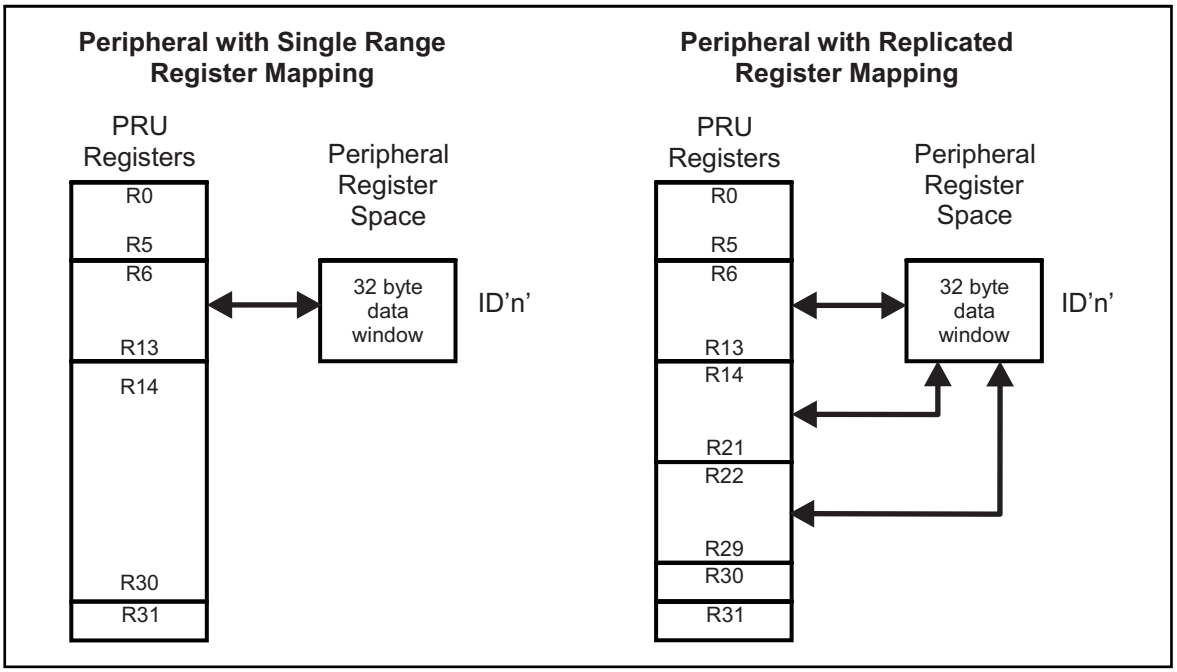
4.5.3.4.2.11.3 Device Register Mappings

Using the XFR command, the PRU can transfer register contents between its register file and externally connected peripherals. The transfer id used for the source and destination allows for up to 253 additional peripherals to be connected to the PRU with register transfer capability.

Not all peripherals will implement the entire 32 PRU register space, and any transfer from space that is not implemented on the peripheral will return undefined results. Peripherals that do not implement the full space can define which register range to implement, and can even replicated a smaller set of registers across the PRU register space.

The example below shows two possible implementations of a peripheral that only contains a 32 byte data window (8 registers). The first example has a straight register mapping. The second example maps three PRU register spans onto the same local peripheral space. This allows the PRU to transfer peripheral data to or from any one of the three possible spans, allowing for much greater flexibility in using the peripheral.

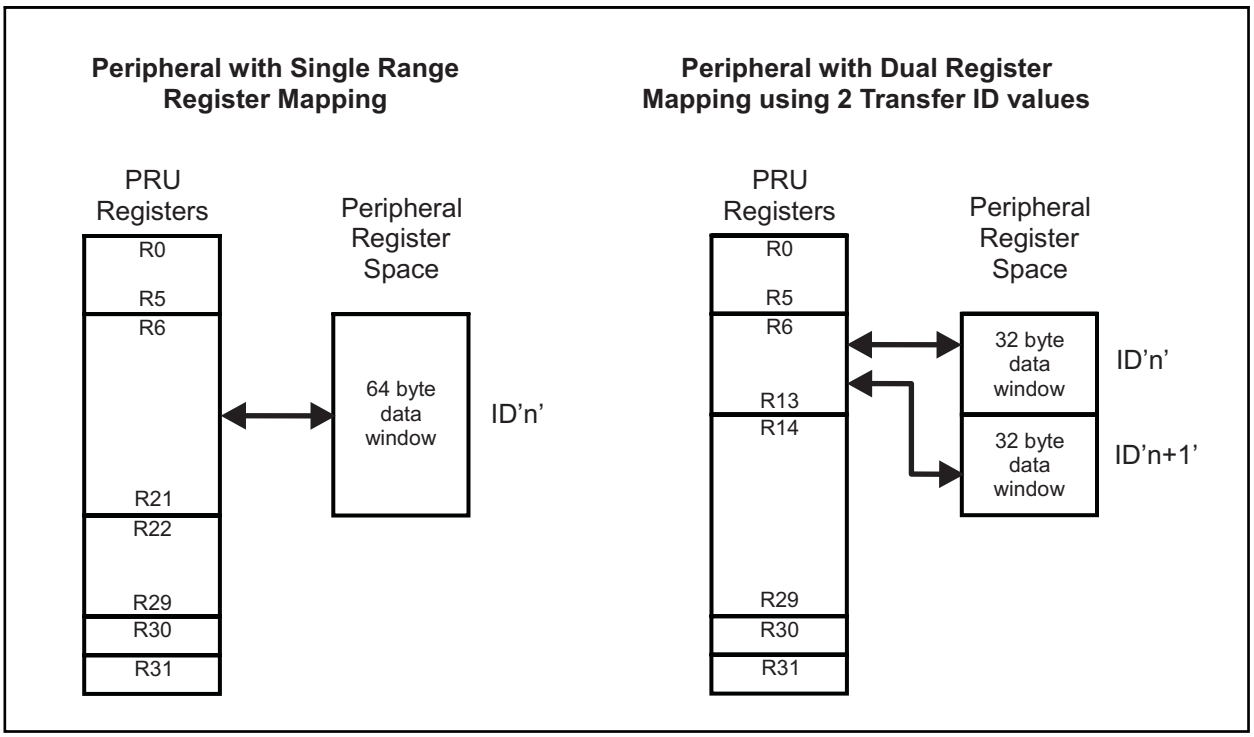
Figure 4-16. Possible Implementations of a 32-Byte Data Window Peripheral



Copyright © 2011, Texas Instruments Incorporated

It is also possible for a peripheral to map the same PRU registers into multiple internal device registers by using more that one peripheral ID. For example, below are two possible implementations of a peripheral with a 64 byte register space. The first uses a standard transfer, while the second makes use of 2 transfer ID values to allow the same PRU register span to be mapped to both of its internal register sets. Mapping the same PRU register space into multiple peripheral registers can benefit the PRU when the entire space need not be valid at any particular time. For example, a network packet search engine may map the Layer 2 fields to the same PRU register space at the Layer 3 fields, knowing that they both do not need to be valid at the same time and thus freeing up addition PRU registers for other use.

Figure 4-17. PRU Registers Mapped into Multiple Internal Device Registers



4.5.3.4.3 Flow Control

4.5.3.4.3.1 Unconditional Jump (JMP)

Unconditional jump to a 16 bit instruction address, specified by register or immediate value.

Definition:

```
JMP OP(65535)
```

Operation:

```
PRU Instruction Pointer = OP(65535)
```

Example:

```
jmp     r2.w0    // Jump to the address stored in r2.w0
jmp     myLabel  // Jump to the supplied code label
```

4.5.3.4.3.2 Unconditional Jump and Link (JAL)

Unconditional jump to a 16 bit instruction address, specified by register or immediate value. The address following the JAL instruction is stored into REG1, so that REG1 can later be used as a "return" address.

Definition:

```
JAL REG1, OP(65535)
```

Copyright © 2011, Texas Instruments Incorporated

Operation:

```
REG1 = Current PRU Instruction Pointer + 1
PRU Instruction Pointer = OP(65535)
```

Example:

```
jal     r2.w2, r2.w0      // Jump to the address stored in r2.w0
                          // put return location in r2.w2
jal     r30.w0, myLabel   // Jump to the supplied code label and
                          // put the return location in r30.w0
```

4.5.3.4.3.3 Call Procedure (CALL)

The CALL instruction is a pseudo op designed to emulate a subroutine call on a stack based processor. Here, the JAL instruction is used with a specific call/ret register being the location to save the return pointer. The default register is R30.w0, but this can be changed by using the .setcallreg dot command. This instruction works in conjunction with the ".ret" dot command (deprecated) or the RET pseudo op instruction.

Definition:

```
CALL OP(65535)
```

Operation:

```
JAL call register, OP(65535)   (where call register defaults to r30.w0)
```

Example:

```
call    r2.w0    // Call to the address stored in r2.w0
call    myLabel  // Call to the supplied code label
```

4.5.3.4.3.4 Return from Procedure (RET)

The RET instruction is a pseudo op designed to emulate a subroutine return on a stack based processor. Here, the JMP instruction is used with a specific call/ret register being the location of the return pointer. The default register is R30.w0, but this can be changed by using the .setcallreg dot command. This instruction works in conjunction with the CALL pseudo op instruction.

Definition:

```
RET
```

Operation:

```
JMP call register   (where call register defaults to r30.w0)
```

Example:

```
ret    // Return address stored in our call register
```

4.5.3.4.3.5 Quick Branch if Greater Than (QBGT)

Jumps if the value of OP(255) is greater than REG1.

Definition:

```
QBGT LABEL, REG1, OP(255)
```

Operation: Branch to LABEL if OP(255) > REG1

Example:

```
qbgt    myLabel, r2.w0, 5  // Branch if 5 > r2.w0
qbgt    myLabel, r3, r4    // Branch if r4 > r3
```

4.5.3.4.3.6 Quick Branch if Greater Than or Equal (QBGE)

Jumps if the value of OP(255) is greater than or equal to REG1.

Definition:

Copyright © 2011, Texas Instruments Incorporated

```
QBGE LABEL, REG1, OP(255)
```

Operation:

```
Branch to LABEL if OP(255) >= REG1
```

Example:

```
qbge    myLabel, r2.w0, 5  // Branch if 5 >= r2.w0
qbge    myLabel, r3, r4    // Branch if r4 >= r3
```

4.5.3.4.3.7 Quick Branch if Less Than (QBLT)

Jumps if the value of OP(255) is less than REG1.

Definition:

```
QBLT LABEL, REG1, OP(255)
```

Operation:

```
Branch to LABEL if OP(255) < REG1
```

Example:

```
qblt    myLabel, r2.w0, 5  // Branch if 5 < r2.w0
qblt    myLabel, r3, r4    // Branch if r4 < r3
```

4.5.3.4.3.8 Quick Branch if Less Than or Equal (QBLE)

Jumps if the value of OP(255) is less than or equal to REG1.

Definition:

```
QBLE LABEL, REG1, OP(255)
```

Operation:

```
Branch to LABEL if OP(255) <= REG1
```

Example:

```
qble    myLabel, r2.w0, 5  // Branch if 5 <= r2.w0
qble    myLabel, r3, r4    // Branch if r4 <= r3
```

4.5.3.4.3.9 Quick Branch if Equal (QBEQ)

Jumps if the value of OP(255) is equal to REG1.

Definition:

```
QBGT LABEL, REG1, OP(255)
```

Operation:

```
Branch to LABEL if OP(255) == REG1
```

Example:

```
qbeq    myLabel, r2.w0, 5  // Branch if r2.w0==5
qbeq    myLabel, r3, r4    // Branch if r4==r3
```

4.5.3.4.3.10 Quick Branch if Not Equal (QBNE)

Jumps if the value of OP(255) is NOT equal to REG1.

Definition:

```
QBNE LABEL, REG1, OP(255)
```

Operation:

```
Branch to LABEL if OP(255) != REG1
```

Example:

```
qbne    myLabel, r2.w0, 5  // Branch if r2.w0==5
qbne    myLabel, r3, r4    // Branch if r4!=r3
```

Copyright © 2011, Texas Instruments Incorporated

4.5.3.4.3.11 Quick Branch Always (QBA)

Jump always. This is similar to the JMP instruction, only QBA uses an address offset and thus can be relocated in memory.

Definition:

```
QBA LABEL
```

Operation:

```
Branch to LABEL
```

Example:

```
qba    myLabel      // Branch
```

4.5.3.4.3.12 Quick Branch if Bit is Set (QBBS)

Jumps if the bit OP(31) is set in REG1.

Format 1:

Definition:

```
QBBS LABEL, REG1, OP(255)
```

Operation:

```
Branch to LABEL if( REG1 & ( 1 <<  (OP(31) & 0x1f) ) )
```

Example:

```
qbbs     myLabel r3, r1     // Branch if( r3&(1<<r1) )
qbbs     myLabel, r1.b1, 5  // Branch if( r1.b1 & 1<<5 )
```

Format 2:

Definition:

```
QBBS LABEL, Rn.tx
```

Operation:

```
Branch to LABEL if( Rn & Rn.tx )
```

Example:

```
qbbs     myLabel, r1.b1.t5    // Branch if( r1.b1 & 1<<5 )
qbbs     myLabel, r0.t0    // Brach if bit 0 in R0 is set
```

4.5.3.4.3.13 Quick Branch if Bit is Clear (QBBC)

Jumps if the bit OP(31) is clear in REG1.

Format 1:

Definition:

```
QBBC LABEL, REG1, OP(255)
```

Operation:

```
Branch to LABEL if( !(REG1 & ( 1 <<  (OP(31) & 0x1f) )) )
```

Example:

```
qbbc     myLabel r3, r1     // Branch if( !(r3&(1<<r1)) )
qbbc     myLabel, r1.b1, 5  // Branch if( !(r1.b1 & 1<<5) )
```

Format 2:

Definition:

```
QBBC LABEL, Rn.tx
```

Operation:

```
Branch to LABEL if( !(Rn & Rn.tx) )
```

Copyright © 2011, Texas Instruments Incorporated

Example:

```
qbbc     myLabel, r1.b1.t5    // Branch if( !(r1.b1 & 1<<5) )
qbbc     myLabel, r0.t0    // Brach if bit 0 in R0 is clear
```

4.5.3.4.3.14 Wait Until Bit Set (WBS)

The WBS instruction is a pseudo op that uses the QBBC instruction. It is used to poll on a status bit, spinning until the bit is set. In this case, REG1 is almost certainly R31, else this instruction could lead to an infinite loop.

Format 1:

Definition:

```
WBS REG1, OP(255)
```

Operation:

```
QBBC $, REG1, OP(255)
```

Example:

```
wbs     r31, r1         // Spin here while ( !(r31&(1<<r1)) )
wbs     r31.b1, 5      // Spin here while ( !(r31.b1 & 1<<5) )
```

Format 2:

Definition:

```
WBS Rn.tx
```

Operation:

```
QBBC $, Rn.tx
```

Example:

```
wbs     r31.b1.t5     // Spin here while ( !(r31.b1 & 1<<5) )
wbs     r31.t0        // Spin here while bit 0 in R31 is clear
```

4.5.3.4.3.15 Wait Until Bit Clear (WBC)

The WBC instruction is a pseudo op that uses the QBBS instruction. It is used to poll on a status bit, spinning until the bit is clear. In this case, REG1 is almost certainly R31, else this instruction could lead to an infinite loop.

Format 1:

Definition:

```
WBC REG1, OP(255)
```

Operation:

```
QBBS $, REG1, OP(255)
```

Example:

```
wbc     r31, r1         // Spin here while ( r31&(1<<r1) )
wbc     r31.b1, 5      // Spin here while ( r31.b1 & 1<<5 )
```

Format 2:

Definition:

```
WBC Rn.tx
```

Operation:

```
QBBS $, Rn.tx
```

Example:

```
wbc     r31.b1.t5    // Spin here while ( r31.b1 & 1<<5 )
wbc     r31.t0       // Spin here while bit 0 in R31 is set
```

Copyright © 2011, Texas Instruments Incorporated

4.5.3.4.3.16 Halt Operation (HALT)

The HALT instruction disables the PRU. This instruction is used to implement software breakpoints in a debugger. The PRU program counter remains at its current location (the location of the HALT). When the PRU is re-enabled, the instruction is re-fetched from instruction memory.

Definition: HALT

Operation: Disable PRU

Example: halt

4.5.3.4.3.17 Sleep Operation (SLP)

The SLP instruction will sleep the PRU, causing it to disable its clock. This instruction can specify either a permanent sleep (requiring a PRU reset to recover) or a “wake on event”. When the wake on event option is set to “1”, the PRU will wake on any event that is enabled in the PRU Wakeup Enable register.

Definition: SLP IM(1)

Operation: Sleep the PRU with operational "wake on event" flag.

Example:

```
SLP    0    // Sleep without wake events
SLP    1    // Sleep until wake event set
```

Copyright © 2011, Texas Instruments Incorporated

4.5.3.4.3.18 Hardware Loop Assist (LOOP, ILOOP)

Defines a hardware-assisted loop operation. The loop can be non-interruptible (LOOP), or can be interruptible based on an external break signal (ILOOP). The loop operation works by detecting when the instruction pointer would normal hit the instruction at the designated target label, and instead decrementing a loop counter and jumping back to the instruction immediately following the loop instruction.

Definition:

```
LOOP LABEL, OP(256)
    ILOOP LABEL, OP(256)
```

Operation:

```
LoopCounter = OP(256)
                    LoopTop       = $+1
                    While (LoopCounter>0)
    {
                        If (InstructionPointer==LABEL)
        {
            LoopCounter--;
            InstructionPointer = LoopTop;
        }
                    }
```

Example 1:

```
loop    EndLoop, 5        // Peform the loop 5 times
        mvi     r2, *r1.b0        // Get value
        xor     r2, r2, r3        // Change value
        mvi     *r1.b0++, r1      // Save value
    EndLoop:
```

Example 2:

```
mvi     r2, *r1.b0++      // Get the number of elements
        loop    EndLoop, r2       // Peform the loop for each element
        mvi     r2, *r1.b0        // Get value
        call    ProcessValue      // It is legal to jump outside the loop
        mvi     *r1.b0++, r1      // Save value
    EndLoop:
```

Note: When the loop count is set from a register, only the 16 LS bits are used (regardless of the field size). If this 16-bit value is zero, the instruction jumps directly to the end of loop.

4.5.4 PRUSS_PRU_CTRL Registers

Table 4-25 lists the memory-mapped registers for the PRUSS_PRU_CTRL. All register offset addresses not listed in Table 4-25 should be considered as reserved locations and the register contents should not be modified.

Table 4-25. PRUSS_PRU_CTRL REGISTERS

Offset	Acronym	Register Description	Section
0h	CONTROL	CONTROL REGISTER	Section 14.11.3
4h	STATUS	STATUS REGISTER	Section 7.3.5.2
8h	WAKEUP_EN	WAKEUP ENABLE REGISTER	Section 4.5.4.3
Ch	CYCLE	CYCLE COUNT. This register counts the number of cycles for which the PRU has been enabled.	Section 4.5.4.4
10h	STALL	STALL COUNT. This register counts the number of cycles for which the PRU has been enabled, but unable to fetch a new instruction. It is linked to the Cycle Count Register (0x0C) such that this register reflects the stall cycles measured over the same cycles as counted by the cycle count register. Thus the value of this register is always less than or equal to cycle count.	Section 4.5.4.5

Copyright © 2011, Texas Instruments Incorporated

Table 4-25. PRUSS_PRU_CTRL REGISTERS (continued)

Offset	Acronym	Register Description	Section
20h	CTBIR0	CONSTANT TABLE BLOCK INDEX REGISTER 0. This register is used to set the block indices which are used to modify entries 24 and 25 in the PRU Constant Table. This register can be written by the PRU whenever it needs to change to a new base pointer for a block in the State / Scratchpad RAM. This function is useful since the PRU is often processing multiple processing threads which require it to change contexts. The PRU can use this register to avoid requiring excessive amounts of code for repetitive context switching. The format of this register is as follows:	Section 4.5.4.6
24h	CTBIR1	CONSTANT TABLE BLOCK INDEX REGISTER 1. This register is used to set the block indices which are used to modify entries 24 and 25 in the PRU Constant Table. This register can be written by the PRU whenever it needs to change to a new base pointer for a block in the State / Scratchpad RAM. This function is useful since the PRU is often processing multiple processing threads which require it to change contexts. The PRU can use this register to avoid requiring excessive amounts of code for repetitive context switching. The format of this register is as follows:	Section 4.5.4.7
28h	CTPPR0	CONSTANT TABLE PROGRAMMABLE POINTER REGISTER 0. This register allows the PRU to set up the 256-byte page index for entries 28 and 29 in the PRU Constant Table which serve as general purpose pointers which can be configured to point to any locations inside the session router address map. This register is useful when the PRU needs to frequently access certain structures inside the session router address space whose locations are not hard coded such as tables in scratchpad memory. This register is formatted as follows:	Section 4.5.4.8
2Ch	CTPPR1	CONSTANT TABLE PROGRAMMABLE POINTER REGISTER 1. This register functions the same as the PRU Constant Table Programmable Pointer Register 0 but allows the PRU to control entries 30 and 31 in the PRU Constant Table. This register is formatted as follows:	Section 4.5.4.9

Copyright © 2011, Texas Instruments Incorporated

4.5.4.1 CONTROL Register (offset = 0h) [reset = 1h]

CONTROL REGISTER

CONTROL is shown in Figure 14-201 and described in Table 14-215.

Figure 4-18. CONTROL Register

31	30	29	28	27	26	25	24
PCOUNTER_RST_VAL							
R/W-0h							

23	22	21	20	19	18	17	16
PCOUNTER_RST_VAL							
R/W-0h							

15	14	13	12	11	10	9	8
RUNSTATE	Reserved	Reserved					SINGLE_STEP
R-0h	R-0h						R/W-0h

7	6	5	4	3	2	1	0
Reserved				COUNTER_ENABLE	SLEEPING	ENABLE	SOFT_RST_N
				R/W-0h	R/W-0h	R/W-0h	R-1h

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

Table 4-26. CONTROL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	PCOUNTER_RST_VAL	R/W	0h	Program Counter Reset Value: This field controls the address where the PRU will start executing code from after it is taken out of reset.
15	RUNSTATE	R	0h	Run State: This bit indicates whether the PRU is currently executing an instruction or is halted. 0 = PRU is halted and host has access to the instruction RAM and debug registers regions. 1 = PRU is currently running and the host is locked out of the instruction RAM and debug registers regions. This bit is used by an external debug agent to know when the PRU has actually halted when waiting for a HALT instruction to execute, a single step to finish, or any other time when the pru_enable has been cleared.
14	Reserved	R	0h	
8	SINGLE_STEP	R/W	0h	Single Step Enable: This bit controls whether or not the PRU will only execute a single instruction when enabled. 0 = PRU will free run when enabled. 1 = PRU will execute a single instruction and then the pru_enable bit will be cleared. Note that this bit does not actually enable the PRU, it only sets the policy for how much code will be run after the PRU is enabled. The pru_enable bit must be explicitly asserted. It is legal to initialize both the single_step and pru_enable bits simultaneously. (Two independent writes are not required to cause the stated functionality.)
3	COUNTER_ENABLE	R/W	0h	PRU Cycle Counter Enable: Enables PRU cycle counters. 0 = Counters not enabled 1 = Counters enabled
2	SLEEPING	R/W	0h	PRU Sleep Indicator: This bit indicates whether or not the PRU is currently asleep. 0 = PRU is not asleep 1 = PRU is asleep If this bit is written to a 0, the PRU will be forced to power up from sleep mode.

Copyright © 2011, Texas Instruments Incorporated

Table 4-26. CONTROL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	ENABLE	R/W	0h	Processor Enable: This bit controls whether or not the PRU is allowed to fetch new instructions. 0 = PRU is disabled. 1 = PRU is enabled. If this bit is de-asserted while the PRU is currently running and has completed the initial cycle of a multi-cycle instruction (LBxO,SBxO,SCAN, etc.), the current instruction will be allowed to complete before the PRU pauses execution. Otherwise, the PRU will halt immediately. Because of the unpredictability/timing sensitivity of the instruction execution loop, this bit is not a reliable indication of whether or not the PRU is currently running. The pru_state bit should be consulted for an absolute indication of the run state of the core. When the PRU is halted, its internal state remains coherent therefore this bit can be reasserted without issuing a software reset and the PRU will resume processing exactly where it left off in the instruction stream.
0	SOFT_RST_N	R	1h	Soft Reset: When this bit is cleared, the PRU will be reset. This bit is set back to 1 on the next cycle after it has been cleared.

Copyright © 2011, Texas Instruments Incorporated

4.5.4.2 STATUS Register (offset = 4h) [reset = 0h]

STATUS REGISTER

STATUS is shown in Figure 7-92 and described in Table 7-112.

Figure 4-19. STATUS Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																PCOUNTER															
R-0h																R-0h															

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 4-27. STATUS Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	PCOUNTER	R	0h	Program Counter: This field is a registered (1 cycle delayed) reflection of the PRU program counter. Note that the PC is an instruction address where each instruction is a 32 bit word. This is not a byte address and to compute the byte address just multiply the PC by 4 (PC of 2 = byte address of 0x8, or PC of 8 = byte address of 0x20).

Copyright © 2011, Texas Instruments Incorporated

4.5.4.3 WAKEUP_EN Register (offset = 8h) [reset = 0h]

WAKEUP ENABLE REGISTER

WAKEUP_EN is shown in Figure 4-20 and described in Table 4-28.

Figure 4-20. WAKEUP_EN Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BITWISE_ENABLES																															
R/W-0h																															

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 4-28. WAKEUP_EN Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	BITWISE_ENABLES	R/W	0h	Wakeup Enables: This field is ANDed with the incoming R31 status inputs (whose bit positions were specified in the stmap parameter) to produce a vector which is unary ORed to produce the status_wakeup source for the core. Setting any bit in this vector will allow the corresponding status input to wake up the core when it is asserted high. The PRU should set this enable vector prior to executing a SLP (sleep) instruction to ensure that the desired sources can wake up the core.

Copyright © 2011, Texas Instruments Incorporated

4.5.4.4 CYCLE Register (offset = Ch) [reset = 0h]

CYCLE COUNT. This register counts the number of cycles for which the PRU has been enabled.

CYCLE is shown in Figure 4-21 and described in Table 4-29.

Figure 4-21. CYCLE Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CYCLECOUNT																															
-0h																															

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 4-29. CYCLE Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	CYCLECOUNT		0h	This value is incremented by 1 for every cycle during which the PRU is enabled and the counter is enabled (both bits ENABLE and COUNTENABLE set in the PRU control register). Counting halts while the PRU is disabled or counter is disabled, and resumes when re-eneabled. Counter clears the COUNTENABLE bit in the PRU control register when the count reaches 0xFFFFFFFF. (Count does does not wrap). The register can be read at any time. The register can be cleared when the counter or PRU is disabled. Clearing this register also clears the PRU Stall Count Register.

Copyright © 2011, Texas Instruments Incorporated

4.5.4.5 STALL Register (offset = 10h) [reset = 0h]

STALL COUNT. This register counts the number of cycles for which the PRU has been enabled, but unable to fetch a new instruction. It is linked to the Cycle Count Register (0x0C) such that this register reflects the stall cycles measured over the same cycles as counted by the cycle count register. Thus the value of this register is always less than or equal to cycle count.

STALL is shown in Figure 4-22 and described in Table 4-30.

Figure 4-22. STALL Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
STALLCOUNT																															
-0h																															

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 4-30. STALL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	STALLCOUNT		0h	This value is incremented by 1 for every cycle during which the PRU is enabled and the counter is enabled (both bits ENABLE and COUNTENABLE set in the PRU control register), and the PRU was unable to fetch a new instruction for any reason.

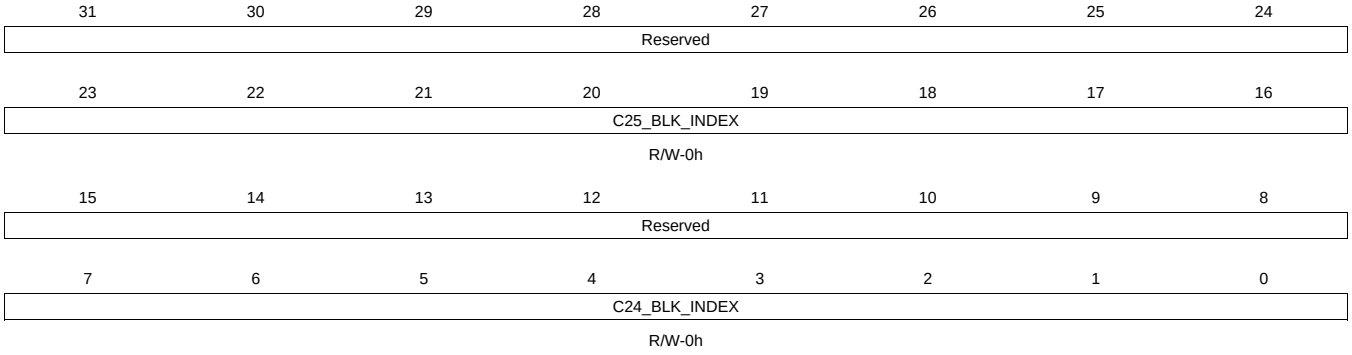
Copyright © 2011, Texas Instruments Incorporated

4.5.4.6 CTBIR0 Register (offset = 20h) [reset = 0h]

CONSTANT TABLE BLOCK INDEX REGISTER 0. This register is used to set the block indices which are used to modify entries 24 and 25 in the PRU Constant Table. This register can be written by the PRU whenever it needs to change to a new base pointer for a block in the State / Scratchpad RAM. This function is useful since the PRU is often processing multiple processing threads which require it to change contexts. The PRU can use this register to avoid requiring excessive amounts of code for repetitive context switching. The format of this register is as follows:

CTBIR0 is shown in Figure 4-23 and described in Table 4-31.

Figure 4-23. CTBIR0 Register



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

Table 4-31. CTBIR0 Register Field Descriptions

Bit	Field	Type	Reset	Description
23-16	C25_BLK_INDEX	R/W	0h	PRU Constant Entry 25 Block Index: This field sets the value that will appear in bits 11:8 of entry 25 in the PRU Constant Table.
7-0	C24_BLK_INDEX	R/W	0h	PRU Constant Entry 24 Block Index: This field sets the value that will appear in bits 11:8 of entry 24 in the PRU Constant Table.

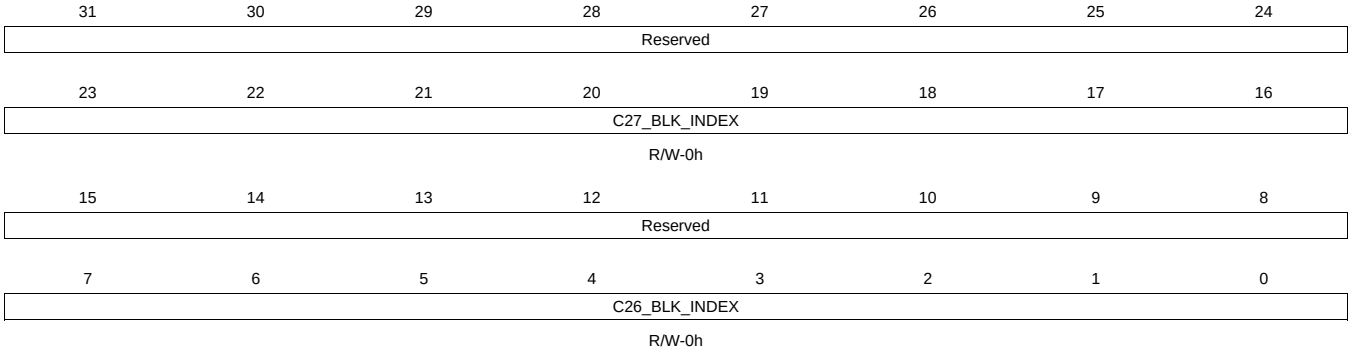
4.5.4.7 CTBIR1 Register (offset = 24h) [reset = 0h]

CONSTANT TABLE BLOCK INDEX REGISTER 1. This register is used to set the block indices which are used to modify entries 24 and 25 in the PRU Constant Table. This register can be written by the PRU whenever it needs to change to a new base pointer for a block in the State / Scratchpad RAM. This function is useful since the PRU is often processing multiple processing threads which require it to change contexts. The PRU can use this register to avoid requiring excessive amounts of code for repetitive context switching. The format of this register is as follows:

CTBIR1 is shown in Figure 4-24 and described in Table 4-32.

Figure 4-24. CTBIR1 Register



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

Table 4-32. CTBIR1 Register Field Descriptions

Bit	Field	Type	Reset	Description
23-16	C27_BLK_INDEX	R/W	0h	PRU Constant Entry 27 Block Index: This field sets the value that will appear in bits 11:8 of entry 27 in the PRU Constant Table.
7-0	C26_BLK_INDEX	R/W	0h	PRU Constant Entry 26 Block Index: This field sets the value that will appear in bits 11:8 of entry 26 in the PRU Constant Table.

4.5.4.8 CTPPR0 Register (offset = 28h) [reset = 0h]

CONSTANT TABLE PROGRAMMABLE POINTER REGISTER 0. This register allows the PRU to set up the 256-byte page index for entries 28 and 29 in the PRU Constant Table which serve as general purpose pointers which can be configured to point to any locations inside the session router address map. This register is useful when the PRU needs to frequently access certain structures inside the session router address space whose locations are not hard coded such as tables in scratchpad memory. This register is formatted as follows:

CTPPR0 is shown in Figure 4-25 and described in Table 4-33.

Figure 4-25. CTPPR0 Register

4.5.4.9 CTPPR1 Register (offset = 2Ch) [reset = 0h]

CONSTANT TABLE PROGRAMMABLE POINTER REGISTER 1. This register functions the same as the PRU Constant Table Programmable Pointer Register 0 but allows the PRU to control entries 30 and 31 in the PRU Constant Table. This register is formatted as follows:

CTPPR1 is shown in Figure 4-26 and described in Table 4-34.

Figure 4-26. CTPPR1 Register

Table 4-34. CTPPR1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	C31_POINTER	R/W	0h	PRU Constant Entry 31 Pointer: This field sets the value that will appear in bits 23:8 of entry 31 in the PRU Constant Table.
15-0	C30_POINTER	R/W	0h	PRU Constant Entry 30 Pointer: This field sets the value that will appear in bits 23:8 of entry 30 in the PRU Constant Table.

4.5.5 PRUSS_PRU_DEBUG Registers

Table 4-35 lists the memory-mapped registers for the PRUSS_PRU_DEBUG. All register offset addresses not listed in Table 4-35 should be considered as reserved locations and the register contents should not be modified.

Table 4-35. PRUSS_PRU_DEBUG REGISTERS

Offset	Acronym	Register Description	Section
0h	GPREG0	DEBUG PRU GENERAL PURPOSE REGISTER 0. This register allows an external agent to debug the PRU while it is disabled. Reading or writing to these registers will have the same effect as a read or write to these registers from an internal instruction in the PRU. For R30, this includes generation of the pulse outputs whenever the register is written.	Section 4.5.5.1
4h	GPREG1	DEBUG PRU GENERAL PURPOSE REGISTER 1. This register allows an external agent to debug the PRU while it is disabled. Reading or writing to these registers will have the same effect as a read or write to these registers from an internal instruction in the PRU. For R30, this includes generation of the pulse outputs whenever the register is written.	Section 4.5.5.2
8h	GPREG2	DEBUG PRU GENERAL PURPOSE REGISTER 2. This register allows an external agent to debug the PRU while it is disabled. Reading or writing to these registers will have the same effect as a read or write to these registers from an internal instruction in the PRU. For R30, this includes generation of the pulse outputs whenever the register is written.	Section 4.5.5.3

4.6 Interrupt Controller

4.6.1 Introduction

The PRUSS interrupt controller (INTC) is an interface between interrupts coming from different parts of the system (referred to as system events) and the PRUSS interrupt interface.

The PRUSS INTC has the following features:

- Capturing up to 64 System Events
- Supports up to 10 interrupt channels.
- Generation of 10 Host Interrupts
  - 2 Host Interrupts for the PRUs.
  - 8 Host Interrupts exported from the PRUSS for signaling the ARM interrupt controllers.
- Each system event can be enabled and disabled.
- Each host event can be enabled and disabled.
- Hardware prioritization of events.

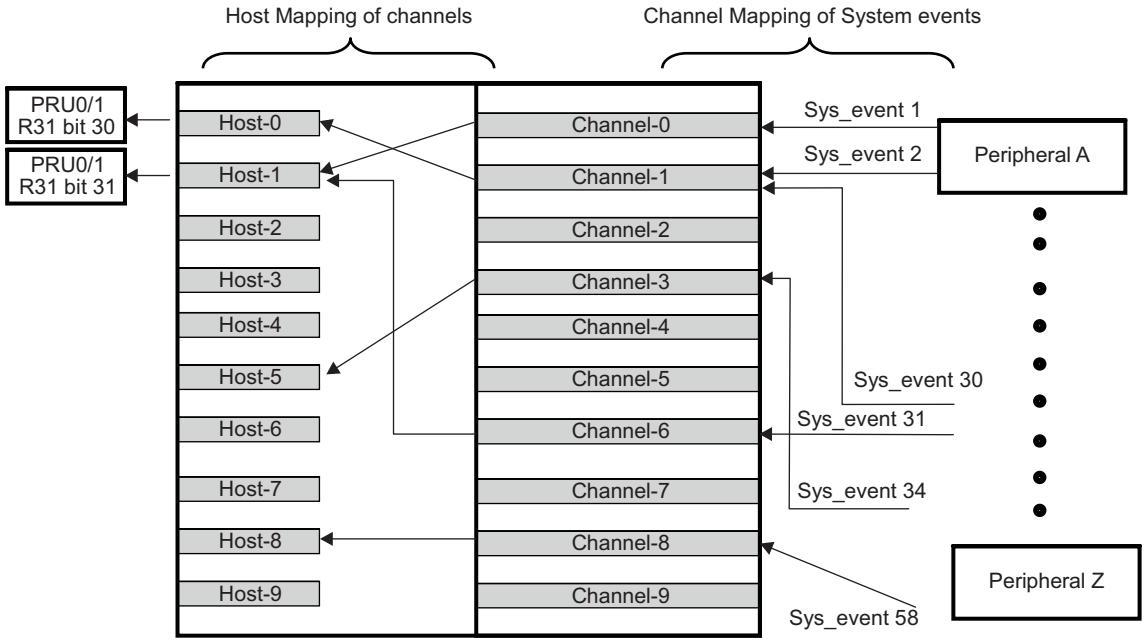
Copyright © 2011, Texas Instruments Incorporated

4.6.2 Functional Description

The PRUSS INTC supports up to 64 system interrupts from different peripherals and PRUs to be mapped to 10 channels inside the INTC (see Figure 4-91). Interrupts from these 10 channels are further mapped to 10 Host Interrupts.

- Any of the 64 system interrupts can be mapped to any of the 10 channels.
- Multiple interrupts can be mapped to a single channel.
- An interrupt should not be mapped to more than one channel.
- Any of the 10 channels can be mapped to any of the 10 host interrupts. It is recommended to map channel “x” to host interrupt “x”, where x is from 0 to 9
- A channel should not be mapped to more than one host interrupt
- For channels mapping to the same host interrupt, lower number channels have higher priority.
- For interrupts on same channel, priority is determined by the hardware interrupt number. The lower the interrupt number, the higher the priority.
- Host Interrupt 0 is connected to bit 30 in register 31 of PRU0 and PRU1.
- Host Interrupt 1 is connected to bit 31 in register 31 for PRU0 and PRU1.
- Host Interrupts 2 through 9 exported from PRUSS for signaling ARM interrupt controllers or other machines like EDMA.

Figure 4-91. Interrupt Controller Block Diagram



4.6.2.1 PRUSS System Events

The PRUSS system events can be found in the interrupt section of TRM. The device includes a internal mux that selects the Non Ethercat (default) or Ethercat mode system events. The mux control signal is controlled by MIIRTEEN [MII_RT_EVENT_EN], which can be modified by software in PRUSS CFG register space.

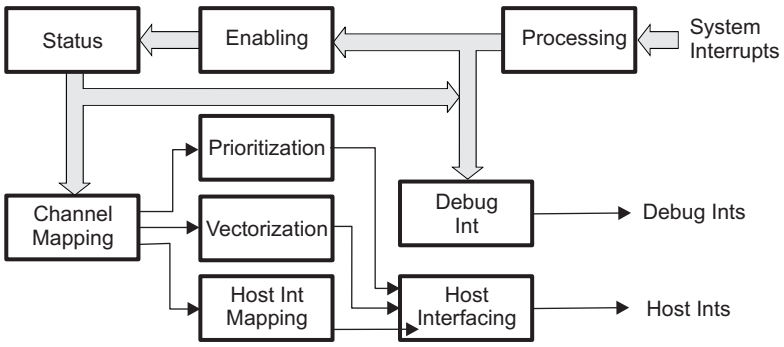
4.6.2.2 INTC Methodology

The INTC module controls the system event mapping to the host interrupt interface. System events are generated by the device peripherals or PRUs. The INTC receives the system interrupts and maps them to internal channels. The channels are used to group interrupts together and to prioritize them. These channels are then mapped onto the host interrupts. Interrupts from the system side are active high in polarity. They are also pulse type of interrupts.

Copyright © 2011, Texas Instruments Incorporated

The INTC encompasses many functions to process the system interrupts and prepare them for the host interface. These functions are: processing, enabling, status, channel mapping, host interrupt mapping, prioritization, and host interfacing. Figure 4-92 illustrates the flow of system interrupts through the functions to the host. The following subsections describe each part of the flow.

Figure 4-92. Flow of System Interrupts to Host



4.6.2.2.1 Interrupt Processing

This block does following tasks:

- Synchronization of slower and asynchronous interrupts
- Conversion of polarity to active high
- Conversion of interrupt type to pulse interrupts

After the processing block, all interrupts will be active high pulses.

4.6.2.2.1.1 Interrupt Enabling

The next stage of INTC is to enable system interrupts based on programmed settings. The following sequence is to be followed to enable interrupts:

- Enable all host interrupts: By setting the ENABLE bit in the global enable register (GER) to 1, all host interrupts will be enabled. Individual host interrupts are still enabled or disabled from their individual enables and are not overridden by the global enable.
- Enable required host interrupts: By writing 1 to the appropriate bit of the INDEX field in the host interrupt enable indexed set register (HIEISR), enable the required host interrupts. The host interrupt to enable is the index value written. This enables the host interrupt output or triggers the output again if that host interrupt is already enabled.
- Enable required system interrupts: System interrupts that are required to get propagated to host are to be enabled individually by writing to INDEX field in the system interrupt enable indexed set register (EISR). The interrupt to enable is the index value written. This sets the Enable Register bit of the given index.

4.6.2.2.2 Interrupt Status Checking

The next stage is to capture which system interrupts are pending. There are two kinds of pending status: raw status and enabled status. Raw status is the pending status of the system interrupt without regards to the enable bit for the system interrupt. Enabled status is the pending status of the system interrupts with the enable bits active. When the enable bit is inactive, the enabled status will always be inactive. The enabled status of system interrupts is captured in system interrupt status enabled/clear registers (SECR1-SECR2).

Status of system interrupt 'N' is indicated by the Nth bit of SECR1-SECR2. Since there are 64 system interrupts, two 32-bit registers are used to capture the enabled status of interrupts. The pending status reflects whether the system interrupt occurred since the last time the status register bit was cleared. Each bit in the status register can be individually cleared.

4.6.2.2.3 Interrupt Channel Mapping

The INTC has 10 internal channels to which enabled system interrupts can be mapped. Channel 0 has highest priority and channel 9 has the lowest priority. Channels are used to group the system interrupts into a smaller number of priorities that can be given to a host interface with a very small number of interrupt inputs.

When multiple system interrupts are mapped to the same channel their interrupts are ORed together so that when either is active the output is active. The channel map registers (CMRm) define the channel for each system interrupt. There is one register per 4 system interrupts; therefore, there are16 channel map registers for a system of 64 interrupts. The channel for each system interrupt can be set using these registers.

4.6.2.2.3.1 Host Interrupt Mapping

The hosts can be the PRUs or ARM CPU. The 10 channels from the INTC can mapped to any of the 10 Host interrupts. The Host map registers (HMR*m*) define the channel for each system interrupt. There is one register per 4 channels; therefore, there are 3 host map registers for 10 channels. When multiple channels are mapped to the same host interrupt, then prioritization is done to select which interrupt is in the highest-priority channel and which should be sent first to the host.

4.6.2.2.3.2 Interrupt Prioritization

The next stage of the INTC is prioritization. Since multiple interrupts can feed into a single channel and multiple channels can feed into a single host interrupt, it is to read the status of all system interrupts to determine the highest priority interrupt that is pending. The INTC provides hardware to perform this prioritization with a given scheme so that software does not have to do this. There are two levels of prioritizations:

- The first level of prioritization is between the active channels for a host interrupt. Channel 0 has the highest priority and channel 9 has the lowest. So the first level of prioritization picks the lowest numbered active channel.
- The second level of prioritization is between the active system interrupts for the prioritized channel. The system interrupt in position 0 has the highest priority and system interrupt 63 has the lowest priority. So the second level of prioritization picks the lowest position active system interrupt.

This is the final prioritized system interrupt for the host interrupt and is stored in the global prioritized index register (GPIR). The highest priority pending interrupt with respect to each host interrupts can be obtained using the host interrupt prioritized index registers (HIPIRn).

4.6.2.2.4 Interrupt Nesting

The INTC can also perform a nesting function in its prioritization. Nesting is a method of disabling certain interrupts (usually lower-priority interrupts) when an interrupt is taken so that only those desired interrupts can trigger to the host while it is servicing the current interrupt. The typical usage is to nest on the current interrupt and disable all interrupts of the same or lower priority (or channel). Then the host will only be interrupted from a higher priority interrupt.

The nesting is done in one of three methods:

1. Nesting for all host interrupts, based on channel priority: When an interrupt is taken, the nesting level is set to its channel priority. From then, that channel priority and all lower priority channels will be disabled from generating host interrupts and only higher priority channels are allowed. When the interrupt is completely serviced, the nesting level is returned to its original value. When there is no interrupt being serviced, there are no channels disabled due to nesting. The global nesting level register (GNLR) allows the checking and setting of the global nesting level across all host interrupts. The nesting level is the channel (and all of lower priority channels) that are nested out because of a current interrupt.
2. Nesting for individual host interrupts, based on channel priority: Always nest based on channel priority for each host interrupt individually. When an interrupt is taken on a host interrupt, then, the nesting level is set to its channel priority for just that host interrupt, and other host interrupts do not have their nesting affected. Then for that host interrupt, equal or lower priority channels will not interrupt the host but may on other host interrupts if programmed. When the interrupt is completely serviced the nesting

Copyright © 2011, Texas Instruments Incorporated

level for the host interrupt is returned to its original value. The host interrupt nesting level registers (HINLR1 and HINLR2) display and control the nesting level for each host interrupt. The nesting level controls which channel and lower priority channels are nested. There is one register per host interrupt.

3. Software manually performs the nesting of interrupts. When an interrupt is taken, the software will disable all the host interrupts, manually update the enables for any or all the system interrupts, and then re-enables all the host interrupts. This now allows only the system interrupts that are still enabled to trigger to the host. When the interrupt is completely serviced the software must reverse the changes to re-enable the nested out system interrupts. This method requires the most software interaction but gives the most flexibility if simple channel based nesting mechanisms are not adequate.

4.6.2.2.5 Interrupt Status Clearing

After servicing the interrupt (after execution of the ISR), interrupt status is to be cleared. If a system interrupt status is not cleared, then another host interrupt may not be triggered or another host interrupt may be triggered incorrectly. It is also essential to clear all system interrupts before the PRU is halted as the PRU does not power down unless all the interrupt status are cleared. For clearing the status of an interrupt, whose interrupt number is N, write a 1 to the Nth bit position in the system interrupt status enabled/clear registers (SECR1-SECR2). System interrupt N can also be cleared by writing the value N into the system interrupt status indexed clear register (SICR).

4.6.2.3 Interrupt Disabling

At any time, if any interrupt is not to be propagated to the host, then that interrupt should be disabled. For disabling an interrupt whose interrupt number is N, write a 1 to the Nth bit in the system interrupt enable clear registers (ECR1-ECR2). System interrupt N can also be disabled by writing the value N in the system interrupt enable indexed clear register (EICR).

4.6.3 Basic Programming Model

Follow these steps to configure the interrupt controller.

1. Set polarity and type of system event through the System Interrupt Polarity Registers (SIPR1 and SPIR2) and the System Interrupt Type Registers (SITR1 and SITR2). Polarity of all system interrupts is always high. Type of all system interrupts is always pulse.
2. Map system event to INTC channel through CHANMAP registers.
3. Map channel to host interrupt through HOSTMAP registers. Recommend channel “x” be mapped to host interrupt “x”.
4. Clear system interrupt by writing 1s to SECR registers.
5. Enable host interrupt by writing index value to HOSTINTENIDX register.
6. Enable interrupt nesting if desired.
7. Globally enable all interrupts through GLBLEN register.

4.6.4 PRUSS_INTC Registers

Table 4-100 lists the memory-mapped registers for the PRUSS_INTC. All register offset addresses not listed in Table 4-100 should be considered as reserved locations and the register contents should not be modified.

Table 4-100. PRUSS_INTC REGISTERS

Offset	Acronym	Register Description	Section
0h	REVID	Revision ID Register	Section 15.4.3.25
4h	CR	The Control Register holds global control parameters and can forces a soft reset on the module.	Section 4.6.4.2
10h	GER	The Global Host Interrupt Enable Register enables all the host interrupts. Individual host interrupts are still enabled or disabled from their individual enables and are not overridden by the global enable.	Section 4.6.4.3

Table 4-100. PRUSS_INTC REGISTERS (continued)

Offset	Acronym	Register Description	Section
1Ch	GNLR	The Global Nesting Level Register allows the checking and setting of the global nesting level across all host interrupts when automatic global nesting mode is set. The nesting level is the channel (and all of lower priority) that are nested out because of a current interrupt. This register is only available when nesting is configured.	Section 4.6.4.4
20h	SISR	The System Interrupt Status Indexed Set Register allows setting the status of an interrupt. The interrupt to set is the index value written. This sets the Raw Status Register bit of the given index.	Section 4.6.4.5
24h	SICR	The System Interrupt Status Indexed Clear Register allows clearing the status of an interrupt. The interrupt to clear is the index value written. This clears the Raw Status Register bit of the given index.	Section 4.6.4.6
28h	EISR	The System Interrupt Enable Indexed Set Register allows enabling an interrupt. The interrupt to enable is the index value written. This sets the Enable Register bit of the given index.	Section 4.6.4.7
2Ch	EICR	The System Interrupt Enable Indexed Clear Register allows disabling an interrupt. The interrupt to disable is the index value written. This clears the Enable Register bit of the given index.	Section 4.6.4.8
34h	HIEISR	The Host Interrupt Enable Indexed Set Register allows enabling a host interrupt output. The host interrupt to enable is the index value written. This enables the host interrupt output or triggers the output again if already enabled.	Section 4.6.4.9
38h	HIDISR	The Host Interrupt Enable Indexed Clear Register allows disabling a host interrupt output. The host interrupt to disable is the index value written. This disables the host interrupt output.	Section 4.6.4.10
80h	GPIR	The Global Prioritized Index Register shows the interrupt number of the highest priority interrupt pending across all the host interrupts.	Section 4.6.4.11
200h	SRSR0	The System Interrupt Status Raw/Set Register0 show the pending enabled status of the system interrupts 0 to 31. Software can write to the Status Set Registers to set a system interrupt without a hardware trigger. There is one bit per system interrupt.	Section 4.6.4.12
204h	SRSR1	The System Interrupt Status Raw/Set Register1 show the pending enabled status of the system interrupts 32 to 63. Software can write to the Status Set Registers to set a system interrupt without a hardware trigger. There is one bit per system interrupt.	Section 4.6.4.13
280h	SECR0	The System Interrupt Status Enabled/Clear Register0 show the pending enabled status of the system interrupts 0 to 31. Software can write to the Status Clear Registers to clear a system interrupt after it has been serviced. If a system interrupt status is not cleared then another host interrupt may not be triggered or another host interrupt may be triggered incorrectly. There is one bit per system interrupt.	Section 4.6.4.14
284h	SECR1	The System Interrupt Status Enabled/Clear Register1 show the pending enabled status of the system interrupts 32 to 63. Software can write to the Status Clear Registers to clear a system interrupt after it has been serviced. If a system interrupt status is not cleared then another host interrupt may not be triggered or another host interrupt may be triggered incorrectly. There is one bit per system interrupt. 4.6.4.4 GNLR Register (offset = 1Ch) [reset = 100h]

The Global Nesting Level Register allows the checking and setting of the global nesting level across all host interrupts when automatic global nesting mode is set. The nesting level is the channel (and all of lower priority) that are nested out because of a current interrupt. This register is only available when nesting is configured.

GNLR is shown in Figure 4-96 and described in Table 4-104.

4.6.4.7 EISR Register (offset = 28h) [reset = 0h]

The System Interrupt Enable Indexed Set Register allows enabling an interrupt. The interrupt to enable is the index value written. This sets the Enable Register bit of the given index.

EISR is shown in Figure 4-99 and described in Table 4-107.

Figure 4-99. EISR Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

4.6.4.8 EICR Register (offset = 2Ch) [reset = 0h]

The System Interrupt Enable Indexed Clear Register allows disabling an interrupt. The interrupt to disable is the index value written. This clears the Enable Register bit of the given index.

EICR is shown in Figure 4-100 and described in Table 4-108.

Figure 4-100. EICR Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

4.6.4.9 HIEISR Register (offset = 34h) [reset = 0h]

The Host Interrupt Enable Indexed Set Register allows enabling a host interrupt output. The host interrupt to enable is the index value written. This enables the host interrupt output or triggers the output again if already enabled.

HIEISR is shown in Figure 4-101 and described in Table 4-109.

Figure 4-101. HIEISR Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

4.6.4.14 SECR0 Register (offset = 280h) [reset = 0h]

The System Interrupt Status Enabled/Clear Register0 show the pending enabled status of the system interrupts 0 to 31. Software can write to the Status Clear Registers to clear a system interrupt after it has been serviced. If a system interrupt status is not cleared then another host interrupt may not be triggered or another host interrupt may be triggered incorrectly. There is one bit per system interrupt.

SECR0 is shown in Figure 4-106 and described in Table 4-114.

Figure 4-106. SECR0 Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

4.7 Universal Asynchronous Receiver/Transmitter

4.7.1 Introduction

4.7.1.1 Purpose of the Peripheral

The UART peripheral is based on the industry standard TL16C550 asynchronous communications element, which in turn is a functional upgrade of the TL16C450. Functionally similar to the TL16C450 on power up (single character or TL16C450 mode), the UART can be placed in an alternate FIFO (TL16C550) mode. This relieves the CPU of excessive software overhead by buffering received and transmitted characters. The receiver and transmitter FIFOs store up to 16 bytes including three additional bits of error status per byte for the receiver FIFO.

The UART performs serial-to-parallel conversions on data received from a peripheral device and parallel-to-serial conversion on data received from the CPU. The CPU can read the UART status at any time. The UART includes control capability and a processor interrupt system that can be tailored to minimize software management of the communications link.

The UART includes a programmable baud generator capable of dividing the UART input clock by divisors from 1 to 65535 and producing a 16× reference clock or a 13× reference clock for the internal transmitter and receiver logic. For detailed timing and electrical specifications for the UART, see your device-specific data manual.

4.7.1.2 Features

Check your device-specific data manual to see the list of features that are supported and that are not supported by the UART.

4.7.1.3 Functional Block Diagram

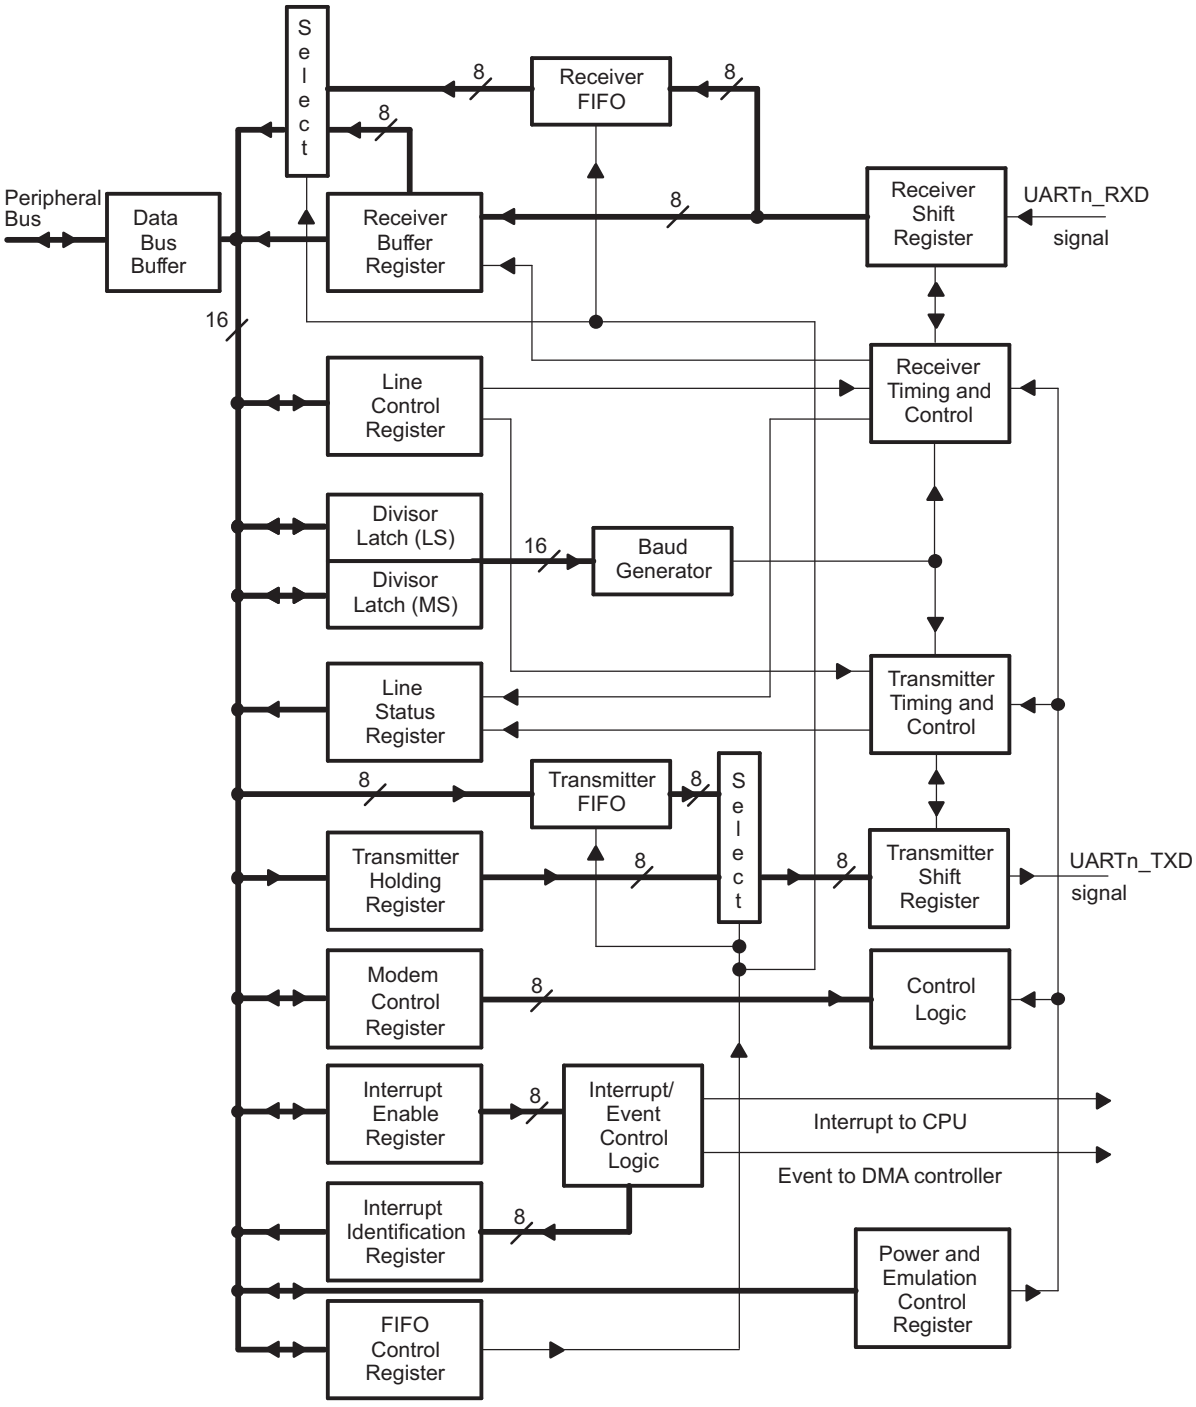
A functional block diagram of the UART is shown in Figure 4-156.

4.7.1.4 Industry Standard(s) Compliance Statement

The UART peripheral is based on the industry standard TL16C550 asynchronous communications element, which is a functional upgrade of the TL16C450. The information in this chapter assumes you are familiar with these standards.

Copyright © 2011, Texas Instruments Incorporated

Figure 4-156. UART Block Diagram



NOTE: The value *n* indicates the applicable UART where there are multiple instances. For the PRUSS, there is only one instance and all UART signals should reflect this (e.g., UART0_TXD instead of UARTn_TXD).

4.7.2 Functional Description

4.7.2.1 Clock Generation and Control

The UART bit clock is derived from an input clock to the UART. See your device-specific data manual to check the maximum data rate supported by the UART.

Figure 4-157 is a conceptual clock generation diagram for the UART. The processor clock generator receives a signal from an external clock source and produces a UART input clock with a programmed frequency. The UART contains a programmable baud generator that takes an input clock and divides it by a divisor in the range between 1 and (2^{16} - 1) to produce a baud clock (BCLK). The frequency of BCLK is sixteen times (16×) the baud rate (each received or transmitted bit lasts 16 BCLK cycles) or thirteen times (13×) the baud rate (each received or transmitted bit lasts 13 BCLK cycles). When the UART is receiving, the bit is sampled in the 8th BCLK cycle for 16× over sampling mode and on the 6th BCLK cycle for 13× over-sampling mode. The 16× or 13× reference clock is selected by configuring the OSM_SEL bit in the mode definition register (MDR). The formula to calculate the divisor is:

$$\text{Divisor} = \frac{\text{UART input clock frequency}}{\text{Desired baud rate} \times 16} \quad [\text{MDR.OSM_SEL} = 0]$$

$$\text{Divisor} = \frac{\text{UART input clock frequency}}{\text{Desired baud rate} \times 13} \quad [\text{MDR.OSM_SEL} = 1]$$

Two 8-bit register fields (DLH and DLL), called divisor latches, hold this 16-bit divisor. DLH holds the most significant bits of the divisor, and DLL holds the least significant bits of the divisor. For information about these register fields, see . These divisor latches must be loaded during initialization of the UART in order to ensure desired operation of the baud generator. Writing to the divisor latches results in two wait states being inserted during the write access while the baud generator is loaded with the new value.

Figure 4-158 summarizes the relationship between the transferred data bit, BCLK, and the UART input clock. Note that the timing relationship depicted in Figure 4-158 shows that each bit lasts for 16 BCLK cycles . This is in case of 16x over-sampling mode. For 13× over-sampling mode each bit lasts for 13 BCLK cycles .

Example baud rates and divisor values relative to a 150-MHz UART input clock and 16× over-sampling mode are shown in Table 4-164.

4.7.2.2 Signal Descriptions

The UARTs utilize a minimal number of signal connections to interface with external devices. The UART signal descriptions are included in Table 4-166. Note that the number of UARTs and their supported features vary on each device, see your device-specific data manual for more details.

Table 4-166. UART Signal Descriptions

Signal Name [1]	Signal Type	Function
UARTn_TXD	Output	Serial data transmit
UARTn_RXD	Input	Serial data receive
$\overline{\text{UARTn_CTS}}$ [2]	Input	Clear-to-Send handshaking signal
$\overline{\text{UARTn_RTS}}$ [2]	Output	Request-to-Send handshaking signal

(1) The value *n* indicates the applicable UART; that is, UART0, UART1, etc.
(2) This signal is not supported in all UARTs. See your device-specific data manual to check if it is supported.

4.7.2.3 Pin Multiplexing

Extensive pin multiplexing is used to accommodate the largest number of peripheral functions in the smallest possible package. Pin multiplexing is controlled using a combination of hardware configuration at device reset and software programmable register settings. See your device-specific data manual to determine how pin multiplexing affects the UART.

4.7.2.4 Protocol Description

4.7.2.4.1 Transmission

The UART transmitter section includes a transmitter hold register (THR) and a transmitter shift register (TSR). When the UART is in the FIFO mode, THR is a 16-byte FIFO. Transmitter section control is a function of the UART line control register (LCR). Based on the settings chosen in LCR, the UART transmitter sends the following to the receiving device:

- 1 START bit
- 5, 6, 7, or 8 data bits
- 1 PARITY bit (optional)
- 1, 1.5, or 2 STOP bits

4.7.2.4.2 Reception

The UART receiver section includes a receiver shift register (RSR) and a receiver buffer register (RBR). When the UART is in the FIFO mode, RBR is a 16-byte FIFO. Receiver section control is a function of the UART line control register (LCR). Based on the settings chosen in LCR, the UART receiver accepts the following from the transmitting device:

- 1 START bit
- 5, 6, 7, or 8 data bits
- 1 PARITY bit (optional)
- 1 STOP bit (any other STOP bits transferred with the above data are not detected)

Copyright © 2011, Texas Instruments Incorporated

4.7.2.4.3 Data Format

The UART transmits in the following format:

1 START bit + data bits (5, 6, 7, 8) + 1 PARITY bit (optional) + STOP bit (1, 1.5, 2)

It transmits 1 START bit; 5, 6, 7, or 8 data bits, depending on the data width selection; 1 PARITY bit, if parity is selected; and 1, 1.5, or 2 STOP bits, depending on the STOP bit selection.

The UART receives in the following format:

1 START bit + data bits (5, 6, 7, 8) + 1 PARITY bit (optional) + 1 STOP bit

It receives 1 START bit; 5, 6, 7, or 8 data bits, depending on the data width selection; 1 PARITY bit, if parity is selected; and 1 STOP bit.

The protocol formats are shown in Figure 4-159.

Figure 4-159. UART Protocol Formats

Transmit/Receive for 5-bit data, parity Enable, 1 STOP bit

		D0	D1	D2	D3	D4	PARITY	STOP1

Transmit/Receive for 6-bit data, parity Enable, 1 STOP bit

		D0	D1	D2	D3	D4	D5	PARITY	STOP1

Transmit/Receive for 7-bit data, parity Enable, 1 STOP bit

		D0	D1	D2	D3	D4	D5	D6	PARITY	STOP1

Transmit/Receive for 8-bit data, parity Enable, 1 STOP bit

		D0	D1	D2	D3	D4	D5	D6	D7	PARITY	STOP1

Copyright © 2011, Texas Instruments Incorporated

4.7.2.5 Operation

4.7.2.5.1 Transmission

The UART transmitter section includes a transmitter hold register (THR) and a transmitter shift register (TSR). When the UART is in the FIFO mode, THR is a 16-byte FIFO. Transmitter section control is a function of the UART line control register (LCR). Based on the settings chosen in LCR, the UART transmitter sends the following to the receiving device:

- 1 START bit
- 5, 6, 7, or 8 data bits
- 1 PARITY bit (optional)
- 1, 1.5, or 2 STOP bits

THR receives data from the internal data bus, and when TSR is ready, the UART moves the data from THR to TSR. The UART serializes the data in TSR and transmits the data on the UARTn_TXD pin.

In the non-FIFO mode, if THR is empty and the THR empty (THRE) interrupt is enabled in the interrupt enable register (IER), an interrupt is generated. This interrupt is cleared when a character is loaded into THR or the interrupt identification register (IIR) is read. In the FIFO mode, the interrupt is generated when the transmitter FIFO is empty, and it is cleared when at least one byte is loaded into the FIFO or IIR is read.

4.7.2.5.2 Reception

The UART receiver section includes a receiver shift register (RSR) and a receiver buffer register (RBR). When the UART is in the FIFO mode, RBR is a 16-byte FIFO. Timing is supplied by the 16× receiver clock. Receiver section control is a function of the UART line control register (LCR). Based on the settings chosen in LCR, the UART receiver accepts the following from the transmitting device:

- 1 START bit
- 5, 6, 7, or 8 data bits
- 1 PARITY bit (optional)
- 1 STOP bit (any other STOP bits transferred with the above data are not detected)

RSR receives the data bits from the UARTn_RXD pin. Then RSR concatenates the data bits and moves the resulting value into RBR (or the receiver FIFO). The UART also stores three bits of error status information next to each received character, to record a parity error, framing error, or break.

In the non-FIFO mode, when a character is placed in RBR and the receiver data-ready interrupt is enabled in the interrupt enable register (IER), an interrupt is generated. This interrupt is cleared when the character is read from RBR. In the FIFO mode, the interrupt is generated when the FIFO is filled to the trigger level selected in the FIFO control register (FCR), and it is cleared when the FIFO contents drop below the trigger level.

Copyright © 2011, Texas Instruments Incorporated

4.7.2.5.3 FIFO Modes

The following two modes can be used for servicing the receiver and transmitter FIFOs:

- FIFO interrupt mode. The FIFO is enabled and the associated interrupts are enabled. Interrupts are sent to the CPU to indicate when specific events occur.
- FIFO poll mode. The FIFO is enabled but the associated interrupts are disabled. The CPU polls status bits to detect specific events.

Because the receiver FIFO and the transmitter FIFO are controlled separately, either one or both can be placed into the interrupt mode or the poll mode.

4.7.2.5.3.1 FIFO Interrupt Mode

When the receiver FIFO is enabled in the FIFO control register (FCR) and the receiver interrupts are enabled in the interrupt enable register (IER), the interrupt mode is selected for the receiver FIFO. The following are important points about the receiver interrupts:

- The receiver data-ready interrupt is issued to the CPU when the FIFO has reached the trigger level that is programmed in FCR. It is cleared when the CPU or the DMA controller reads enough characters from the FIFO such that the FIFO drops below its programmed trigger level.
- The receiver line status interrupt is generated in response to an overrun error, a parity error, a framing error, or a break. This interrupt has higher priority than the receiver data-ready interrupt. For details, see Section 4.7.2.8.
- The data-ready (DR) bit in the line status register (LSR) indicates the presence or absence of characters in the receiver FIFO. The DR bit is set when a character is transferred from the receiver shift register (RSR) to the empty receiver FIFO. The DR bit remains set until the FIFO is empty again.
- A receiver time-out interrupt occurs if all of the following conditions exist:
  - At least one character is in the FIFO,
  - The most recent character was received more than four continuous character times ago. A character time is the time allotted for 1 START bit, *n* data bits, 1 PARITY bit, and 1 STOP bit, where *n* depends on the word length selected with the WLS bits in the line control register (LCR). See Table 4-167.
  - The most recent read of the FIFO has occurred more than four continuous character times before.
- Character times are calculated by using the baud rate.
- When a receiver time-out interrupt has occurred, it is cleared and the time-out timer is cleared when the CPU or the EDMA controller reads one character from the receiver FIFO. The interrupt is also cleared if a new character is received in the FIFO or if the URRST bit is cleared in the power and emulation management register (PWREMU_MGMT).
- If a receiver time-out interrupt has not occurred, the time-out timer is cleared after a new character is received or after the CPU or EDMA reads the receiver FIFO.

When the transmitter FIFO is enabled in FCR and the transmitter holding register empty (THRE) interrupt is enabled in IER, the interrupt mode is selected for the transmitter FIFO. The THRE interrupt occurs when the transmitter FIFO is empty. It is cleared when the transmitter hold register (THR) is loaded (1 to 16 characters may be written to the transmitter FIFO while servicing this interrupt) or the interrupt identification register (IIR) is read.

Table 4-167. Character Time for Word Lengths

Word Length (*n*)	Character Time	Four Character Times
5	Time for 8 bits	Time for 32 bits
6	Time for 9 bits	Time for 36 bits
7	Time for 10 bits	Time for 40 bits
8	Time for 11 bits	Time for 44 bits

Copyright © 2011, Texas Instruments Incorporated

4.7.2.5.3.2 FIFO Poll Mode

When the receiver FIFO is enabled in the FIFO control register (FCR) and the receiver interrupts are disabled in the interrupt enable register (IER), the poll mode is selected for the receiver FIFO. Similarly, when the transmitter FIFO is enabled and the transmitter interrupts are disabled, the transmitted FIFO is in the poll mode. In the poll mode, the CPU detects events by checking bits in the line status register (LSR):

- The RXFIFOE bit indicates whether there are any errors in the receiver FIFO.
- The TEMT bit indicates that both the transmitter holding register (THR) and the transmitter shift register (TSR) are empty.
- The THRE bit indicates when THR is empty.
- The BI (break), FE (framing error), PE (parity error), and OE (overrun error) bits specify which error or errors have occurred.
- The DR (data-ready) bit is set as long as there is at least one byte in the receiver FIFO.

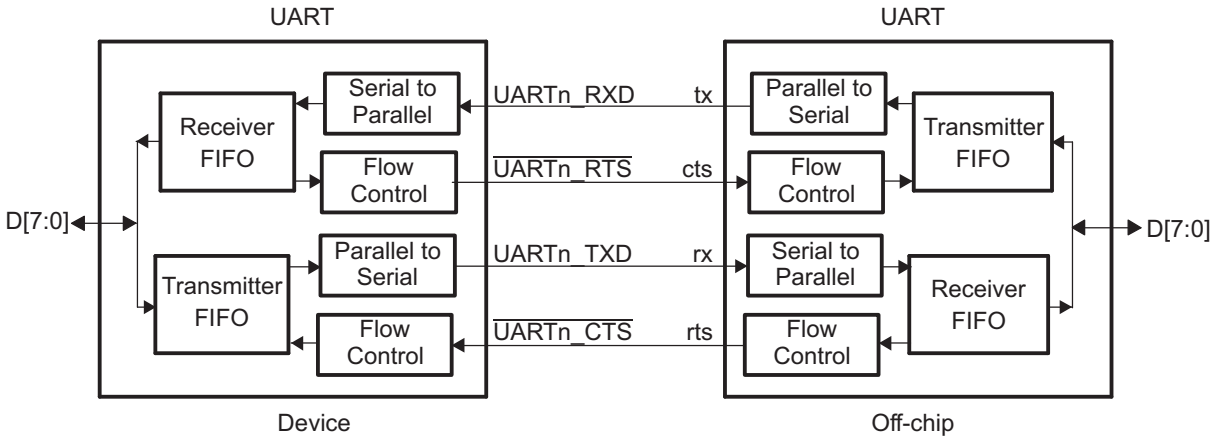
Also, in the FIFO poll mode:

- The interrupt identification register (IIR) is not affected by any events because the interrupts are disabled.
- The UART does not indicate when the receiver FIFO trigger level is reached or when a receiver time-out occurs.

4.7.2.5.4 Autoflow Control

The UART can employ autoflow control by connecting the $\overline{\text{UARTn_CTS}}$ and $\overline{\text{UARTn_RTS}}$ signals. Note that all UARTs do not support autoflow control, see your device-specific data manual for supported features. The $\overline{\text{UARTn_CTS}}$ input must be active before the transmitter FIFO can transmit data. The $\overline{\text{UARTn_RTS}}$ becomes active when the receiver needs more data and notifies the sending device. When $\overline{\text{UARTn_RTS}}$ is connected to $\overline{\text{UARTn_CTS}}$, data transmission does not occur unless the receiver FIFO has space for the data. Therefore, when two UARTs are connected as shown in Figure 4-160 with autoflow enabled, overrun errors are eliminated.

Figure 4-160. UART Interface Using Autoflow Diagram

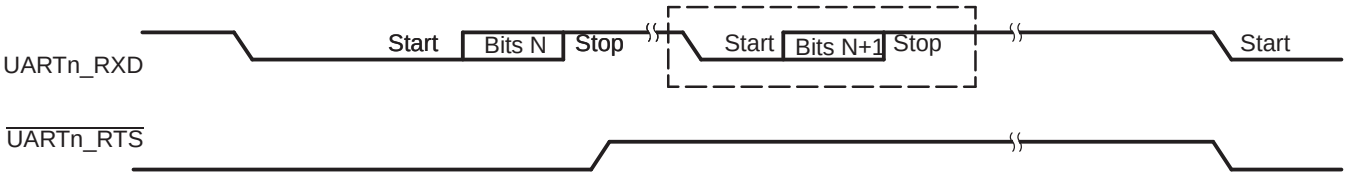


Copyright © 2011, Texas Instruments Incorporated

4.7.2.5.4.1 UARTn_RTS Behavior

UARTn_RTS data flow control originates in the receiver block (see Figure 4-156). When the receiver FIFO level reaches a trigger level of 1, 4, 8, or 14 (see Figure 4-161), UARTn_RTS is deasserted. The sending UART may send an additional byte after the trigger level is reached (assuming the sending UART has another byte to send), because it may not recognize the deassertion of UARTn_RTS until after it has begun sending the additional byte. For trigger level 1, 4, and 8, UARTn_RTS is automatically reasserted once the receiver FIFO is emptied. For trigger level 14, UARTn_RTS is automatically reasserted once the receiver FIFO drops below the trigger level.

Figure 4-161. Autoflow Functional Timing Waveforms for UARTn_RTS



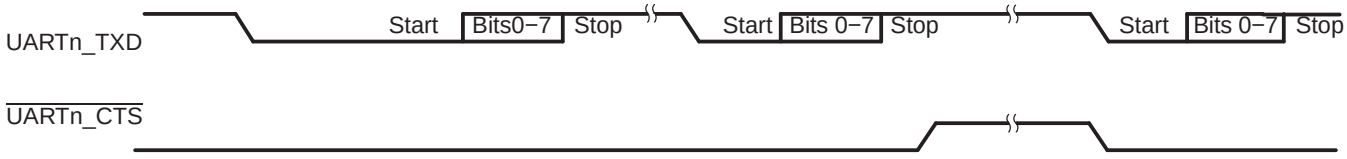
(1) N = Receiver FIFO trigger level.

(2) The two blocks in dashed lines cover the case where an additional byte is sent.

4.7.2.5.4.2 UARTn_CTS Behavior

The transmitter checks UARTn_CTS before sending the next data byte. If UARTn_CTS is active, the transmitter sends the next byte. To stop the transmitter from sending the following byte, UARTn_CTS must be released before the middle of the last STOP bit that is currently being sent (see Figure 4-162). When flow control is enabled, UARTn_CTS level changes do not trigger interrupts because the device automatically controls its own transmitter. Without autoflow control, the transmitter sends any data present in the transmitter FIFO and a receiver overrun error may result.

Figure 4-162. Autoflow Functional Timing Waveforms for UARTn_CTS



(1) When UARTn_CTS is active (low), the transmitter keeps sending serial data out.

(2) When UARTn_CTS goes high before the middle of the last STOP bit of the current byte, the transmitter finishes sending the current byte but it does not send the next byte.

(3) When UARTn_CTS goes from high to low, the transmitter begins sending data again.

4.7.2.5.5 Loopback Control

The UART can be placed in the diagnostic mode using the LOOP bit in the modem control register (MCR), which internally connects the UART output back to the UART input. In this mode, the transmit and receive data paths, the transmitter and receiver interrupts, and the modem control interrupts can be verified without connecting to another UART.

Copyright © 2011, Texas Instruments Incorporated

4.7.2.6 Reset Considerations

4.7.2.6.1 Software Reset Considerations

Two bits in the power and emulation management register (PWREMU_MGMT) control resetting the parts of the UART:

- The UTRST bit controls resetting the transmitter only. If UTRST = 1, the transmitter is active; if UTRST = 0, the transmitter is in reset.
- The URRST bit controls resetting the receiver only. If URRST = 1, the receiver is active; if URRST = 0, the receiver is in reset.

In each case, putting the receiver and/or transmitter in reset will reset the state machine of the affected portion but does not affect the UART registers.

4.7.2.6.2 Hardware Reset Considerations

When the processor RESET pin is asserted, the entire processor is reset and is held in the reset state until the RESET pin is released. As part of a device reset, the UART state machine is reset and the UART registers are forced to their default states. The default states of the registers are shown in .

4.7.2.7 Initialization

The following steps are required to initialize the UART:

1. Perform the necessary device pin multiplexing setup (see your device-specific data manual).
2. Set the desired baud rate by writing the appropriate clock divisor values to the divisor latch registers (DLL and DLH).
3. If the FIFOs will be used, select the desired trigger level and enable the FIFOs by writing the appropriate values to the FIFO control register (FCR). The FIFOEN bit in FCR must be set first, before the other bits in FCR are configured.
4. Choose the desired protocol settings by writing the appropriate values to the line control register (LCR).
5. If autoflow control is desired, write appropriate values to the modem control register (MCR). Note that all UARTs do not support autoflow control, see your device-specific data manual for supported features.
6. Choose the desired response to emulation suspend events by configuring the FREE bit and enable the UART by setting the UTRST and URRST bits in the power and emulation management register (PWREMU_MGMT).

4.7.2.8 Interrupt Support

4.7.2.8.1 Interrupt Events and Requests

The UART generates the interrupt requests described in Table 4-168. All requests are multiplexed through an arbiter to a single UART interrupt request to the CPU, as shown in Figure 4-163. Each of the interrupt requests has an enable bit in the interrupt enable register (IER) and is recorded in the interrupt identification register (IIR).

If an interrupt occurs and the corresponding enable bit is set to 1, the interrupt request is recorded in IIR and is forwarded to the CPU. If an interrupt occurs and the corresponding enable bit is cleared to 0, the interrupt request is blocked. The interrupt request is neither recorded in IIR nor forwarded to the CPU.

4.7.2.8.2 Interrupt Multiplexing

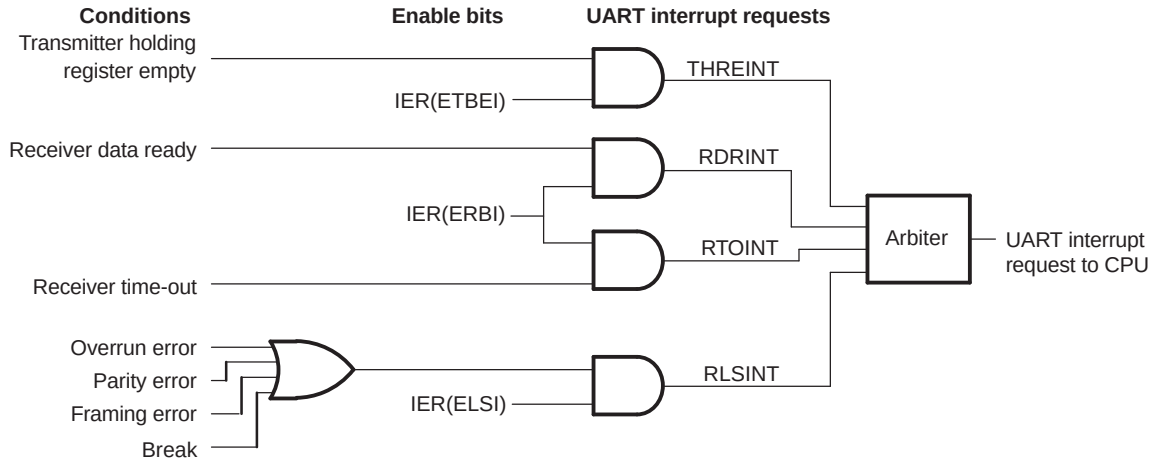
The UARTs have dedicated interrupt signals to the CPU and the interrupts are not multiplexed with any other interrupt source.

Copyright © 2011, Texas Instruments Incorporated

Table 4-168. UART Interrupt Requests Descriptions

UART Interrupt Request	Interrupt Source	Comment
THREINT	THR-empty condition: The transmitter holding register (THR) or the transmitter FIFO is empty. All of the data has been copied from THR to the transmitter shift register (TSR).	If THREINT is enabled in IER, by setting the ETBEI bit, it is recorded in IIR. As an alternative to using THREINT, the CPU can poll the THRE bit in the line status register (LSR).
RDAINT	Receive data available in non-FIFO mode or trigger level reached in the FIFO mode.	If RDAINT is enabled in IER, by setting the ERBI bit, it is recorded in IIR. As an alternative to using RDAINT, the CPU can poll the DR bit in the line status register (LSR). In the FIFO mode, this is not a functionally equivalent alternative because the DR bit does not respond to the FIFO trigger level. The DR bit only indicates the presence or absence of unread characters.
RTOINT	Receiver time-out condition (in the FIFO mode only): No characters have been removed from or input to the receiver FIFO during the last four character times (see Table 4-167), and there is at least one character in the receiver FIFO during this time.	The receiver time-out interrupt prevents the UART from waiting indefinitely, in the case when the receiver FIFO level is below the trigger level and thus does not generate a receiver data-ready interrupt. If RTOINT is enabled in IER, by setting the ERBI bit, it is recorded in IIR. There is no status bit to reflect the occurrence of a time-out condition.
RLSINT	Receiver line status condition: An overrun error, parity error, framing error, or break has occurred.	If RLSINT is enabled in IER, by setting the ELSI bit, it is recorded in IIR. As an alternative to using RLSINT, the CPU can poll the following bits in the line status register (LSR): overrun error indicator (OE), parity error indicator (PE), framing error indicator (FE), and break indicator (BI).

Figure 4-163. UART Interrupt Request Enable Paths



Copyright © 2011, Texas Instruments Incorporated

4.7.2.9 DMA Event Support

In the FIFO mode, the UART generates the following two DMA events:

- **Receive event (URXEVT):** The trigger level for the receiver FIFO (1, 4, 8, or 14 characters) is set with the RXFIFTL bit in the FIFO control register (FCR). Every time the trigger level is reached or a receiver time-out occurs, the UART sends a receive event to the EDMA controller. In response, the EDMA controller reads the data from the receiver FIFO by way of the receiver buffer register (RBR). Note that the receive event is not asserted if the data at the top of the receiver FIFO is erroneous even if the trigger level has been reached.
- **Transmit event (UTXEVT):** When the transmitter FIFO is empty (when the last byte in the transmitter FIFO has been copied to the transmitter shift register), the UART sends an UTXEVT signal to the EDMA controller. In response, the EDMA controller refills the transmitter FIFO by way of the transmitter holding register (THR). The UTXEVT signal is also sent to the DMA controller when the UART is taken out of reset using the UTRST bit in the power and emulation management register (PWREMU_MGMT).

Activity in DMA channels can be synchronized to these events. In the non-FIFO mode, the UART generates no DMA events. Any DMA channel synchronized to either of these events must be enabled at the time the UART event is generated. Otherwise, the DMA channel will miss the event and, unless the UART generates a new event, no data transfer will occur.

4.7.2.10 Power Management

The UART peripheral can be placed in reduced-power modes to conserve power during periods of low activity. The power management of the UART peripheral is controlled by the processor Power and Clock Management (PRCM). The PRCM acts as a master controller for power management for all of the peripherals on the device. For detailed information on power management procedures using the PSC, see Chapter 8.

4.7.2.11 Emulation Considerations

The FREE bit in the power and emulation management register (PWREMU_MGMT) determines how the UART responds to an emulation suspend event such as an emulator halt or breakpoint. If FREE = 0 and a transmission is in progress, the UART halts after completing the one-word transmission; if FREE = 0 and a transmission is not in progress, the UART halts immediately. If FREE = 1, the UART does not halt and continues operating normally.

Note also that most emulator accesses are transparent to UART operation. Emulator read operations do not affect any register contents, status bits, or operating states, with the exception of the interrupt identification register (IIR). Emulator writes, however, may affect register contents and may affect UART operation, depending on what register is accessed and what value is written.

The UART registers can be read from or written to during emulation suspend events, even if the UART activity has stopped.

4.7.2.12 Exception Processing

4.7.2.12.1 Divisor Latch Not Programmed

Since the processor reset signal has no effect on the divisor latch, the divisor latch will have an unknown value after power up. If the divisor latch is not programmed after power up, the baud clock (BCLK) will not operate and will instead be set to a constant logic 1 state.

The divisor latch values should always be reinitialized following a processor reset.

4.7.2.12.2 Changing Operating Mode During Busy Serial Communication

Since the serial link characteristics are based on how the control registers are programmed, the UART will expect the control registers to be static while it is busy engaging in a serial communication. Therefore, changing the control registers while the module is still busy communicating with another serial device will most likely cause an error condition and should be avoided.

Copyright © 2011, Texas Instruments Incorporated

4.7.3 Registers

The system programmer has access to and control over any of the UART registers that are listed in Table 4-169. These registers, which control UART operations, receive data, and transmit data, are available at 32-bit addresses in the device memory map.

- RBR, THR, and DLL share one address. When the DLAB bit in LCR is 0, reading from the address gives the content of RBR, and writing to the address modifies THR. When DLAB = 1, all accesses at the address read or modify DLL. DLL can also be accessed with address offset 20h.
- IER and DLH share one address. When DLAB = 0, all accesses read or modify IER. When DLAB = 1, all accesses read or modify DLH. DLH can also be accessed with address offset 24h.
- IIR and FCR share one address. Regardless of the value of the DLAB bit, reading from the address gives the content of IIR, and writing modifies FCR.

Table 4-169. UART Registers

Offset	Acronym	Register Description	Section

4.7.3.1 Receiver Buffer Register (RBR)

The receiver buffer register (RBR) is shown in Figure 4-164 and described in Table 4-170.

The UART receiver section consists of a receiver shift register (RSR) and a receiver buffer register (RBR). When the UART is in the FIFO mode, RBR is a 16-byte FIFO. Timing is supplied by the 16x receiver clock or 13x receiver clock by programming OSM_SEL bit field of MDR register. Receiver section control is a function of the line control register (LCR).

RSR receives serial data from the UARTn_RXD pin. Then RSR concatenates the data and moves it into RBR (or the receiver FIFO). In the non-FIFO mode, when a character is placed in RBR and the receiver data-ready interrupt is enabled (DR = 1 in IER), an interrupt is generated. This interrupt is cleared when the character is read from RBR. In the FIFO mode, the interrupt is generated when the FIFO is filled to the trigger level selected in the FIFO control register (FCR), and it is cleared when the FIFO contents drop below the trigger level.

Access considerations:

RBR, THR, and DLL share one address. To read RBR, write 0 to the DLAB bit in LCR, and read from the shared address. When DLAB = 0, writing to the shared address modifies THR. When DLAB = 1, all accesses at the shared address read or modify DLL.

DLL also has a dedicated address. If you use the dedicated address, you can keep DLAB = 0, so that RBR and THR are always selected at the shared address.

4.7.3.2 Transmitter Holding Register (THR)

The transmitter holding register (THR) is shown in Figure 4-165 and described in Table 4-171.

The UART transmitter section consists of a transmitter hold register (THR) and a transmitter shift register (TSR). When the UART is in the FIFO mode, THR is a 16-byte FIFO. Transmitter section control is a function of the line control register (LCR).

THR receives data from the internal data bus and when TSR is idle, the UART moves the data from THR to TSR. The UART serializes the data in TSR and transmits the data on the TX pin. In the non-FIFO mode, if THR is empty and the THR empty (THRE) interrupt is enabled (ETBEI = 1 in IER), an interrupt is generated. This interrupt is cleared when a character is loaded into THR or the interrupt identification register (IIR) is read. In the FIFO mode, the interrupt is generated when the transmitter FIFO is empty, and it is cleared when at least one byte is loaded into the FIFO or IIR is read.

Access considerations:

RBR, THR, and DLL share one address. To load THR, write 0 to the DLAB bit of LCR, and write to the shared address. When DLAB = 0, reading from the shared address gives the content of RBR. When DLAB = 1, all accesses at the address read or modify DLL.

DLL also has a dedicated address. If you use the dedicated address, you can keep DLAB = 0, so that RBR and THR are always selected at the shared address.

4.7.3.3 Interrupt Enable Register (IER)

The interrupt enable register (IER) is used to individually enable or disable each type of interrupt request that can be generated by the UART. Each interrupt request that is enabled in IER is forwarded to the CPU. IER is shown in Figure 4-166 and described in Table 4-172.

Access considerations:

IER and DLH share one address. To read or modify IER, write 0 to the DLAB bit in LCR. When DLAB = 1, all accesses at the shared address read or modify DLH.

DLH also has a dedicated address. If you use the dedicated address, you can keep DLAB = 0, so that IER is always selected at the shared address.

4.7.3.4 Interrupt Identification Register (IIR)

The interrupt identification register (IIR) is a read-only register at the same address as the FIFO control register (FCR), which is a write-only register. When an interrupt is generated and enabled in the interrupt enable register (IER), IIR indicates that an interrupt is pending in the IPEND bit and encodes the type of interrupt in the INTID bits. Reading IIR clears any THR empty (THRE) interrupts that are pending.

IIR is shown in Figure 4-167 and described in Figure 4-167.

The UART has an on-chip interrupt generation and prioritization capability that permits flexible communication with the CPU. The UART provides three priority levels of interrupts:

- Priority 1 - Receiver line status (highest priority)
- Priority 2 - Receiver data ready or receiver timeout
- Priority 3 - Transmitter holding register empty

The FIFOEN bit in IIR can be checked to determine whether the UART is in the FIFO mode or the non-FIFO mode.

Access consideration:

IIR and FCR share one address. Regardless of the value of the DLAB bit in LCR, reading from the address gives the content of IIR, and writing to the address modifies FCR.

Table 4-173. Interrupt Identification Register (IIR) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7-6	FIFOEN	0-3h	FIFOs enabled.
		0	Non-FIFO mode
		1h-2h	Reserved
		3h	FIFOs are enabled. FIFOEN bit in the FIFO control register (FCR) is set to 1.
5-4	Reserved	0	Reserved
3-1	INTID	0-7h	Interrupt type. See Table 4-174.
		0	Reserved
		1h	Transmitter holding register empty (priority 3)
		2h	Receiver data available (priority 2)
		3h	Receiver line status (priority 1, highest)
		4h-5h	Reserved
		6h	Character timeout indication (priority 2)
		7h	Reserved
0	IPEND		Interrupt pending. When any UART interrupt is generated and is enabled in IER, IPEND is forced to 0. IPEND remains 0 until all pending interrupts are cleared or until a hardware reset occurs. If no interrupts are enabled, IPEND is never forced to 0.
		0	Interrupts pending.
		1	No interrupts pending.

Table 4-174. Interrupt Identification and Interrupt Clearing Information

Priority Level	IIR Bits 3	2	1	0	Interrupt Type	Interrupt Source	Event That Clears Interrupt
None	0	0	0	1	None	None	None
1	0	1	1	0	Receiver line status	Overrun error, parity error, framing error, or break is detected.	For an overrun error, reading the line status register (LSR) clears the interrupt. For a parity error, framing error, or break, the interrupt is cleared only after all the erroneous data have been read.
2	0	1	0	0	Receiver data-ready	Non-FIFO mode: Receiver data is ready.	Non-FIFO mode: The receiver buffer register (RBR) is read.
						FIFO mode: Trigger level reached. If four character times (see Table 4-167) pass with no access of the FIFO, the interrupt is asserted again.	FIFO mode: The FIFO drops below the trigger level.(1)
2	1	1	0	0	Receiver time-out	FIFO mode only: No characters have been removed from or input to the receiver FIFO during the last four character times (see Table 4-167), and there is at least one character in the receiver FIFO during this time.	One of the following events: • A character is read from the receiver FIFO.(1) • A new character arrives in the receiver FIFO. • The URRST bit in the power and emulation management register (PWREMU_MGMT) is loaded with 0.
3	0	0	1	0	Transmitter holding register empty	Non-FIFO mode: Transmitter holding register (THR) is empty. FIFO mode: Transmitter FIFO is empty.	A character is written to the transmitter holding register (THR) or the interrupt identification register (IIR) is read.

(1) In the FIFO mode, the receiver data-ready interrupt or receiver time-out interrupt is cleared by the CPU or by the DMA controller, whichever reads from the receiver FIFO first.

4.7.3.5 FIFO Control Register (FCR)

The FIFO control register (FCR) is a write-only register at the same address as the interrupt identification register (IIR), which is a read-only register. Use FCR to enable and clear the FIFOs and to select the receiver FIFO trigger level FCR is shown in Figure 4-168 and described in Table 4-175. The FIFOEN bit must be set to 1 before other FCR bits are written to or the FCR bits are not programmed.

Access consideration:

IIR and FCR share one address. Regardless of the value of the DLAB bit, reading from the address gives the content of IIR, and writing to the address modifies FCR.

CAUTION

For proper communication between the UART and the EDMA controller, the DMAMODE1 bit must be set to 1. Always write a 1 to the DMAMODE1 bit, and after a hardware reset, change the DMAMODE1 bit from 0 to 1.

4.7.3.6 Line Control Register (LCR)

The line control register (LCR) is shown in Figure 4-169 and described in Table 4-176.

The system programmer controls the format of the asynchronous data communication exchange by using LCR. In addition, the programmer can retrieve, inspect, and modify the content of LCR; this eliminates the need for separate storage of the line characteristics in system memory.

Figure 4-169. Line Control Register (LCR)

31								16
Reserved

15	8	7	6	5	4	3	2	1 0
Reserved		DLAB	BC	SP	EPS	PEN	STB	WLS
R-0		R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 4-176. Line Control Register (LCR) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7	DLAB		Divisor latch access bit. The divisor latch registers (DLL and DLH) can be accessed at dedicated addresses or at addresses shared by RBR, THR, and IER. Using the shared addresses requires toggling DLAB to change which registers are selected. If you use the dedicated addresses, you can keep DLAB = 0.
		0	Allows access to the receiver buffer register (RBR), the transmitter holding register (THR), and the interrupt enable register (IER) selected. At the address shared by RBR, THR, and DLL, the CPU can read from RBR and write to THR. At the address shared by IER and DLH, the CPU can read from and write to IER.
		1	Allows access to the divisor latches of the baud generator during a read or write operation (DLL and DLH). At the address shared by RBR, THR, and DLL, the CPU can read from and write to DLL. At the address shared by IER and DLH, the CPU can read from and write to DLH.
6	BC		Break control.
		0	Break condition is disabled.
		1	Break condition is transmitted to the receiving UART. A break condition is a condition where the UARTn_TXD signal is forced to the spacing (cleared) state.
5	SP		Stick parity. The SP bit works in conjunction with the EPS and PEN bits. The relationship between the SP, EPS, and PEN bits is summarized in Table 4-177.
		0	Stick parity is disabled.
		1	Stick parity is enabled. • When odd parity is selected (EPS = 0), the PARITY bit is transmitted and checked as set. • When even parity is selected (EPS = 1), the PARITY bit is transmitted and checked as cleared.
4	EPS		Even parity select. Selects the parity when parity is enabled (PEN = 1). The EPS bit works in conjunction with the SP and PEN bits. The relationship between the SP, EPS, and PEN bits is summarized in Table 4-177.
		0	Odd parity is selected (an odd number of logic 1s is transmitted or checked in the data and PARITY bits).
		1	Even parity is selected (an even number of logic 1s is transmitted or checked in the data and PARITY bits).
3	PEN		Parity enable. The PEN bit works in conjunction with the SP and EPS bits. The relationship between the SP, EPS, and PEN bits is summarized in Table 4-177.
		0	No PARITY bit is transmitted or checked.
		1	Parity bit is generated in transmitted data and is checked in received data between the last data word bit and the first STOP bit.

Copyright © 2011, Texas Instruments Incorporated

Table 4-176. Line Control Register (LCR) Field Descriptions (continued)

Bit	Field	Value	Description
2	STB		Number of STOP bits generated. STB specifies 1, 1.5, or 2 STOP bits in each transmitted character. When STB = 1, the WLS bit determines the number of STOP bits. The receiver clocks only the first STOP bit, regardless of the number of STOP bits selected. The number of STOP bits generated is summarized in Table 4-178.
		0	1 STOP bit is generated.
		1	WLS bit determines the number of STOP bits: • When WLS = 0, 1.5 STOP bits are generated. • When WLS = 1h, 2h, or 3h, 2 STOP bits are generated.
1-0	WLS	0-3h	Word length select. Number of bits in each transmitted or received serial character. When STB = 1, the WLS bit determines the number of STOP bits.
		0	5 bits
		1h	6 bits
		2h	7 bits
		3h	8 bits

Table 4-177. Relationship Between ST, EPS, and PEN Bits in LCR

ST Bit	EPS Bit	PEN Bit	Parity Option
x	x	0	Parity disabled: No PARITY bit is transmitted or checked
0	0	1	Odd parity selected: Odd number of logic 1s
0	1	1	Even parity selected: Even number of logic 1s
1	0	1	Stick parity selected with PARITY bit transmitted and checked as set
1	1	1	Stick parity selected with PARITY bit transmitted and checked as cleared

Table 4-178. Number of STOP Bits Generated

STB Bit	WLS Bits	Word Length Selected with WLS Bits	Number of STOP Bits Generated	Baud Clock (BCLK) Cycles
0	x	Any word length	1	16
1	0h	5 bits	1.5	24
1	1h	6 bits	2	32
1	2h	7 bits	2	32
1	3h	8 bits	2	32

4.7.3.7 Modem Control Register (MCR)

The modem control register (MCR) is shown in Figure 4-170 and described in Table 4-179. The modem control register provides the ability to enable/disable the autoflow functions, and enable/disable the loopback function for diagnostic purposes.

Figure 4-170. Modem Control Register (MCR)

31							16
Reserved							
R-0							
15		**6**	**5**	**4**	**3**	**2**	**1**	**0**
Reserved			AFE[1]	LOOP	OUT2	OUT1	RTS[1]	Rsvd
R-0			R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

(1) All UARTs do not support this feature, see your device-specific data manual for supported features. If this feature is not available, this bit is reserved and should be cleared to 0.

Table 4-179. Modem Control Register (MCR) Field Descriptions

Bit	Field	Value	Description
31-6	Reserved	0	Reserved
5	AFE		Autoflow control enable. Autoflow control allows the $\overline{\text{UARTn_RTS}}$ and $\overline{\text{UARTn_CTS}}$ signals to provide handshaking between UARTs during data transfer. When AFE = 1, the RTS bit determines the autoflow control enabled. Note that all UARTs do not support this feature, see your device-specific data manual for supported features. If this feature is not available, this bit is reserved and should be cleared to 0.
		0	Autoflow control is disabled.
		1	Autoflow control is enabled: • When RTS = 0, $\overline{\text{UARTn_CTS}}$ is only enabled. • When RTS = 1, $\overline{\text{UARTn_RTS}}$ and $\overline{\text{UARTn_CTS}}$ are enabled.
4	LOOP		Loop back mode enable. LOOP is used for the diagnostic testing using the loop back feature.
		0	Loop back mode is disabled.
		1	Loop back mode is enabled. When LOOP is set, the following occur: • The UARTn_TXD signal is set high. • The UARTn_RXD pin is disconnected • The output of the transmitter shift register (TSR) is lopped back in to the receiver shift register (RSR) input.
3	OUT2	0	OUT2 Control Bit
2	OUT1	0	OUT1 Control Bit
1	RTS		RTS control. When AFE = 1, the RTS bit determines the autoflow control enabled. Note that all UARTs do not support this feature, see your device-specific data manual for supported features. If this feature is not available, this bit is reserved and should be cleared to 0.
		0	$\overline{\text{UARTn_RTS}}$ is disabled, $\overline{\text{UARTn_CTS}}$ is only enabled.
		1	$\overline{\text{UARTn_RTS}}$ and $\overline{\text{UARTn_CTS}}$ are enabled.
0	Reserved	0	Reserved

4.7.3.8 Line Status Register (LSR)

The line status register (LSR) is shown in Figure 4-171 and described in Table 4-180. LSR provides information to the CPU concerning the status of data transfers. LSR is intended for read operations only; do not write to this register. Bits 1 through 4 record the error conditions that produce a receiver line status interrupt.

Figure 4-171. Line Status Register (LSR)

31								16
Reserved								
R-0								
15	8	7	6	5	4	3	2	1	0
Reserved		RXFIFOE	TEMT	THRE	BI	FE	PE	OE	DR
R-0		R-0	R-1	R-1	R-0	R-0	R-0	R-0	R-0

LEGEND: R = Read only; -*n* = value after reset

Table 4-180. Line Status Register (LSR) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7	RXFIFOE		Receiver FIFO error.
			In non-FIFO mode:
		0	There has been no error, or RXFIFOE was cleared because the CPU read the erroneous character from the receiver buffer register (RBR).
		1	There is a parity error, framing error, or break indicator in the receiver buffer register (RBR).
			In FIFO mode:
		0	There has been no error, or RXFIFOE was cleared because the CPU read the erroneous character from the receiver FIFO and there are no more errors in the receiver FIFO.
		1	At least one parity error, framing error, or break indicator in the receiver FIFO.
6	TEMT		Transmitter empty (TEMT) indicator.
			In non-FIFO mode:
		0	Either the transmitter holding register (THR) or the transmitter shift register (TSR) contains a data character.
		1	Both the transmitter holding register (THR) and the transmitter shift register (TSR) are empty.
			In FIFO mode:
		0	Either the transmitter FIFO or the transmitter shift register (TSR) contains a data character.
		1	Both the transmitter FIFO and the transmitter shift register (TSR) are empty.
5	THRE		Transmitter holding register empty (THRE) indicator. If the THRE bit is set and the corresponding interrupt enable bit is set (ETBEI = 1 in IER), an interrupt request is generated.
			In non-FIFO mode:
		0	Transmitter holding register (THR) is not empty. THR has been loaded by the CPU.
		1	Transmitter holding register (THR) is empty (ready to accept a new character). The content of THR has been transferred to the transmitter shift register (TSR).
			In FIFO mode:
		0	Transmitter FIFO is not empty. At least one character has been written to the transmitter FIFO. You can write to the transmitter FIFO if it is not full.
		1	Transmitter FIFO is empty. The last character in the FIFO has been transferred to the transmitter shift register (TSR).

Copyright © 2011, Texas Instruments Incorporated

Table 4-180. Line Status Register (LSR) Field Descriptions (continued)

Bit	Field	Value	Description
4	BI		Break indicator. The BI bit is set whenever the receive data input (UARTn_RXD) was held low for longer than a full-word transmission time. A full-word transmission time is defined as the total time to transmit the START, data, PARITY, and STOP bits. If the BI bit is set and the corresponding interrupt enable bit is set (ELSI = 1 in IER), an interrupt request is generated.
			In non-FIFO mode:
		0	No break has been detected, or the BI bit was cleared because the CPU read the erroneous character from the receiver buffer register (RBR).
		1	A break has been detected with the character in the receiver buffer register (RBR).
			In FIFO mode:
		0	No break has been detected, or the BI bit was cleared because the CPU read the erroneous character from the receiver FIFO and the next character to be read from the FIFO has no break indicator.
		1	A break has been detected with the character at the top of the receiver FIFO.
3	FE		Framing error (FE) indicator. A framing error occurs when the received character does not have a valid STOP bit. In response to a framing error, the UART sets the FE bit and waits until the signal on the RX pin goes high. Once the RX signal goes high, the receiver is ready to detect a new START bit and receive new data. If the FE bit is set and the corresponding interrupt enable bit is set (ELSI = 1 in IER), an interrupt request is generated.
			In non-FIFO mode:
		0	No framing error has been detected, or the FE bit was cleared because the CPU read the erroneous data from the receiver buffer register (RBR).
		1	A framing error has been detected with the character in the receiver buffer register (RBR).
			In FIFO mode:
		0	No framing error has been detected, or the FE bit was cleared because the CPU read the erroneous data from the receiver FIFO and the next character to be read from the FIFO has no framing error.
		1	A framing error has been detected with the character at the top of the receiver FIFO.
2	PE		Parity error (PE) indicator. A parity error occurs when the parity of the received character does not match the parity selected with the EPS bit in the line control register (LCR). If the PE bit is set and the corresponding interrupt enable bit is set (ELSI = 1 in IER), an interrupt request is generated.
			In non-FIFO mode:
		0	No parity error has been detected, or the PE bit was cleared because the CPU read the erroneous data from the receiver buffer register (RBR).
		1	A parity error has been detected with the character in the receiver buffer register (RBR).
			In FIFO mode:
		0	No parity error has been detected, or the PE bit was cleared because the CPU read the erroneous data from the receiver FIFO and the next character to be read from the FIFO has no parity error.
		1	A parity error has been detected with the character at the top of the receiver FIFO.
1	OE		Overrun error (OE) indicator. An overrun error in the non-FIFO mode is different from an overrun error in the FIFO mode. If the OE bit is set and the corresponding interrupt enable bit is set (ELSI = 1 in IER), an interrupt request is generated.
			In non-FIFO mode:
		0	No overrun error has been detected, or the OE bit was cleared because the CPU read the content of the line status register (LSR).
		1	Overrun error has been detected. Before the character in the receiver buffer register (RBR) could be read, it was overwritten by the next character arriving in RBR.
			In FIFO mode:
		0	No overrun error has been detected, or the OE bit was cleared because the CPU read the content of the line status register (LSR).
		1	Overrun error has been detected. If data continues to fill the FIFO beyond the trigger level, an overrun error occurs only after the FIFO is full and the next character has been completely received in the shift register. An overrun error is indicated to the CPU as soon as it happens. The new character overwrites the character in the shift register, but it is not transferred to the FIFO.

Copyright © 2011, Texas Instruments Incorporated

Table 4-180. Line Status Register (LSR) Field Descriptions (continued)

Bit	Field	Value	Description
0	DR		Data-ready (DR) indicator for the receiver. If the DR bit is set and the corresponding interrupt enable bit is set (ERBI = 1 in IER), an interrupt request is generated.
			In non-FIFO mode:
		0	Data is not ready, or the DR bit was cleared because the character was read from the receiver buffer register (RBR).
		1	Data is ready. A complete incoming character has been received and transferred into the receiver buffer register (RBR).
			In FIFO mode:
		0	Data is not ready, or the DR bit was cleared because all of the characters in the receiver FIFO have been read.
		1	Data is ready. There is at least one unread character in the receiver FIFO. If the FIFO is empty, the DR bit is set as soon as a complete incoming character has been received and transferred into the FIFO. The DR bit remains set until the FIFO is empty again.

4.7.3.9 Modem Status Register (MSR)

The Modem status register (MSR) is shown in Figure 4-172 and described in Table 4-181. MSR provides information to the CPU concerning the status of modem control signals. MSR is intended for read operations only; do not write to this register.

Figure 4-172. Modem Status Register (MSR)

31								16
Reserved								
R-0								
15	8	7	6	5	4	3	2	1	0

LEGEND: R = Read only; -*n* = value after reset

Table 4-181. Modem Status Register (MSR) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7	CD	0	Complement of the Carrier Detect input. When the UART is in the diagnostic test mode (loopback mode MCR[4] = 1), this bit is equal to the MCR bit 3 (OUT2).
6	RI	0	Complement of the Ring Indicator input. When the UART is in the diagnostic test mode (loopback mode MCR[4] = 1), this bit is equal to the MCR bit 2 (OUT1).
5	DSR	0	Complement of the Data Set Ready input. When the UART is in the diagnostic test mode (loopback mode MCR[4] = 1), this bit is equal to the MCR bit 0 (DTR).
4	CTS	0	Complement of the Clear To Send input. When the UART is in the diagnostic test mode (loopback mode MCR[4] = 1), this bit is equal to the MCR bit 1 (RTS).
3	DCD	0	Change in DCD indicator bit. DCD indicates that the DCD input has changed state since the last time it was read by the CPU. When DCD is set and the modem status interrupt is enabled, a modem status interrupt is generated.
2	TERI	0	Trailing edge of RI (TERI) indicator bit. TERI indicates that the RI input has changed from a low to a high. When TERI is set and the modem status interrupt is enabled, a modem status interrupt is generated.
1	DDSR	0	Change in DSR indicator bit. DDSR indicates that the DSR input has changed state since the last time it was read by the CPU. When DDSR is set and the modem status interrupt is enabled, a modem status interrupt is generated.
0	DCTS	0	Change in CTS indicator bit. DCTS indicates that the CTS input has changed state since the last time it was read by the CPU. When DCTS is set (autoflow control is not enabled and the modem status interrupt is enabled), a modem status interrupt is generated. When autoflow control is enabled, no interrupt is generated.

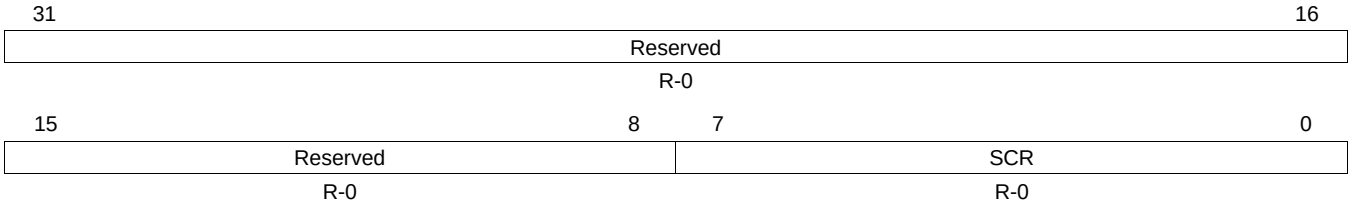
4.7.3.10 Scratch Pad Register (SCR)

The Scratch Pad register (SCR) is shown in Figure 4-173 and described in Table 4-182. SCR is intended for programmer's use as a scratch pad. It temporarily holds the programmer's data without affecting UART operation.

Figure 4-173. Scratch Pad Register (SCR)



LEGEND: R = Read only; -*n* = value after reset

Table 4-182. Scratch Pad Register (MSR) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7-0	SCR	0	These bits are intended for the programmer's use as a scratch pad in the sense that it temporarily holds the programmer's data without affecting any other UART operation.

4.7.3.11 Divisor Latches (DLL and DLH)

Two 8-bit register fields (DLL and DLH), called divisor latches, store the 16-bit divisor for generation of the baud clock in the baud generator. The latches are in DLH and DLL. DLH holds the most-significant bits of the divisor, and DLL holds the least-significant bits of the divisor. These divisor latches must be loaded during initialization of the UART in order to ensure desired operation of the baud generator. Writing to the divisor latches results in two wait states being inserted during the write access while the baud generator is loaded with the new value.

Access considerations:

- RBR, THR, and DLL share one address. When DLAB = 1 in LCR, all accesses at the shared address are accesses to DLL. When DLAB = 0, reading from the shared address gives the content of RBR, and writing to the shared address modifies THR.
- IER and DLH share one address. When DLAB = 1 in LCR, accesses to the shared address read or modify to DLH. When DLAB = 0, all accesses at the shared address read or modify IER.

DLL and DLH also have dedicated addresses. If you use the dedicated addresses, you can keep the DLAB bit cleared, so that RBR, THR, and IER are always selected at the shared addresses.

The divisor LSB latch (DLL) is shown in Figure 4-174 and described in Table 4-183. The divisor MSB latch (DLH) is shown in Figure 4-175 and described in Table 4-184.

Copyright © 2011, Texas Instruments Incorporated

Table 4-187. Power and Emulation Management Register (PWREMU_MGMT) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved
15	Reserved	0	Reserved. This bit must always be written with a 0.
14	UTRST		UART transmitter reset. Resets and enables the transmitter.
		0	Transmitter is disabled and in reset state.
		1	Transmitter is enabled.
13	URRST		UART receiver reset. Resets and enables the receiver.
		0	Receiver is disabled and in reset state.
		1	Receiver is enabled.
12-1	Reserved	1	Reserved
0	FREE		Free-running enable mode bit. This bit determines the emulation mode functionality of the UART. When halted, the UART can handle register read/write requests, but does not generate any transmission/reception, interrupts or events.
		0	If a transmission is not in progress, the UART halts immediately. If a transmission is in progress, the UART halts after completion of the one-word transmission.
		1	Free-running mode is enabled; UART continues to run normally.

4.8 eCAP

For information on eCAP, see Section 15.3. For the eCAP register descriptions, see Section 15.3.4.

4.9 CFG

The PRUSS CFG block contains the registers for control and status of power management, memory parity, and enhanced PRU GP ports functions. See the following register sections for details.

4.9.1 PRUSS_CFG Registers

Table 4-189 lists the memory-mapped registers for the PRUSS_CFG. All register offset addresses not listed in Table 4-189 should be considered as reserved locations and the register contents should not be modified.

Table 4-189. PRUSS_CFG REGISTERS

Offset	Acronym	Register Description	Section
0h	REVID	The Revision Register contains the ID and revision information.	Section 15.4.3.25
4h	SYSCFG	The System Configuration Register defines the power IDLE and STANDBY modes.	Section 4.9.1.2
8h	GPCFG0	The General Purpose Configuration 0 Register defines the GPI/O configuration for PRU0.	Section 4.9.1.3
Ch	GPCFG1	The General Purpose Configuration 1 Register defines the GPI/O configuration for PRU1.	Section 4.9.1.4
10h	CGR	The Clock Gating Register controls the state of Clock Management of the different modules. Software should not clear {module}_CLK_EN until {module}_CLK_STOP_ACK is 0x1.	Section 4.9.1.5
14h	ISRP	The IRQ Status Raw Parity register is a snapshot of the IRQ raw status for the PRUSS memory parity events. The raw status is set even if the event is not enabled.	Section 4.9.1.6
18h	ISP	The IRQ Status Parity Register is a snapshot of the IRQ status for the PRUSS memory parity events. The status is set only if the event is enabled. Write 1 to clear the status after the interrupt has been serviced.	Section 4.9.1.7
1Ch	IESP	The IRQ Enable Set Parity Register enables the IRQ PRUSS memory parity events.	Section 4.9.1.8
20h	IECP	The IRQ Enable Clear Parity Register disables the IRQ PRUSS memory parity events.	Section 4.9.1.9
24h	SCRP	SCR Priority Register defines the priority of some of the elements in the SCR. Lower numbers indicate higher priority level.	Section 4.9.1.10
28h	PMAO	The PRU Master OCP Address Offset Register enables for the PRU OCP Master Port Address to have an offset of minus 0x0008_0000. This enables the PRU to access External Host address space starting at 0x00000.	Section 4.9.1.11
2Ch	MII_RT	The MII_RT Event Enable Register enables Ethercat (or MII_RT) mode events to the PRUSS INTC.	Section 4.9.1.12
30h	IEPCLK	The IEP Clock Source Register defines the source of the IEP clock.	Section 4.9.1.13
34h	SPP	The Scratch Pad Priority and Configuration Register defines the access priority assigned to the PRU cores and configures the scratch pad XFR shift functionality.	Section 4.9.1.14
40h	PIN_MX	The Pin Mux Select Register defines the state of the PRUSS internal pinmuxing.	Section 4.9.1.15

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 4-203. SPP Register Field Descriptions

Bit	Field	Type	Reset	Description
1	XFR_SHIFT_EN	R/W	0h	Enables XIN/XOUT shift functionality. When enabled, R0[4:0] (internal to PRU) defines the 32-bit offset for XIN and XOUT operations with the scratch pad. 0x0 = Disabled. 0x1 = Enabled.
0	PRU1_PAD_HP_EN	R/W	0h	Defines which PRU wins write cycle arbitration to a common scratch pad bank. The PRU which has higher priority will always perform the write cycle with no wait states. The lower PRU will get stalled/wait states until higher PRU is not performing write cycles. If the lower priority PRU writes to the same byte has the higher priority PRU, then the lower priority PRU will over write the bytes. 0x0 = PRU0 has highest priority. 0x1 = PRU1 has highest priority.

5.1 Introduction

This chapter describes the 2D/3D graphics accelerator (SGX) for the device.

NOTE: The SGX subsystem is a Texas Instruments instantiation of the POWERVR® SGX530 core from Imagination Technologies Ltd.

This document contains materials that are ©2003-2007 Imagination Technologies Ltd.

POWERVR® and USSE™ are trademarks or registered trademarks of Imagination Technologies Ltd.

The 2D/3D graphics accelerator (SGX) subsystem accelerates 2-dimensional (2D) and 3-dimensional (3D) graphics applications. The SGX subsystem is based on the POWERVR® SGX core from Imagination Technologies. SGX is a new generation of programmable POWERVR graphic cores. The POWERVR SGX530 v1.2.5 architecture is scalable and can target all market segments from mainstream mobile devices to high-end desktop graphics. Targeted applications include feature phone, PDA, and hand-held games.

5.1.1 POWERVR SGX Main Features

- 2D graphics, 3D graphics, vector graphics, and programming support for GP-GPU functions
- Tile-based architecture
- Universal scalable shader engine (USSE™) – multithreaded engine incorporating pixel and vertex shader functionality
- Advanced shader feature set – in excess of Microsoft VS3.0, PS3.0, and OpenGL2.0
- Industry-standard API support – Direct3D Mobile, OpenGL ES 1.1 and 2.0, OpenVG v1.0.1
- Fine-grained task switching, load balancing, and power management
- Advanced geometry direct memory access (DMA) driven operation for minimum CPU interaction
- Programmable high-quality image anti-aliasing
- POWERVR SGX core MMU for address translation from the core virtual address to the external physical address (up to 4GB address range)
- Fully virtualized memory addressing for OS operation in a unified memory architecture
- Advanced and standard 2D operations [e.g., vector graphics, BLTs (block level transfers), ROPs (raster operations)]
- 32K stride support

5.1.2 SGX 3D Features

- Deferred pixel shading
- On-chip tile floating point depth buffer
- 8-bit stencil with on-chip tile stencil buffer
- 8 parallel depth/stencil tests per clock
- Scissor test
- Texture support:
  - Cube map
  - Projected textures
  - 2D textures
  - Nonsquare textures
- Texture formats:
  - RGBA 8888, 565, 1555
  - Monochromatic 8, 16, 16f, 32f, 32int
  - Dual channel, 8:8, 16:16, 16f:16f

Copyright © 2011, Texas Instruments Incorporated

  - Compressed textures PVR-TC1, PVR-TC2, ETC1
  - Programmable support for all YUV formats
- Resolution support:
  - Frame buffer maximum size = 2048 x 2048
  - Texture maximum size = 2048 x 2048
- Texture filtering:
  - Bilinear, trilinear, anisotropic
  - Independent minimum and maximum control
- Antialiasing:
  - 4x multisampling
  - Up to 16x full scene anti-aliasing
  - Programmable sample positions
- Indexed primitive list support
  - Bus mastered
- Programmable vertex DMA
- Render to texture:
  - Including twiddled formats
  - Auto MipMap generation
- Multiple on-chip render targets (MRT).
  Note: Performance is limited when the on-chip memory is not available.

5.1.3 Universal Scalable Shader Engine (USSE) – Key Features

The USSE is the engine core of the POWERVR SGX architecture and supports a broad range of instructions.

- Single programming model:
  - Multithreaded with 16 simultaneous execution threads and up to 64 simultaneous data instances
  - Zero-cost swapping in, and out, of threads
  - Cached program execution model
  - Dedicated pixel processing instructions
  - Dedicated video encode/decode instructions
- SIMD execution unit supporting operations in:
  - 32-bit IEEE float
  - 2-way 16-bit fixed point
  - 4-way 8-bit integer
  - 32-bit bit-wise (logical only)
- Static and dynamic flow control:
  - Subroutine calls
  - Loops
  - Conditional branches
  - Zero-cost instruction predication
- Procedural geometry:
  - Allows generation of primitives
  - Effective geometry compression
  - High-order surface support
- External data access:
  - Permits reads from main memory using cache

Copyright © 2011, Texas Instruments Incorporated

- Permits writes to main memory
- Data fence facility
- Dependent texture reads

5.1.4 Unsupported Features

There are no unsupported SGX530 features for this device.

Copyright © 2011, Texas Instruments Incorporated

5.2 Integration

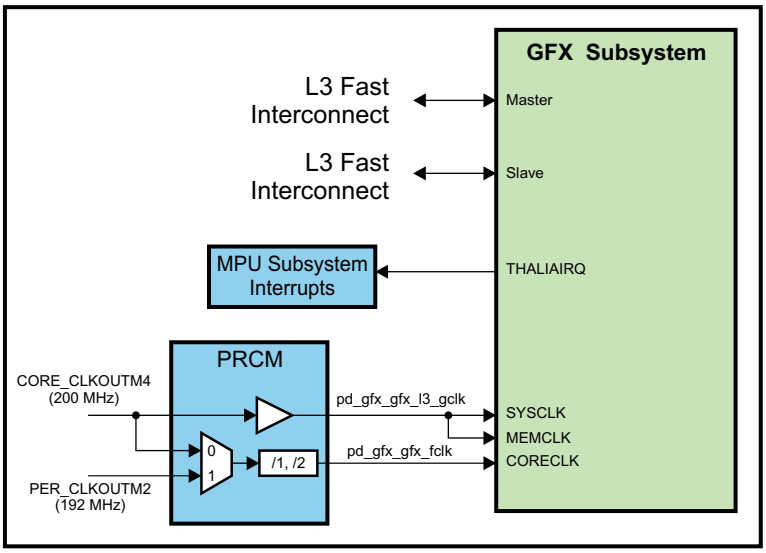

Figure 5-1. SGX530 Integration

5.2.1 SGX530 Connectivity Attributes

The general connectivity attributes of the SGX530 are shown in the following table.

Table 5-1. SGX530 Connectivity Attributes

Attributes	Type
Power domain	GFX Domain
Clock domain	SGX_CLK
Reset signals	SGX_RST
Idle/Wakeup signals	Smart Idle Initiator Standby
Interrupt request	THALIAIRQ (GFXINT) to MPU Subsystem
DMA request	None
Physical address	L3 Fast slave port

5.2.2 SGX530 Clock and Reset Management

The SGX530 uses separate functional and interface clocks. The SYSCLK is the clock for the slave interface and runs at the L3F frequency. The MEMCLK is the clock for the memories and master interface and also runs at the L3F frequency. The CORECLK is the functional clock. It can be sourced from either the L3F clock (CORE_CLKOUTM4) or from the 192 MHz PER_CLKOUTM2 and can optionally be divided by 2.

Table 5-2. SGX530 Clock Signals

Clock signal	Max Freq	Reference / Source	Comments
SYSCLK Interface clock	200 MHz	CORE_CLKOUTM4	pd_gfx_gfx_l3_gclk From PRCM
MEMCLK Memory Clock	200 MHz	CORE_CLKOUTM4	pd_gfx_gfx_l3_gclk From PRCM
CORECLK Functional clock	200 MHz	PER_CLKOUTM2 or CORE_CLKOUTM4	pd_gfx_gfx_fclk From PRCM

Copyright © 2011, Texas Instruments Incorporated

5.2.3 SGX530 Pin List

The SGX530 module does not include any external interface pins.

Copyright © 2011, Texas Instruments Incorporated

5.3 Functional Description

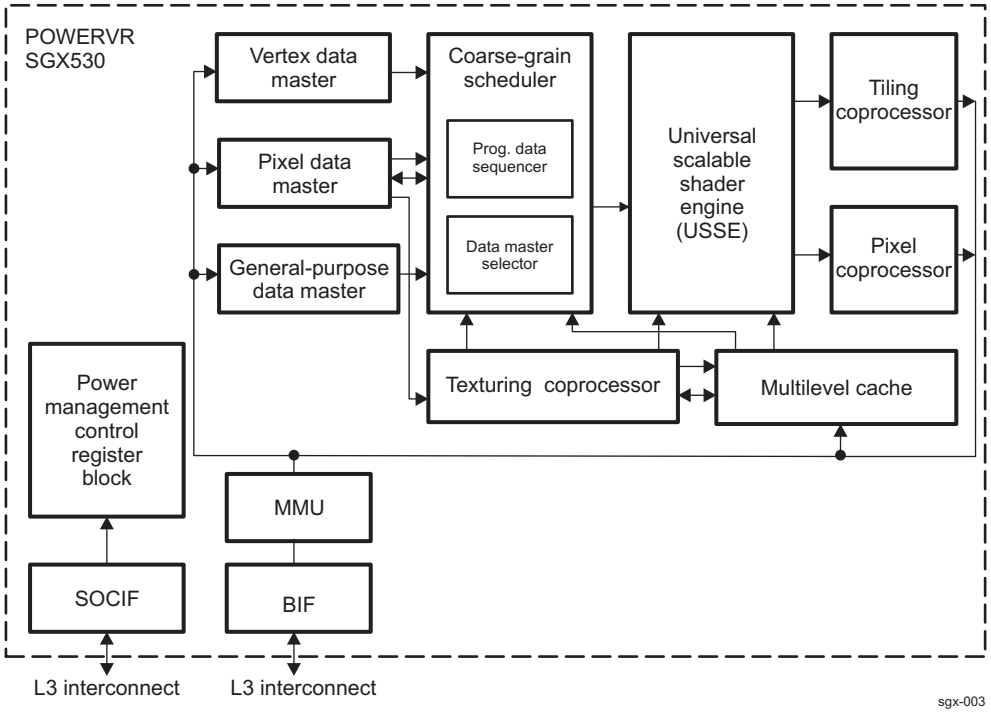
5.3.1 SGX Block Diagram

The SGX subsystem is based on the POWERVR® SGX530 core from Imagination Technologies. The architecture uses programmable and hard coded pipelines to perform various processing tasks required in 2D, 3D, and video processing. The SGX architecture comprises the following elements:

- Coarse grain scheduler
  - Programmable data sequencer (PDS)
  - Data master selector (DMS)
- Vertex data master (VDM)
- Pixel data master (PDM)
- General-purpose data master
- USSE
- Tiling coprocessor
- Pixel coprocessor
- Texturing coprocessor
- Multilevel cache

Figure 5-2 shows a block diagram of the SGX cores.

Figure 5-2. SGX Block Diagram



5.3.2 SGX Elements Description

The coarse grain scheduler (CGS) is the main system controller for the POWERVR SGX architecture. It consists of two stages, the DMS and the PDS. The DMS processes requests from the data masters and determines which tasks can be executed given the resource requirements. The PDS then controls the loading and processing of data on the USSE.

There are three data masters in the SGX core:

Copyright © 2011, Texas Instruments Incorporated

- The VDM is the initiator of transform and lighting processing within the system. The VDM reads an input control stream, which contains triangle index data and state data. The state data indicates the PDS program, size of the vertices, and the amount of USSE output buffer resource available to the VDM. The triangle data is parsed to determine unique indices that must be processed by the USSE. These are grouped together according to the configuration provided by the driver and presented to the DMS.
- The PDM is the initiator of rasterization processing within the system. Each pixel pipeline processes pixels for a different half of a given tile, which allows for optimum efficiency within each pipe due to locality of data. It determines the amount of resource required within the USSE for each task. It merges this with the state address and issues a request to the DMS for execution on the USSE.
- The general-purpose data master responds to events within the system (such as end of a pass of triangles from the ISP, end of a tile from the ISP, end of render, or parameter stream breakpoint event). Each event causes either an interrupt to the host or synchronized execution of a program on the PDS. The program may, or may not cause a subsequent task to be executed on the USSE.

The USSE is a user-programmable processing unit. Although general in nature, its instructions and features are optimized for three types of task: processing vertices (vertex shading), processing pixels (pixel shading), and video/imaging processing.

The multilevel cache is a 2-level cache consisting of two modules: the main cache and the mux/arbiter/demux/decompression unit (MADD). The MADD is a wrapper around the main cache module designed to manage and format requests to and from the cache, as well as providing Level 0 caching for texture and USSE requests. The MADD can accept requests from the PDS, USSE, and texture address generator modules. Arbitration, as well as any required texture decompression, are performed between the three data streams.

The texturing coprocessor performs texture address generation and formatting of texture data. It receives requests from either the iterators or USSE modules and translates these into requests in the multilevel cache. Data returned from the cache are then formatted according to the texture format selected, and sent to the USSE for pixel-shading operations.

To process pixels in a tiled manner, the screen is divided into tiles and arranged as groups of tiles by the tiling coprocessor. An inherent advantage of tiling architecture is that a large amount of vertex data can be rejected at this stage, thus reducing the memory storage requirements and the amount of pixel processing to be performed.

The pixel coprocessor is the final stage of the pixel-processing pipeline and controls the format of the final pixel data sent to the memory. It supplies the USSE with an address into the output buffer and then USSE returns the relevant pixel data. The address order is determined by the frame buffer mode. The pixel coprocessor contains a dithering and packing function.

Interrupts

This section describes the interrupts for the device.

6.1 Functional Description

The interrupt controller processes incoming interrupts by masking and priority sorting to produce the interrupt signals for the processor to which it is attached. Figure 6-1 shows the top-level view of interrupt processing.

6.1.1 Interrupt Processing

6.1.1.1 Input Selection

The INTC supports only level-sensitive incoming interrupt detection. A peripheral asserting an interrupt maintains it until software has handled the interrupt and instructed the peripheral to deassert the interrupt. A software interrupt is generated if the corresponding bit in the MPU_INTC.INTCPS_ISR_SETn register is set (register bank number: n = [0,1,2,3] for the MPU subsystem INTC, 128 incoming interrupt lines are supported). The software interrupt clears when the corresponding bit in the MPU_INTC.INTCPS_ISR_CLEARn register is written. Typical use of this feature is software debugging.

6.1.1.2 Masking

6.1.1.3 Individual Masking

Detection of interrupts on each incoming interrupt line can be enabled or disabled independently by the MPU_INTC.INTCPS_MIRn interrupt mask register. In response to an unmasked incoming interrupt, the INTC can generate one of two types of interrupt requests to the processor:

- IRQ: low-priority interrupt request
- FIQ: fast interrupt request

The type of interrupt request is determined by the MPU_INTC.INTCPS_ILRm[0] FIQNIRQ bit (m= [0,127]). The current incoming interrupt status before masking is readable from the MPU_INTC.INTCPS_ITRn register. After masking and IRQ/FIQ selection, and before priority sorting is done, the interrupt status is readable from the MPU_INTC.INTCPS_PENDING_IRQn and MPU_INTC.INTCPS_PENDING_FIQn registers.

6.1.1.4 Priority Masking

To enable faster processing of high-priority interrupts, a programmable priority masking threshold is provided (the MPU_INTC.INTCPS_THRESHOLD[7:0] PRIORITYTHRESHOLD field). This priority threshold allows preemption by higher priority interrupts; all interrupts of lower or equal priority than the threshold are masked. However, priority 0 can never be masked by this threshold; a priority threshold of 0 is treated the same way as priority 1. PRIORITY and PRIORITYTHRESHOLD fields values can be set between 0x0 and 0x7F; 0x0 is the highest priority and 0x7F is the lowest priority. When priority masking is not necessary, a priority threshold value of 0xFF disables the priority threshold mechanism. This value is also the reset default for backward compatibility with previous versions of the INTC.

6.1.1.5 Priority Sorting

A priority level (0 being the highest) is assigned to each incoming interrupt line. Both the priority level and the interrupt request type are configured by the MPU_INTC.INTCPS_ILRm register. If more than one incoming interrupt with the same priority level and interrupt request type occur simultaneously, the highest-numbered interrupt is serviced first. When one or more unmasked incoming interrupts are detected, the INTC separates between IRQ and FIQ using the corresponding MPU_INTC.INTCPS_ILRm[0] FIQNIRQ bit. The result is placed in INTCPS_PENDING_IRQn or INTCPS_PENDING_FIQn If no other interrupts are currently being processed, INTC asserts IRQ/FIQ and starts the priority computation. Priority sorting for IRQ and FIQ can execute in parallel. Each IRQ/FIQ priority sorter determines the highest priority interrupt number. Each priority number is placed in the corresponding MPU_INTC.INTCPS_SIR_IRQ[6:0] ACTIVEIRQ field or MPU_INTC.INTCPS_SIR_FIQ[6:0] ACTIVEFIQ field. The value is preserved until the corresponding MPU_INTC.INTCPS_CONTROL NEWIRQAGR or NEWFIQAGR bit is set. Once the interrupting peripheral device has been serviced and the incoming interrupt deasserted, the user must write to the appropriate NEWIRQAGR or NEWFIQAGR bit to indicate to the INTC the interrupt has been handled. If there are any pending unmasked incoming interrupts for this interrupt request type, the INTC restarts the appropriate priority sorter; otherwise, the IRQ or FIQ interrupt line is deasserted.

Copyright © 2011, Texas Instruments Incorporated

6.1.2 Register Protection

If the MPU_INTC.INTCPS_PROTECTION[0] PROTECTION bit is set, access to the INTC registers is restricted to the supervisor mode. Access to the MPU_INTC.INTCPS_PROTECTION register is always restricted to privileged mode.

6.1.3 Module Power Saving

The INTC provides an auto-idle function in its three clock domains:

- Interface clock
- Functional clock
- Synchronizer clock

The interface clock auto-idle power-saving mode is enabled if the MPU_INTC.INTCPS_SYSCONFIG[0] AUTOIDLE bit is set to 1. When this mode is enabled and there is no activity on the bus interface, the interface clock is disabled internally to the module, thus reducing power consumption. When there is new activity on the bus interface, the interface clock restarts without any latency penalty. After reset, this mode is disabled, by default. The functional clock auto-idle power-saving mode is enabled if the MPU_INTC.INTCPS_IDLE[0] FUNCIDLE bit is set to 0. When this mode is enabled and there is no active interrupt (IRQ or FIQ interrupt being processed or generated) or no pending incoming interrupt, the functional clock is disabled internally to the module, thus reducing power consumption. When a new unmasked incoming interrupt is detected, the functional clock restarts and the INTC processes the interrupt. If this mode is disabled, the interrupt latency is reduced by one cycle. After reset, this mode is enabled, by default. The synchronizer clock allows external asynchronous interrupts to be resynchronized before they are masked. The synchronizer input clock has an auto-idle power-saving mode enabled if the MPU_INTC.INTCPS_IDLE[1] TURBO bit is set to 1. If the auto-idle mode is enabled, the standby power is reduced, but the IRQ or FIQ interrupt latency increases from four to six functional clock cycles. This feature can be enabled dynamically according to the requirements of the device. After reset, this mode is disabled, by default.

6.1.4 Error Handling

The following accesses will cause an error:

- Privilege violation (attempt to access PROTECTION register in user mode or any register in user mode if Protection bit is set)
- Unsupported commands

The following accesses will not cause any error response:

- Access to a non-decoded address
- Write to a read-only register

6.1.5 Interrupt Handling

The IRQ/FIQ interrupt generation takes four INTC functional clock cycles (plus or minus one cycle) if the MPU_INTC.INTCPS_IDLE[1] TURBO bit is set to 0. If the TURBO bit is set to 1, the interrupt generation takes six cycles, but power consumption is reduced while waiting for an interrupt. These latencies can be reduced by one cycle by disabling functional clock auto-idle (MPU_INTC.INTCPS_IDLE[0] FUNCIDLE bit set to 1), but power consumption is increased, so the benefit is minimal. To minimize interrupt latency when an unmasked interrupt occurs, the IRQ or FIQ interrupt is generated before priority sorting completion. The priority sorting takes 10 functional clock cycles, which is less than the minimum number of cycles required for the MPU to switch to the interrupt context after reception of the IRQ or FIQ event.

Any read of the MPU_INTC.INTCPS_SIR_IRQ or MPU_INTC.INTCPS_SIR_FIQ register during the priority sorting process stalls until priority sorting is complete and the relevant register is updated. However, the delay between the interrupt request being generated and the interrupt service routine being executed is such that priority sorting always completes before the MPU_INTC.INTCPS_SIR_IRQ or MPU_INTC.INTCPS_SIR_FIQ register is read.

6.1.6 Basic Programming Model

6.1.6.1 Initialization Sequence

1. Program the MPU_INTC.INTCPS_SYSCONFIG register: If necessary, enable the interface clock autogating by setting the AUTOIDLE bit.
2. Program the MPU_INTC.INTCPS_IDLE register: If necessary, disable functional clock autogating or enable synchronizer autogating by setting the FUNCIDLE bit or TURBO bit accordingly.
3. Program the MPU_INTC.INTCPS_ILRm register for each interrupt line: Assign a priority level and set the FIQNIRQ bit for an FIQ interrupt (by default, interrupts are mapped to IRQ and priority is 0x0 [highest]).
4. Program the MPU_INTC.INTCPS_MIRn register: Enable interrupts (by default, all interrupt lines are masked). NOTE: To program the MPU_INTC.INTCPS_MIRn register, the MPU_INTC.INTCPS_MIR_SETn and MPU_INTC.INTCPS_MIR_CLEARn registers are provided to facilitate the masking, even if it is possible for backward-compatibility to write directly to the MPU_INTC.INTCPS_MIRn register.

6.1.6.2 INTC Processing Sequence

After the INTCPS_MIRn and INTCPS_ILRm registers are configured to enable and assign priorities to incoming interrupts, the interrupt is processed as explained in the following subsections. IRQ and FIQ processing sequences are quite similar, the differences for the FIQ sequence are shown after a '/' character in the code below.

1. One or more unmasked incoming interrupts (M_IRQ_n signals) are received and IRQ or FIQ outputs (IRQ/FIQ) are not currently asserted.
2. If the INTCPS_ILRm[0] FIQNIRQ bit is cleared to 0, the MPU_INTC_IRQ output signal is generated. If the FIQNIRQ bit is set to 1, the MPU_INTC_FIQ output signal is generated.
3. The INTC performs the priority sorting and updates the INTCPS_SIR_IRQ[6:0] ACTIVEIRQ /INTCPS_SIR_FIQ[6:0] ACTIVEFIQ field with the current interrupt number.
4. During priority sorting, if the IRQ/FIQ is enabled at the host processor side, the host processor automatically saves the current context and executes the ISR as follows.

   The ARM host processor automatically performs the following actions in pseudo code:

```
LR = PC + 4                    /* return link */
SPSR = CPSR                    /* Save CPSR before execution */
CPSR[5] = 0                    /* Execute in ARM state */
CPSR[7] = 1                    /* Disable IRQ */
CPSR[8] = 1                    /* Disable Imprecise Data Aborts */
CPSR[9] = CP15_reg1_EEbit      /* Endianness on exception entry */
if interrupt == IRQ then
CPSR[4:0] = 0b10010            /* Enter IRQ mode */
if high vectors configured then
PC = 0xFFFF0018
else
PC = 0x00000018                /* execute interrupt vector */
else if interrupt == FIQ then
CPSR[4:0] = 0b10001            /* Enter FIQ mode */
CPSR[6] = 1                    /* Disable FIQ */
if high vectors configured then
PC = 0xFFFF001C
else
PC = 0x0000001C                /* execute interrupt vector */
endif
```

5. The ISR saves the remaining context, identifies the interrupt source by reading the ACTIVEIRQ/ACTIVEFIQ field, and jumps to the relevant subroutine handler as follows:

> **CAUTION**
>
> The code in steps 5 and 7 is an assembly code compatible with ARM architecture V6 and V7. This code is developed for the Texas Instruments Code Composer Studio tool set. It is a draft version, only tested on an emulated environment.

```
 ;INTCPS_SIR_IRQ/INTCPS_SIR_FIQ register address
INTCPS_SIR_IRQ_ADDR/INTCPS_SIR_FIQ_ADDR .word 0x48200040/0x48200044
 ; ACTIVEIRQ bit field mask to get only the bit field
ACTIVEIRQ_MASK .equ 0x7F
_IRQ_ISR/_FIQ_ISR:
 ; Save the critical context
STMFD SP!, {R0-R12, LR} ; Save working registers and the Link register
MRS R11, SPSR ; Save the SPSR into R11
 ; Get the number of the highest priority active IRQ/FIQ
LDR R10, INTCPS_SIR_IRQ_ADDR/INTCPS_SIR_FIQ_ADDR
LDR R10, [R10] ; Get the INTCPS_SIR_IRQ/INTCPS_SIR_FIQ register
AND R10, R10, #ACTIVEIRQ_MASK ; Apply the mask to get the active IRQ number
 ; Jump to relevant subroutine handler
LDR PC, [PC, R10, lsl #2] ; PC base address points this instruction + 8
NOP ; To index the table by the PC
 ; Table of handler start addresses
.word IRQ0handler ;For IRQ0 of BANK0
.word IRQ1handler
.word IRQ2handler
```

6. The subroutine handler executes code specific to the peripheral generating the interrupt by handling the event and deasserting the interrupt condition at the peripheral side.

```
 ; IRQ0 subroutine
IRQ0handler:
 ; Save working registers
STMFD SP!, {R0-R1}
 ; Now read-modify-write the peripheral module status register
 ; to de-assert the M_IRQ_0 interrupt signal
 ; De-Assert the peripheral interrupt
MOV R0, #0x7 ; Mask for 3 flags
LDR R1, MODULE0_STATUS_REG_ADDR ; Get the address of the module Status Register
STR R0, [R1] ; Clear the 3 flags
 ; Restore working registers LDMFD SP!, {R0-R1}
 ; Jump to the end part of the ISR
B IRQ_ISR_end/FIQ_ISR_end
```

Copyright © 2011, Texas Instruments Incorporated

7. After the return of the subroutine, the ISR sets the NEWIRQAGR/NEWFIQAGR bit to enable the processing of subsequent pending IRQs/FIQs and to restore ARM context in the following code. Because the writes are posted on an Interconnect bus, to be sure that the preceding writes are done before enabling IRQs/FIQs, a Data Synchronization Barrier is used. This operation ensure that the IRQ/FIQ line is de-asserted before IRQ/FIQ enabling. After that, the INTC processes any other pending interrupts or deasserts the IRQ/FIQ signal if there is no interrupt.

```
 ; INTCPS_CONTROL register address
INTCPS_CONTROL_ADDR .word 0x48200048;
NEWIRQAGR/NEWFIQAGR bit mask to set only the NEWIRQAGR/NEWFIQAGR bit
NEWIRQAGR_MASK/NEWFIQAGR_MASK .equ 0x01/0x02
IRQ_ISR_end/FIQ_ISR_end:
 ; Allow new IRQs/FIQs at INTC side
 ; The INTCPS_CONTROL register is a write only register so no need to write back others bits
MOV R0, #NEWIRQAGR_MASK/NEWFIQAGR_MASK ; Get the NEWIRQAGR/NEWFIQAGR bit position
LDR R1, INTCPS_CONTROL_ADDR
STR R0, [R1] ; Write the NEWIRQAGR/NEWFIQAGR bit to allow new IRQs/FIQ
 ; Data Synchronization Barrier MOV R0, #0
MCR P15, #0, R0, C7, C10, #4
 ; restore critical context
MSR SPSR, R11 ; Restore the SPSR from R11
LDMFD SP!, {R0-R12, LR} ; Restore working registers and  Link register
 ; Return after handling the interrupt
SUBS PC, LR, #4
8. After the ISR return, the ARM automatically restores its context as follows:
CPSR = SPSR
PC = LR
```

Figure 6-2 shows the IRQ/FIQ processing sequence from the originating device peripheral module to the main program interruption.

The priority sorting mechanism is frozen during an interrupt processing sequence. If an interrupt condition occurs during this time, the interrupt is not lost. It is sorted when the NEWIRQAGR/NEWFIQAGR bit is set (priority sorting is reactivated).

6.1.6.3 INTC Preemptive Processing Sequence

Preemptive interrupts, also called nested interrupts, can reduce the latencies for higher priority interrupts. A preemptive ISR can be suspended by a higher priority interrupt. Thus, the higher priority interrupt can be served immediately. Nested interrupts must be used carefully to avoid using corrupted data. Programmers must save corruptible registers and enable IRQ or FIQ at ARM side. IRQ and FIQ processing sequences are quite similar, the differences for the FIQ sequence are shown after a '/' character in the code below.

To enable IRQ/FIQ preemption by higher priority IRQs/FIQs, programers can follow this procedure to write the ISR.

At the beginning of an IRQ/FIQ ISR:

1. Save the ARM critical context registers.
2. Save the INTCPS_THRESHOLD PRIORITYTHRESHOLD field before modifying it.
3. Read the active interrupt priority in the INTCPS_IRQ_PRIORITY IRQPRIORITY/INTCPS_FIQ_PRIORITY FIQPRIORITY field and write it to the PRIORITYTHRESHOLD(1) field.
4. Read the active interrupt number in the INTCPS_SIR_IRQ[6:0] ACTIVEIRQ/INTCPS_SIR_FIQ[6:0] ACTIVEFIQ field to identify the interrupt source.
5. Write 1 to the appropriate INTCPS_CONTROL NEWIRQAGR and (2) NEWFIQAGR bit while an interrupt is still processing to allow only higher priority interrupts to preempt.
6. Because the writes are posted on an Interconnect bus, to be sure that the preceding writes are done before enabling IRQs/FIQs, a Data Synchronization Barrier is used. This operation ensure that the IRQ line is de-asserted before IRQ/FIQ enabling.
7. Enable IRQ/FIQ at ARM side.
8. Jump to the relevant subroutine handler.

The following sample code shows the previous steps:

CAUTION

The following code is an assembly code compatible with ARM architecture V6 and V7. This code is developed for the Texas Instruments Code Composer Studio tool set. It is a draft version, only tested on an emulated environment.

```
 ; bit field mask to get only the bit field
ACTIVEPRIO_MASK .equ 0x7F
_IRQ_ISR:
 ; Step 1 : Save the critical context
STMFD SP!, {R0-R12, LR} ; Save working registers
MRS R11, SPSR ; Save the SPSR into R11
 ; Step 2 : Save the INTCPS_THRESHOLD register into R12
LDR R0, INTCPS_THRESHOLD_ADDR
LDR R12, [R0]
(1) The priority-threshold mechanism is enabled automatically when writing a priority in the
range of 0x00 to 0x7F. Writing a value of 0xFF (reset default) disables the priority-threshold
mechanism. Values between 0x3F and 0xFF must not be used. When the hardware-priority threshold is
in use, the priorities of interrupts selected as FIQ or IRQ become linked otherwise, they are
independent. When they are linked, all FIQ priorities must be set higher than all IRQ priorities
to maintain the relative priority of FIQ over IRQ.
(2) When handling FIQs using the priority-threshold mechanism, both NEWFIQAGR and NEWIRQAGR bits
must be written at the same time to ensure that the new priority threshold is applied while an
IRQ sort is in progress. This IRQ will not have been seen by the ARM, as it will have been masked
on entry to the FIQ ISR. However, the source of the IRQ remains active and it is finally
processed when the priority threshold falls to a priority sufficiently low to allow it to be
processed. The precaution of writing to New FIQ Agreement is not required during an IRQ ISR, as
FIQ sorting is not affected (provided all FIQ priorities are higher than all IRQ priorities).
 ; Step 3 : Get the priority of the highest priority active IRQ
LDR R1, INTCPS_IRQ_PRIORITY_ADDR/INTCPS_FIQ_PRIORITY_ADDR
LDR R1, [R1] ; Get the INTCPS_IRQ_PRIORITY/INTCPS_FIQ_PRIORITY register
AND R1, R1, #ACTIVEPRIO_MASK ; Apply the mask to get the priority of the IRQ
STR R1, [R0] ; Write it to the INTCPS_THRESHOLD register
 ; Step 4 : Get the number of the highest priority active IRQ
LDR R10, INTCPS_SIR_IRQ_ADDR/INTCPS_SIR_FIQ_ADDR
LDR R10, [R10] ; Get the INTCPS_SIR_IRQ/INTCPS_SIR_FIQ register
AND R10, R10, #ACTIVEIRQ_MASK ; Apply the mask to get the active IRQ number
 ; Step 5 : Allow new IRQs and FIQs at INTC side
MOV R0, #0x1/0x3 ; Get the NEWIRQAGR and NEWFIQAGR bit position
LDR R1, INTCPS_CONTROL_ADDR
STR R0, [R1] ; Write the NEWIRQAGR and NEWFIQAGR bit
 ; Step 6 : Data Synchronization Barrier
MOV R0, #0 MCR P15, #0, R0, C7, C10, #4
 ; Step 7 : Read-modify-write the CPSR to enable IRQs/FIQs at ARM side
MRS R0, CPSR ; Read the status register
BIC R0, R0, #0x80/0x40 ; Clear the I/F bit
MSR CPSR, R0 ; Write it back to enable IRQs
 ; Step 8 : Jump to relevant subroutine handler
LDR PC, [PC, R10, lsl #2] ; PC base address points this instruction + 8
NOP ; To index the table by the PC
 ; Table of handler start addresses
.word IRQ0handler ;IRQ0 BANK0
.word IRQ1handler
.word IRQ2handler
```

Copyright © 2011, Texas Instruments Incorporated

After the return of the relevant IRQ/FIQ subroutine handle:

1. Disable IRQs/FIQs at ARM side.
2. Restore the INTCPS_THRESHOLD PRIORITYTHRESHOLD field.
3. Restore the ARM critical context registers.

The following sample code shows the three previous steps:

CAUTION

The following code is an assembly code compatible with ARM architecture V6 and V7. This code is developed for the Texas Instruments Code Composer Studio tool set. It is a draft version, only tested on an emulated environment.

```
IRQ_ISR_end:
 ; Step 1 : Read-modify-write the CPSR to disable IRQs/FIQs at ARM side
MRS R0, CPSR ; Read the CPSR
ORR R0, R0, #0x80/0x40 ; Set the I/F bit
MSR CPSR, R0 ; Write it back to disable IRQs
 ; Step 2 : Restore the INTCPS_THRESHOLD register from R12
LDR R0, INTCPS_THRESHOLD_ADDR
STR R12, [R0]
 ; Step 3 : Restore critical context
MSR SPSR, R11 ; Restore the SPSR from R11
LDMFD SP!, {R0-R12, LR} ; Restore working registers and Link register
 ; Return after handling the interrupt
SUBS PC, LR, #4
```

Figure 6-3 shows the nested IRQ/FIQ processing sequence from the originating device peripheral module to the main program interruption.

6.1.6.4 Interrupt Preemption

If wanting to enable pre-emption by higher priority interrupts, the ISR should read the active interrupt priority and write it to the priority threshold register. Writing a '1' to the appropriate NEW_IRQ_AGR or NEW_FIQ_AGR bits of the CONTROL register while still processing the interrupt will now allow only higher priority interrupts to pre-empt.

For each level of pre-emption, the programmer must save the threshold value before modifying it and restore it at the end of that ISR level.

The priority threshold mechanism is enabled automatically when writing a priority in the range of 0 to 7Fh as will be read from the IRQ_PRIORITY and FIQ_PRIORITY registers. Writing a value of FFh (reset default) disables the priority threshold mechanism.

When the hardware priority threshold is in use the priorities of interrupts selected as FIQ or IRQ become linked, otherwise they are independent. When linked, it is required that all FIQ priorities be set higher than all IRQ priorities to maintain the relative priority of FIQ over IRQ.

When handling FIQs using the priority threshold mechanism, it is required to write both New FIQ Agreement and New IRQ Agreement bits at the same time to cover the case that the new priority threshold is applied while an IRQ sorting is in progress. This IRQ will not have been seen by the ARM as it will have been masked on entry to the FIQ ISR. However, the source of the IRQ will remain active and it will be finally processed when the priority threshold falls to a low enough priority. The precaution of writing to New FIQ Agreement (as well as New IRQ Agreement) is not required during an IRQ ISR as FIQ sorting will not be affected (provided all FIQ priorities are higher than all IRQ priorities).

6.1.6.5 ARM A8 INTC Spurious Interrupt Handling

The spurious flag indicates whether the result of the sorting (a window of 10 INTC functional clock cycles after the interrupt assertion) is invalid. The sorting is invalid if:

- The interrupt that triggered the sorting is no longer active during the sorting.
- A change in the mask has affected the result during the sorting time.

As a result, the values in the INTCPS_MIRn, INTCPS_ILRm, or INTCPS_MIR_SETn registers must not be changed while the corresponding interrupt is asserted. Only the active interrupt input that triggered the sort can be masked before it turn on the sort. If these registers are changed within the 10-cycle window after the interrupt assertion. The resulting values of the following registers become invalid:

- INTCPS_SIR_IRQ
- INTCPS_SIR_FIQ
- INTCPS_IRQ_PRIORITY
- INTCPS_FIQ_PRIORITY

This condition is detected for both IRQ and FIQ, and the invalid status is flagged across the SPURIOUSIRQFLAG (see NOTE 1) and SPURIOUSFIQFLAG (see NOTE 2) bit fields in the SIR and PRIORITY registers. A 0 indicates valid and a 1 indicates invalid interrupt number and priority. The invalid indication can be tested in software as a false register value.

NOTE:

1. The INTCPS_SIR_IRQ[31:7] SPURIOUSIRQFLAG bit field is a copy of the INTCPS_IRQ_PRIORITY[31:7] SPURIOUSIRQFLAG bit field.
2. The INTCPS_SIR_FIQ[31:7] SPURIOUSFIQFLAG bit field is a copy of the INTCPS_FIQ_PRIORITY[31:7] SPURIOUSFIQFLAG bit field.

6.6 INTC Registers

Table 6-5 lists the memory-mapped registers for the INTC. All register offset addresses not listed in Table 6-5 should be considered as reserved locations and the register contents should not be modified.

Copyright © 2011, Texas Instruments Incorporated

Table 6-5. INTC REGISTERS

Offset	Acronym	Register Description	Section
0h	INTC_REVISION	This register contains the IP revision code	Section 6.6.1
10h	INTC_SYSCONFIG	This register controls the various parameters of the OCP interface	Section 6.6.2
14h	INTC_SYSSTATUS	This register provides status information about the module	Section 6.6.3
40h	INTC_SIR_IRQ	This register supplies the currently active IRQ interrupt number.	Section 6.6.4
44h	INTC_SIR_FIQ	This register supplies the currently active FIQ interrupt number	Section 6.6.5
48h	INTC_CONTROL	This register contains the new interrupt agreement bits	Section 6.6.6
4Ch	INTC_PROTECTION	This register controls protection of the other registers. This register can only be accessed in priviledged mode, regardless of the curent value of the protection bit.	Section 6.6.7
50h	INTC_IDLE	This register controls the clock auto-idle for the functional clock and the input synchronisers	Section 6.6.8
60h	INTC_IRQ_PRIORITY	This register supplies the currently active IRQ priority level	Section 6.6.9
64h	INTC_FIQ_PRIORITY	This register supplies the currently active FIQ priority level	Section 6.6.10
68h	INTC_THRESHOLD	This register sets the priority threshold	Section 6.6.11
80h	INTC_ITR0	This register shows the raw interrupt input status before masking	Section 6.6.12
84h	INTC_MIR0	This register contains the interrupt mask	Section 6.6.13
88h	INTC_MIR_CLEAR0	This register is used to clear the interrupt mask bits.	Section 6.6.14
8Ch	INTC_MIR_SET0	This register is used to set the interrupt mask bits.	Section 6.6.15
90h	INTC_ISR_SET0	This register is used to set the software interrupt bits. It is also used to read the currently active software interrupts.	Section 6.6.16
94h	INTC_ISR_CLEAR0	This register is used to clear the software interrupt bits	Section 6.6.17
98h	INTC_PENDING_IRQ0	This register contains the IRQ status after masking	Section 6.6.18
9Ch	INTC_PENDING_FIQ0	This register contains the FIQ status after masking	Section 6.6.19
A0h	INTC_ITR1	This register shows the raw interrupt input status before masking	Section 6.6.20
A4h	INTC_MIR1	This register contains the interrupt mask	Section 6.6.21
A8h	INTC_MIR_CLEAR1	This register is used to clear the interrupt mask bits.	Section 6.6.22
ACh	INTC_MIR_SET1	This register is used to set the interrupt mask bits.	Section 6.6.23
B0h	INTC_ISR_SET1	This register is used to set the software interrupt bits. It is also used to read the currently active software interrupts.	Section 6.6.24
B4h	INTC_ISR_CLEAR1	This register is used to clear the software interrupt bits	Section 6.6.25
B8h	INTC_PENDING_IRQ1	This register contains the IRQ status after masking	Section 6.6.26
BCh	INTC_PENDING_FIQ1	This register contains the FIQ status after masking	Section 6.6.27
C0h	INTC_ITR2	This register shows the raw interrupt input status before masking	Section 6.6.28
C4h	INTC_MIR2	This register contains the interrupt mask	Section 6.6.29
C8h	INTC_MIR_CLEAR2	This register is used to clear the interrupt mask bits.	Section 6.6.30
CCh	INTC_MIR_SET2	This register is used to set the interrupt mask bits.	Section 6.6.31
D0h	INTC_ISR_SET2	This register is used to set the software interrupt bits. It is also used to read the currently active software interrupts.	Section 6.6.32
D4h	INTC_ISR_CLEAR2	This register is used to clear the software interrupt bits	Section 6.6.33
D8h	INTC_PENDING_IRQ2	This register contains the IRQ status after masking	Section 6.6.34
DCh	INTC_PENDING_FIQ2	This register contains the FIQ status after masking	Section 6.6.35

Copyright © 2011, Texas Instruments Incorporated

Table 6-5. INTC REGISTERS (continued)

Offset	Acronym	Register Description	Section
E0h	INTC_ITR3	This register shows the raw interrupt input status before masking	Section 6.6.36
E4h	INTC_MIR3	This register contains the interrupt mask	Section 6.6.37
E8h	INTC_MIR_CLEAR3	This register is used to clear the interrupt mask bits.	Section 6.6.38
ECh	INTC_MIR_SET3	This register is used to set the interrupt mask bits.	Section 6.6.39
F0h	INTC_ISR_SET3	This register is used to set the software interrupt bits. It is also used to read the currently active software interrupts.	Section 6.6.40
F4h	INTC_ISR_CLEAR3	This register is used to clear the software interrupt bits	Section 6.6.41
F8h	INTC_PENDING_IRQ3	This register contains the IRQ status after masking	Section 6.6.42
FCh	INTC_PENDING_FIQ3	This register contains the FIQ status after masking	Section 6.6.43
100h	INTC_ILR0	These registers contain the priority for the interrupts and the FIQ/IRQ steering.	Section 6.6.44
104h	INTC_ILR1	These registers contain the priority for the interrupts and the FIQ/IRQ steering.	Section 6.6.45
108h	INTC_ILR2	These registers contain the priority for the interrupts and the FIQ/IRQ steering.	Section 6.6.46

6.6.2 INTC_SYSCONFIG Register (offset = 10h) [reset = 0h]

This register controls the various parameters of the OCP interface

INTC_SYSCONFIG is shown in Figure 6-5 and described in Table 6-7.

Figure 6-5. INTC_SYSCONFIG Register

Table 6-7. INTC_SYSCONFIG Register Field Descriptions

Bit	Field	Type	Reset	Description
4-3	Reserved	R	0h	
1	SoftReset	R/W		Software reset. Set this bit to trigger a module reset. The bit is automatically reset by the hardware. During reads, it always returns 0. 0 - nofun_w: no functional effect 0 - always_r: Always returns 0 1 - rstMode_w: The module is reset 1 - never_r: never happens
0	Autoidle	R/W		Internal OCP clock gating strategy 0 - clkfree: OCP clock is free running 1 - autoClkGate: Automatic OCP clock gating strategy is applied, bnased on the OCP interface activity

Copyright © 2011, Texas Instruments Incorporated

6.6.3 INTC_SYSSTATUS Register (offset = 14h) [reset = 0h]

This register provides status information about the module

INTC_SYSSTATUS is shown in Figure 6-6 and described in Table 6-8.

6.6.4 INTC_SIR_IRQ Register (offset = 40h) [reset = 0h]

This register supplies the currently active IRQ interrupt number.

INTC_SIR_IRQ is shown in Figure 6-7 and described in Table 6-9.

Bit	Field	Type	Reset	Description
31-2	Reserved	R	0h	
1	NewFIQAgr	W		Reset FIQ output and enable new FIQ generation 0 - nofun_w: no function effect 1 - NewFiq_w: Reset FIQ output and enable new FIQ generation
0	NewIRQAgr	W		New IRQ generation 0 - nofun_w: no function effect 1 - NewIrq_w: Reset IRQ output and enable new IRQ generation

Copyright © 2011, Texas Instruments Incorporated

6.6.7 INTC_PROTECTION Register (offset = 4Ch) [reset = 0h]

This register controls protection of the other registers. This register can only be accessed in priviledged mode, regardless of the curent value of the protection bit.

INTC_PROTECTION is shown in Figure 6-10 and described in Table 6-12.

Figure 6-10. INTC_PROTECTION Register

Bit	Field	Type	Reset	Description
31-1	Reserved	R	0h	
0	Protection	R/W		Protection mode 0 - ProtMDis: Protection mode disabled (default) 1 - ProtMEnb: Protection mode enabled. When enabled, only priviledged mode can access registers.

Copyright © 2011, Texas Instruments Incorporated

6.6.8 INTC_IDLE Register (offset = 50h) [reset = 0h]

This register controls the clock auto-idle for the functional clock and the input synchronisers

INTC_IDLE is shown in Figure 6-11 and described in Table 6-13.

Figure 6-11. INTC_IDLE Register

7.1 GPMC

7.1.1 Introduction

The general-purpose memory controller (GPMC) is an unified memory controller dedicated to interfacing external memory devices:

- Asynchronous SRAM-like memories and application-specific integrated circuit (ASIC) devices
- Asynchronous, synchronous, and page mode (only available in non-multiplexed mode) burst NOR flash devices
- NAND Flash
- Pseudo-SRAM devices

7.1.1.1 GPMC Features

The general features of the GPMC module include:

- Data path to external memory device can be 16- or 8-bit wide
- 32-bit OCPIP 2.0 compliant core, single slave interface. Support non-wrapping and wrapping burst up to 16x32bits.
- Up to 100 MHz external memory clock performance (single device)
- Support for the following memory types:
  - External asynchronous or synchronous 8-bit width memory or device (non burst device)
  - External asynchronous or synchronous 16-bit width memory or device
  - External 16-bit non-multiplexed NOR Flash device
  - External 16-bit address and data multiplexed NOR Flash device
  - External 8-bit and 16-bit NAND flash device
  - External 16-bit pSRAM device
- Up to 16-bit ECC support for NAND flash using BCH code (t=4, 8 or 16) or Hamming code for 8-bit or 16-bit NAND-flash, organized with page size of 512 bytes, 1K bytes, or more.
- Support 512M Bytes maximum addressing capability which can be divided into seven independent chip-select with programmable bank size and base address on 16M Bytes, 32M Bytes, 64M Bytes, or 128M Bytes boundary
- Fully pipelined operation for optimal memory bandwidth usage
- Support external device clock frequency of 1, 2, 3 and 4 divider from L3 clock.
- Support programmable auto-clock gating when there is no access.
- Support Midlereq/SidleAck protocol
- Support the following interface protocols when communicating with external memory or external devices.
  - Asynchronous read/write access
  - Asynchronous read page access (4-8-16 Word16)
  - Synchronous read/write access
  - Synchronous read burst access without wrap capability (4-8-16 Word16)
  - Synchronous read burst access with wrap capability (4-8-16 Word16)
- Address and Data multiplexed access
- Each chip-select as independent and programmable control signal timing parameters for Setup and Hold time. Parameters are set according to the memory device timing parameters, with one L3 clock cycle timing granularity.
- Flexible internal access time control (wait state) and flexible handshake mode using external WAIT pins monitoring (up to two WAIT pins)
- Support bus keeping
- Support bus turn around

Copyright © 2011, Texas Instruments Incorporated

- Pre-fetch and write posting engine associated with system DMA to get full performance from NAND device with minimum impact on NOR/SRAM concurrent access.
- On the fly ECC Hamming Code calculation to improve NAND usage reliability with minimum impact on SW

7.1.1.2 Block Diagram

The GPMC can access various external devices through the L3 Slow Interconnect. The flexible programming model allows a wide range of attached device types and access schemes. Based on the programmed configuration bit fields stored in the GPMC registers, the GPMC is able to generate all control signals timing depending on the attached device and access type. Given the chip-select decoding and its associated configuration registers, the GPMC selects the appropriate device type control signals timing.

Figure 7-1 shows the GPMC functional block diagram. The GPMC consists of six blocks:

- Interconnect port interface
- Address decoder, GPMC configuration, and chip-select configuration register file
- Access engine
- Prefetch and write-posting engine
- Error correction code engine (ECC)
- External device/memory port interface

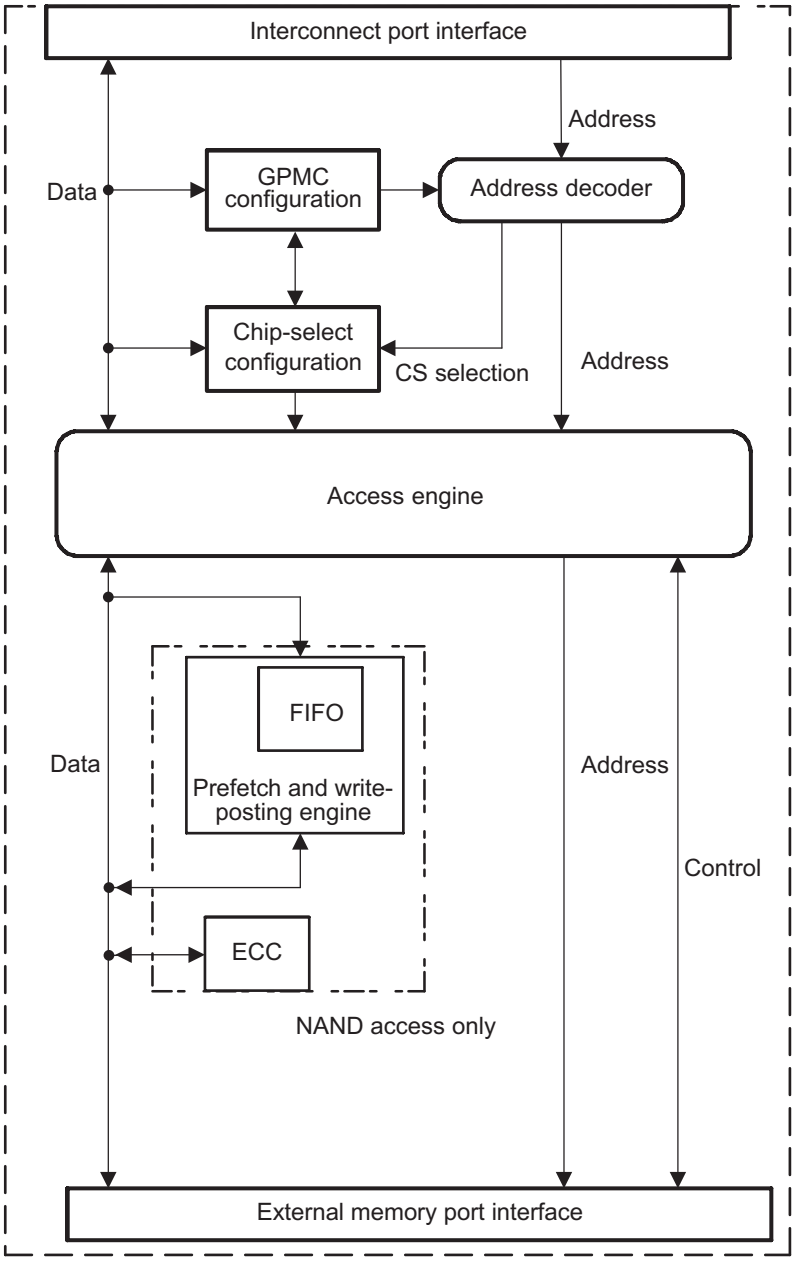
Figure 7-1. GPMC Block Diagram



7.1.1.3 Unsupported GPMC Features

The following module features are not supported in this device.

Table 7-1. Unsupported GPMC Features

Feature	Reason
Chip Select 7	Not pinned out
32-bit devices	Only 16 data lines pinned out
WAIT[3:2]	Not pinned out. All CS regions must use WAIT0 or WAIT1

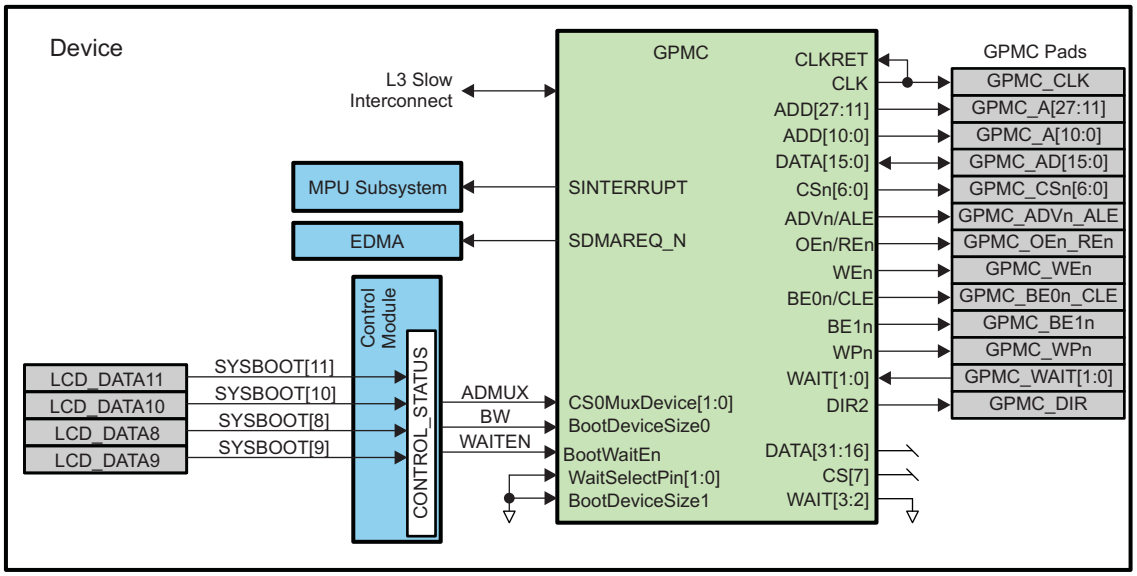
Copyright © 2011, Texas Instruments Incorporated

Copyright © 2011, Texas Instruments Incorporated

7.1.2 Integration

An instantiation of GPMC provides this device with access to NAND Flash, NOR Flash, and other asynchronous and synchronous interface peripherals. Figure 7-2 shows the integration of the GPMC module in this device.

Figure 7-2. GPMC Integration



7.1.2.1 GPMC Connectivity Attributes

The general connectivity attributes for the GPMC module are shown in Table 7-2.

Table 7-2. GPMC Connectivity Attributes

Attributes	Type
Power Domain	Peripheral Domain
Clock Domain	PD_PER_L3S_GCLK
Reset Signals	PER_DOM_RST_N
Idle/Wakeup Signals	Smart Idle
Interrupt Requests	1 interrupt to MPU Subsystem (GPMCINT)
DMA Requests	1 DMA request to EDMA (GPMCEVT)
Physical Address	L3 Slow Slave Port Memory and control register regions qualified with MAddressSpace bit

7.1.2.2 GPMC Clock and Reset Management

The GPMC is a synchronous design and operates from the same clock as the Slow L3. All timings use this clock as a reference.

Table 7-3. GPMC Clock Signals

Clock Signal	Max Freq	Reference / Source	Comments
prcm_gpmc_clk Interface / Functional clock	100 MHz	CORE_CLKOUTM4 / 2	pd_per_l3s_gclk From PRCM

Copyright © 2011, Texas Instruments Incorporated

7.1.2.3 GPMC Signal List

The GPMC external interface signals are shown in Table 7-4.

Table 7-4. GPMC Signal List

Pin	Type	Description
GPMC_A[27:0]	O	Address outputs
GPMC_AD[15:0]	I/O	Data - multiplexed with Address[16:1] and Address[27:12]
GPMC_CSn[6:0]	O	Chip selects (active low)
GPMC_CLK	O	Synchronous mode clock
GPMC_ADVn_ALE	O	Address Valid or Address Latch Enable depending if NOR or NAND protocol memories are selected.
GPMC_OEn_REn	O	Output Enable (active low). Also used as Read Enable (active low) for NAND protocol memories
GPMC_WEn	O	Write Enable (active low)
GPMC_BE0n_CLE	O	Lower Byte Enable (active low). Also used as Command Latch Enable for NAND protocol memories
GPMC_BE1n	O	Upper Byte Enable (active low)
GPMC_WPn	O	Write Protect (active low)
GPMC_WAIT[1:0]	I	External wait signal for NOR and NAND protocol memories.
GPMC_DIR	O	GPMC.D[15:0] signal direction control Low during transmit (for write access: data OUT from GPMC to memory) High during receive (for read access: data IN from memory to GPMC)

Table 7-5. GPMC Pin Multiplexing Options (continued)

GPMC Signal	Non Multiplexed Address Data 16-Bit Device	Non Multiplexed Address Data 8-Bit Device	Multiplexed Address Data 16-Bit Device	16-Bit NAND Device	8-Bit NAND Device
GPMC_AD[3]	D3	D3	A4/D3	D3	D3
GPMC_AD[2]	D2	D2	A3/D2	D2	D2
GPMC_AD[1]	D1	D1	A2/D1	D1	D1
GPMC_AD[0]	D0	D0	A1/D0	D0	D0

With all device types, the GPMC does not drive unnecessary address lines. They stay at their reset value of 00.

Address mapping supports address/data-multiplexed 16-bit wide devices:

- The NOR flash memory controller still supports non-multiplexed address and data memory devices.
- Multiplexing mode can be selected through the GPMC_CONFIG1_i[9-8] MUXADDDATA bit field.
- Asynchronous page mode is not supported for multiplexed address and data devices.

Copyright © 2011, Texas Instruments Incorporated

7.1.3.2 GPMC Modes

This section shows three GPMC external connections options:

- Figure 7-3 shows a connection between the GPMC and a 16-bit synchronous address/data-multiplexed (or AAD-multiplexed, but this protocol use less address pins) external memory device.
- Figure 7-4 shows a connection between the GPMC and a 16-bit synchronous nonmultiplexed external memory device .
- Figure 7-5 shows a connection between the GPMC and a 8-bit NAND device

Figure 7-3. GPMC to 16-Bit Address/Data-Multiplexed Memory

7.1.3.3 GPMC Functional Description

The GPMC basic programming model offers maximum flexibility to support various access protocols for each of the eight configurable chip-selects. Use optimal chip-select settings, based on the characteristics of the external device:

- Different protocols can be selected to support generic asynchronous or synchronous random-access devices (NOR flash, SRAM) or to support specific NAND devices.
- The address and the data bus can be multiplexed on the same external bus.
- Read and write access can be independently defined as asynchronous or synchronous.
- System requests (byte, 16-bit word, burst) are performed through single or multiple accesses. External access profiles (single, multiple with optimized burst length, native- or emulated-wrap) are based on external device characteristics (supported protocol, bus width, data buffer size, native-wrap support).
- System burst read or write requests are synchronous-burst (multiple-read or multiple-write). When neither burst nor page mode is supported by external memory or ASIC devices, system burst read or write requests are translated to successive single synchronous or asynchronous accesses (single reads or single writes). 8-bit wide devices are supported only in single synchronous or single asynchronous read or write mode.
- To simulate a programmable internal-wait state, an external wait pin can be monitored to dynamically control external access at the beginning (initial access time) of and during a burst access.

Each control signal is controlled independently for each chip-select. The internal functional clock of the GPMC (GPMC_FCLK) is used as a time reference to specify the following:

- Read- and write-access duration
- Most GPMC external interface control-signal assertion and deassertion times
- Data-capture time during read access
- External wait-pin monitoring time
- Duration of idle time between accesses, when required

7.1.3.3.1 GPMC Clock Configuration

Table 7-6 describes the GPMC clocks.

Table 7-6. GPMC Clocks

Signal	I/O	Description
GPMC_FCLK	I	Functional and interface clock
GPMC_CLK	O	External clock provided to synchronous external memory devices.

The GPMC_CLK is generated by the GPMC from the internal GPMC_FCLK clock. The source of the GPMC_FCLK is described in . The GPMC_CLK is configured via the GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER field (for i = 0 to 3) as shown in Table 7-7.

Table 7-7. GPMC_CONFIG1_i Configuration

Source Clock	GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER	GPMC_CLK Generated Clock Provided to External Memory Device
GPMC_FCLK	00	GPMC_FCLK
	01	GPMC_FCLK/2
	10	GPMC_FCLK/4
	11	GPMC_FCLK/8

7.1.3.3.2 GPMC Software Reset

The GPMC can be reset by software through the GPMC_SYSCONFIG[1] SOFTRESET bit. Setting the bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. Hardware and software resets initialize all GPMC registers and the finite state-machine (FSM) immediately and unconditionally. The GPMC_SYSSTATUS[0] RESETDONE bit indicates that the software reset is complete when its value is 1. The software must ensure that the software reset completes before doing GPMC operations.

7.1.3.3.3 GPMC Power Management

GPMC power is supplied by the CORE power domain, and GPMC power management complies with system power-management guidelines. Table 7-8 describes power-management features available for the GPMC module.

Table 7-8. GPMC Local Power Management Features

Feature	Registers	Description
Clock Auto Gating	GPMC_SYSCONFIG[0] AUTOIDLE] bit	This bit allows a local power optimization inside the module, by gating the GPMC_FCLK clock upon the internal activity.
Slave Idle Modes	GPMC_SYSCONFIG[4-3] SIDLEMODE bit field	Force-idle, No-idle and Smart-idle wakeup modes are available
Clock Activity	N/A	Feature not available
Master Standby Modes	N/A	Feature not available
Global Wake-up Enable	N/A	Feature not available
Wake-up Sources Enable	N/A	Feature not available

Copyright © 2011, Texas Instruments Incorporated

7.1.3.3.4 GPMC Interrupt Requests

The GPMC generates one interrupt event as shown in .

- The interrupt request goes from GPMC (GPMC_IRQ) to the Cortex-A8 MPU subsystem: A_IRQ_100

Table 7-9 lists the event flags, and their mask, that can cause module interrupts.

Table 7-9. GPMC Interrupt Events

Event Flag	Event Mask	Sensitivity	Map to	Description
GPMC_IRQSTATUS[9] WAIT1EDGEDETECTIONSTATUS	GPMC_IRQENABLE[9] WAIT1EDGEDETECTIONENABLE	Edge	A_IRQ_100	Wait1 edge detection interrupt: Triggered if a rising or falling edge is detected on the GPMC_WAIT1 signal. The rising or falling edge detection of Wait1 is selected through GPMC_CONFIG[9] WAIT1PINPOLARITY bit.
GPMC_IRQSTATUS[8] WAIT0EDGEDETECTIONSTATUS	GPMC_IRQENABLE[8] WAIT0EDGEDETECTIONENABLE	Edge	A_IRQ_100	Wait0 edge detection interrupt: Triggered if a rising or falling edge is detected on the GPMC_WAIT0 signal. The rising or falling edge detection of Wait0 is selected through GPMC_CONFIG[8] WAIT0PINPOLARITY bit.
GPMC_IRQSTATUS[1] TERMINALCOUNTSTATUS	GPMC_IRQENABLE[1] TERMINALCOUNTENABLE	Level	A_IRQ_100	Terminal count event: Triggered on prefetch process completion, that is when the number of currently remaining data to be requested reaches 0.
GPMC_IRQSTATUS[0] FIFOEVENTSTATUS	GPMC_IRQENABLE[0] FIFOEVENTENABLE	Level	A_IRQ_100	FIFO event interrupt: Indicates FIFO levels availability for in Write-Posting mode and prefetch mode. GPMC_PREFETCH_CONFIG[2] DMAMODE bit shall be cleared to 0.

7.1.3.3.5 GPMC DMA Requests

The GPMC generates one DMA event, from GPMC (GPMC_DMA_REQ) to the eDMA: e_DMA_53

7.1.3.3.6 L3 Slow Interconnect Interface

The GPMC L3 Slow interconnect interface is a pipelined interface including an 16 × 32-bit word write buffer. Any system host can issue external access requests through the GPMC. The device system can issue the following requests through this interface:

- One 8-bit / 16-bit / 32-bit interconnect access (read/write)
- Two incrementing 32-bit interconnect accesses (read/write)
- Two wrapped 32-bit interconnect accesses (read/write)
- Four incrementing 32-bit interconnect accesses (read/write)
- Four wrapped 32-bit interconnect accesses (read/write)
- Eight incrementing 32-bit interconnect accesses (read/write)
- Eight wrapped 32-bit interconnect accesses (read/write)

Only linear burst transactions are supported; interleaved burst transactions are not supported. Only power-of-two-length precise bursts 2 × 32, 4 × 32, 8 × 32 or 16 × 32 with the burst base address aligned on the total burst size are supported (this limitation applies to incrementing bursts only).

This interface also provides one interrupt and one DMA request line, for specific event control.

It is recommended to program the GPMC_CONFIG1_i ATTACHEDDEVICEPAGELENGTH field ([24-23]) according to the effective attached device page length and to enable the GPMC_CONFIG1_i WRAPBURST bit ([31]) if the attached device supports wrapping burst. However, it is possible to emulate wrapping burst on a non-wrapping memory by providing relevant addresses within the page or splitting transactions. Bursts larger than the memory page length are chopped into multiple bursts transactions. Due to the alignment requirements, a page boundary is never crossed.

7.1.3.3.7 GPMC Address and Data Bus

The current application supports GPMC connection to NAND devices and to address/data-multiplexed memories or devices. Connection to address/data-nonmultiplexed memories Depending on the GPMC configuration of each chip-select, address and data bus lines that are not required for a particular access protocol are not updated (changed from current value) and are not sampled when input (input data bus).

- For address/data-multiplexed and AAD-multiplexed NOR devices, the address is multiplexed on the data bus.
- 8-bit wide NOR devices do not use GPMC I/O: GPMC_AD[15-8] for data (they are used for address if needed).
- 16-bit wide NAND devices do not use GPMC I/O: GPMC_A[27-0].
- 8-bit wide NAND devices do not use GPMC I/O: GPMC_A[27-0] and GPMC I/O: GPMC_AD[15-8].

7.1.3.3.7.1 GPMC I/O Configuration Setting

NOTE: In this section and next sections, the i in GPMC_CONFIGx_i stands for the GPMC chip-select i where i = 0 to 6.

To select a NAND device, program the following register fields:

- GPMC_CONFIG1_i[11-10] DEVICETYPE field = 10b
- GPMC_CONFIG1_i[9-8] MUXADDDATA bit = 00

To select an address/data-multiplexed device, program the following register fields:

- GPMC_CONFIG1_i[11-10] DEVICETYPE field = 00
- GPMC_CONFIG1_i[9-8] MUXADDDATA bit = 10b

To select an address/address/data-multiplexed device, program the following register fields:

- GPMC_CONFIG1_i[11-10] DEVICETYPE field = 00
- GPMC_CONFIG1_i[9-8] MUXADDDATA bit = 01b

To select an address/data-nonmultiplexed device , program the following register fields:

- GPMC_CONFIG1_i[11-10] DEVICETYPE field = 00
- GPMC_CONFIG1_i[9-8] MUXADDDATA bit = 00

7.1.3.3.8 Address Decoder and Chip-Select Configuration

Addresses are decoded accordingly with the address request of the chip-select and the content of the chip-select base address register file, which includes a set of global GPMC configuration registers and eight sets of chip-select configuration registers.

The GPMC configuration register file is memory-mapped and can be read or written with byte, 16-bit word, or 32-bit word accesses. The register file should be configured as a noncacheable, nonbufferable region to prevent any desynchronization between host execution (write request) and the completion of register configuration (write completed with register updated). Section 7.1.5 provides the GPMC register locations. For the map of GPMC memory locations, see Table 7-55.

After the chip-select is configured, the access engine accesses the external device, drives the external interface control signals, and applies the interface protocol based on user-defined timing parameters and settings.

Copyright © 2011, Texas Instruments Incorporated

7.1.3.3.8.1 Chip-Select Base Address and Region Size

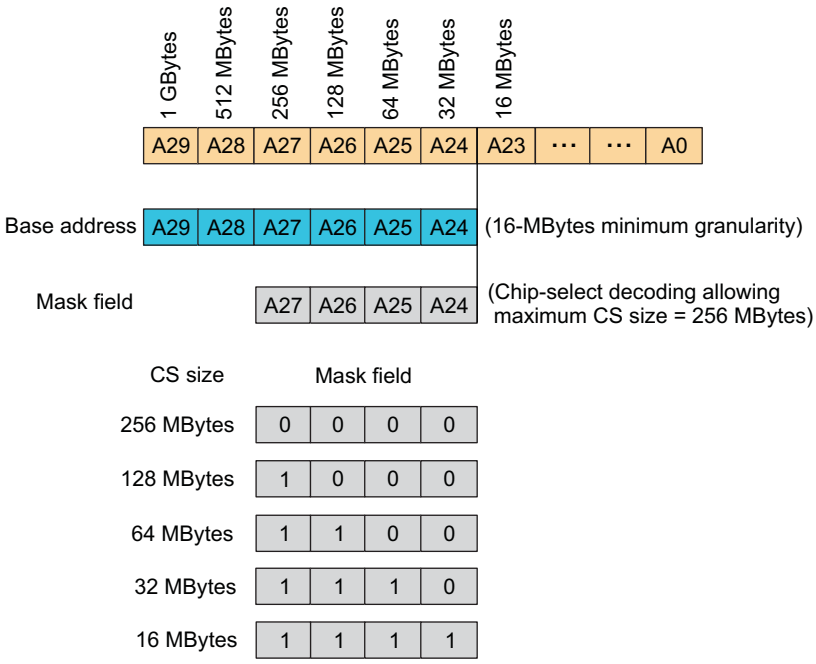
Any external memory or ASIC device attached to the GPMC external interface can be accessed by any device system host within the GPMC 512-Mbyte contiguous address space. For details, see Table 7-55.

The GPMC 512 Mbyte address space can be divided into a maximum of seven chip-select regions with programmable base address and programmable CS size. The CS size is programmable from 16 Mbytes to 256 Mbytes (must be a power-of-2) and is defined by the mask field. Attached memory smaller than the programmed CS region size is accessed through the entire CS region (aliasing).

Each chip-select has a 6-bit base address encoding and a 4-bit decoding mask, which must be programmed according to the following rules:

- The programmed chip-select region base address must be aligned on the chip-select region size address boundary and is limited to a power-of-2 address value. During access decoding, the register base address value is used for address comparison with the address-bit line mapping as described in Figure 7-6 (with A0 as the device system byte-address line). Base address is programmed through the GPMC_CONFIG7_i[5-0] BASEADDRESS bit field.
- The register mask is used to exclude some address lines from the decoding. A register mask bit field cleared to 0 suppresses the associated address line from the address comparison (incoming address bit line is don't care). The register mask value must be limited to the subsequent value, based on the desired chip-select region size. Any other value has an undefined result. When multiple chip-select regions with overlapping addresses are enabled concurrently, access to these chip-select regions is cancelled and a GPMC access error is posted. The mask field is programmed through the GPMC_CONFIG7_i[11-8] MASKADDRESS bit field.

Figure 7-6. Chip-Select Address Mapping and Decoding Mask



A mask value of 0010 or 1001 must be avoided because it will create holes in the chip-select address space.

Chip-select configuration (base and mask address or any protocol and timing settings) must be performed while the associated chip-select is disabled through the GPMC_CONFIG7_i[6] CSVALID bit. In addition, a chip-select configuration can only be disabled if there is no ongoing access to that chip-select. This requires activity monitoring of the prefetch or write-posting engine if the engine is active on the chip-select. Also, the write buffer state must be monitored to wait for any posted write completion to the chip-select.

Copyright © 2011, Texas Instruments Incorporated

Any access attempted to a nonvalid GPMC address region (CSVALID disabled or address decoding outside a valid chip-select region) is not propagated to the external interface and a GPMC access error is posted. In case of chip-selects overlapping, an error is generated and no access will occur on either chip-select. Chip-select 0 is the only chip-select region enabled after either a power-up or a GPMC reset.

Although the GPMC interface can drive up to seven chip-selects, the frequency specified for this interface is for a specific load. If this load is exceeded, the maximum frequency cannot be reached. One solution is to implement a board with buffers, to allow the slowest device to maintain the total load on the lines.

7.1.3.3.8.2 Access Protocol

7.1.3.3.8.2.1 Supported Devices

The access protocol of each chip-select can be independently specified through the GPMC_CONFIG1_i[11-10] DEVICETYPE parameter for:

- Random-access synchronous or asynchronous memory like NOR flash, SRAM
- NAND flash asynchronous devices

For more information about the NAND flash GPMC basic programming model and NAND support, see Section 7.1.3.3.12 and Section 7.1.3.3.12.1.

7.1.3.3.8.2.2 Access Size Adaptation and Device Width

Each chip-select can be independently configured through the GPMC_CONFIG1_i[13-12] DEVICESIZE field to interface with a 16-bit wide device or an 8-bit wide device. System requests with data width greater than the external device data bus width are split into successive accesses according to both the external device data-bus width and little-endian data organization.

The device does not provide the A0 byte address line required for random-byte addressable 8-bit wide device interfacing (for both multiplexed and nonmultiplexed protocol). It limits the use of 8-bit wide device interfacing to byte-alias accesses. This limitation is not applicable to NAND device interfacing (8-bit wide or 16-bit wide devices).

7.1.3.3.8.2.3 Address/Data-Multiplexing Interface

For random synchronous or asynchronous memory interfacing (DEVICETYPE = 0b00), an address- and data-multiplexing protocol can be selected through the GPMC_CONFIG1_i[[9-8] MUXADDDATA bit field. The ADVn signal must be used as the external device address latch control signal. For the associated chip-select configuration, ADVn assertion and deassertion time and OEn assertion time must be set to the appropriate value to meet the address latch setup/hold time requirements of the external device (see).

This address/data-multiplexing interface is not applicable to NAND device interfacing. NAND devices require a specific address, command, and data multiplexing protocol (see Section 7.1.3.3.12).

7.1.3.3.8.3 External Signals

7.1.3.3.8.3.1 WAIT Pin Monitoring Control

GPMC access time can be dynamically controlled using an external gpmc_wait pin when the external device access time is not deterministic and cannot be defined and controlled only using the GPMC internal RDACCESSTIME, WRACCESSTIME and PAGEBURSTACCESSTIME wait state generator.

The GPMC features two input wait pin:gpmc_wait1, and gpmc_wait0. This pin allow control of external devices with different wait-pin polarity. They also allow the overlap of wait-pin assertion from different devices without affecting access to devices for which the wait pin is not asserted.

- The GPMC_CONFIG1_i[17-16] WAITPINSELECT bit field (where i = 0 to 6) selects which input gpmc_wait pin is used for the device attached to the corresponding chip-select.
- The polarity of the wait pin is defined through the WAITxPINPOLARITY bit of the GPMC_CONFIG register. A wait pin configured to be active low means that low level on the WAIT signal indicates that the data is not ready and that the data bus is invalid. When WAIT is inactive, data is valid.

Copyright © 2011, Texas Instruments Incorporated

The GPMC access engine can be configured per CS to monitor the wait pin of the external memory device or not, based on the access type: read or write.

- The GPMC_CONFIG1_i[22] WAITREADMONITORING bit defines whether the wait pin should be monitored during read accesses or not.
- The GPMC_CONFIG1_i[21] WAITWRITEMONITORING bit defines whether the wait pin should be monitored during write accesses or not.

The GPMC access engine can be configured to monitor the wait pin of the external memory device asynchronously or synchronously with the GPMC_CLK clock, depending on the access type: synchronous or asynchronous (the GPMC_CONFIG1_i[29] READTYPE and GPMC_CONFIG1_i[27] WRITETYPE bits).

7.1.3.3.8.3.2 Wait Monitoring During an Asynchronous Read Access

When wait-pin monitoring is enabled for read accesses (WAITREADMONITORING), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the wait-deasserted state.

During asynchronous read accesses with wait-pin monitoring enabled, the wait pin must be at a valid level (asserted or deasserted) for at least two GPMC clock cycles before RDACCESSTIME completes, to ensure correct dynamic access-time control through wait-pin monitoring. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

In this context, RDACCESSTIME is used as a WAIT invalid timing window and is set to such a value that the wait pin is at a valid state two GPMC clock cycles before RDACCESSTIME completes.

Similarly, during a multiple-access cycle (for example, asynchronous read page mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the wait-deasserted state. Wait-monitoring pipelining is also applicable to multiple accesses (access within a page).

- WAIT monitored as active freezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as asserted extends the current access time in the page. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as inactive completes the current access time and starts the next access phase in the page. The data bus is considered valid, and data are captured during this clock cycle. In case of a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their related control timing value and according to the CYCLETIME counter status.

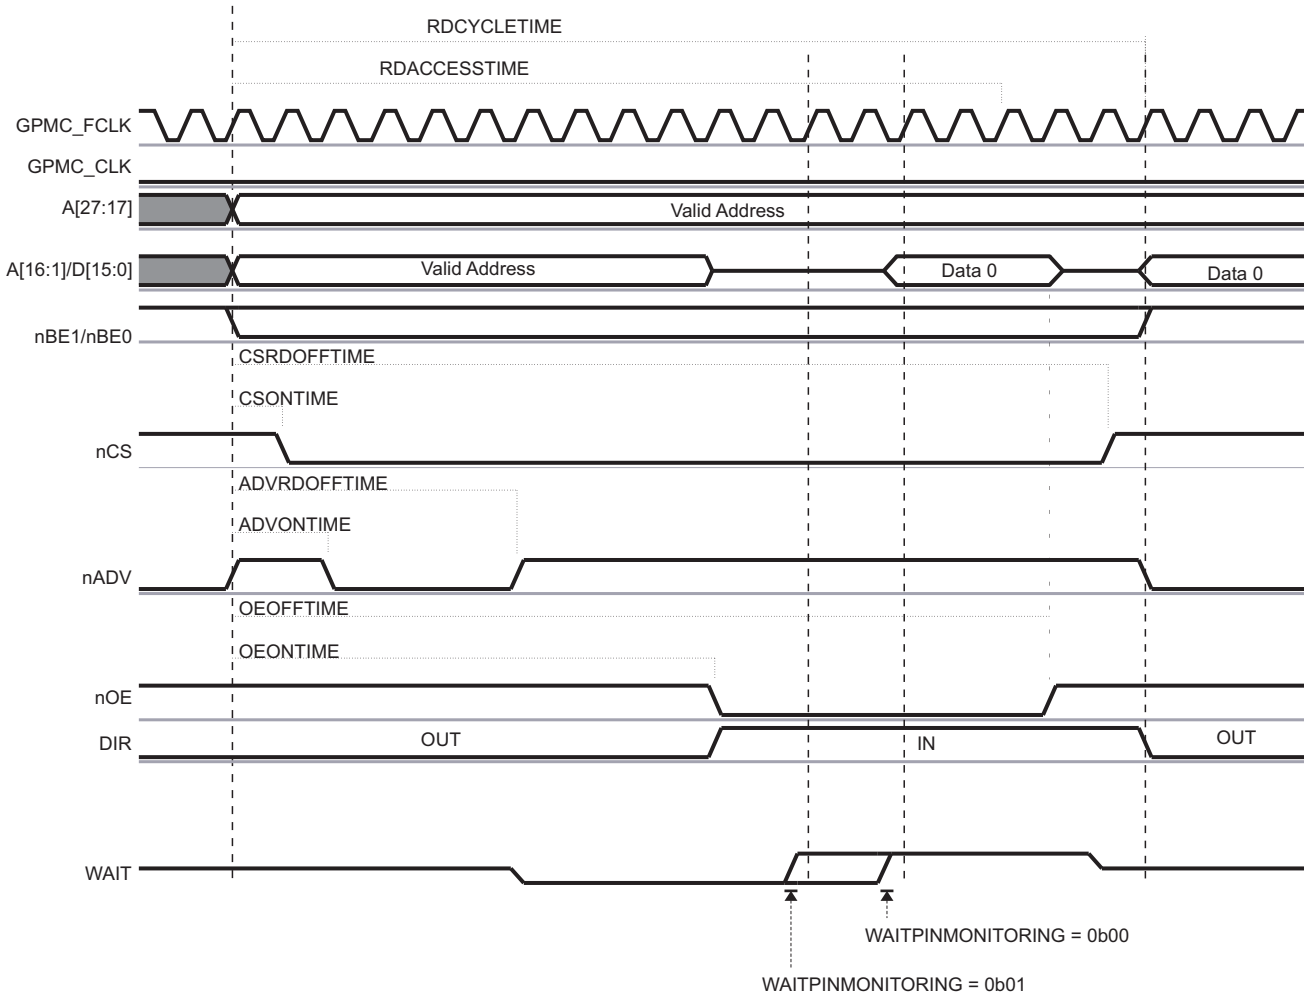
When a delay larger than two GPMC clocks must be observed between wait-pin deactivation time and data valid time (including the required GPMC and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data-capture time and the effective unlock of the CYCLETIME counter. This extra delay can be programmed in the GPMC_CONFIG1_i[19-18] WAITMONITORINGTIME field.

- The WAITMONITORINGTIME parameter does not delay the wait-pin active or inactive detection, nor does it modify the two GPMC clocks pipelined detection delay.
- This extra delay is expressed as a number of GPMC_CLK clock cycles, even though the access is defined as asynchronous, and no GPMC_CLK clock is provided to the external device. Still, GPMCFCLKDIVIDER is used as a divider for the GPMC clock, so it must be programmed to define the correct WAITMONITORINGTIME delay.

Figure 7-7 shows wait behavior during an asynchronous single read access.

Copyright © 2011, Texas Instruments Incorporated

Figure 7-7. Wait Behavior During an Asynchronous Single Read Access (GPMCFCLKDivider = 1)



The WAIT signal is active low. GPMC_CONFIG1_i[19-18] WAITMONITORINGTIME = 00b or 01b.

7.1.3.3.8.3.3 Wait Monitoring During an Asynchronous Write Access

When wait-pin monitoring is enabled for write accesses (GPMC_CONFIG1_i[21] WAITWRITEMONITORING bit = 1), the WAIT-invalid timing window is defined by the WRACCESSTIME field. WRACCESSTIME must be set so that the wait pin is at a valid state two GPMC clock cycles before WRACCESSTIME completes. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

- WAIT monitored as active freezes the CYCLETIME counter. This informs the GPMC that the data bus is not captured by the external device. The control signals are kept in their current state. The data bus still drives the data.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. This informs that the data bus is correctly captured by the external device. All signals, including the data bus, are controlled according to their related control timing value and to the CYCLETIME counter status.

Copyright © 2011, Texas Instruments Incorporated

When a delay larger than two GPMC clock cycles must be observed between wait-pin deassertion time and the effective data write into the external device (including the required GPMC data setup time and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data write time into the external device and the effective unfreezing of the CYCLETIME counter. This extra delay can be programmed in the GPMC_CONFIG1_i[19-18] WAITMONITORINGTIME fields.

- The WAITMONITORINGTIME parameter does not delay the wait-pin assertion or deassertion detection, nor does it modify the two GPMC clock cycles pipelined detection delay.
- This extra delay is expressed as a number of GPMC_CLK clock cycles, even though the access is defined as asynchronous, and even though no clock is provided to the external device. Still, GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER is used as a divider for the GPMC clock and so it must be programmed to define the correct WAITMONITORINGTIME delay.

7.1.3.3.8.3.4 Wait Monitoring During a Synchronous Read Access

During synchronous accesses with wait-pin monitoring enabled, the wait pin is captured synchronously with GPMC_CLK, using the rising edge of this clock.

The WAIT signal can be programmed to apply to the same clock cycle it is captured in. Alternatively, it can be sampled one or two GPMC_CLK cycles ahead of the clock cycle it applies to. This pipelining is applicable to the entire burst access, and to all data phase in the burst access. This WAIT pipelining depth is programmed in the GPMC_CONFIG1_i[19-18] WAITMONITORINGTIME field, and is expressed as a number of GPMC_CLK clock cycles.

In synchronous mode, when wait-pin monitoring is enabled (GPMC_CONFIG1_i[22] WAITREADMONITORING bit), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the WAIT deasserted-state detection.

Depending on the programmed WAITMONITORINGTIME value, the wait pin should be at a valid level, either asserted or deasserted:

- In the same clock cycle the data is valid if WAITMONITORINGTIME = 0 (at RDACCESSTIME completion)
- In the WAITMONITORINGTIME x (GPMCFCLKDIVIDER + 1) GPMC_FCLK clock cycles before RDACCESSTIME completion if WAITMONITORINGTIME not equal to 0

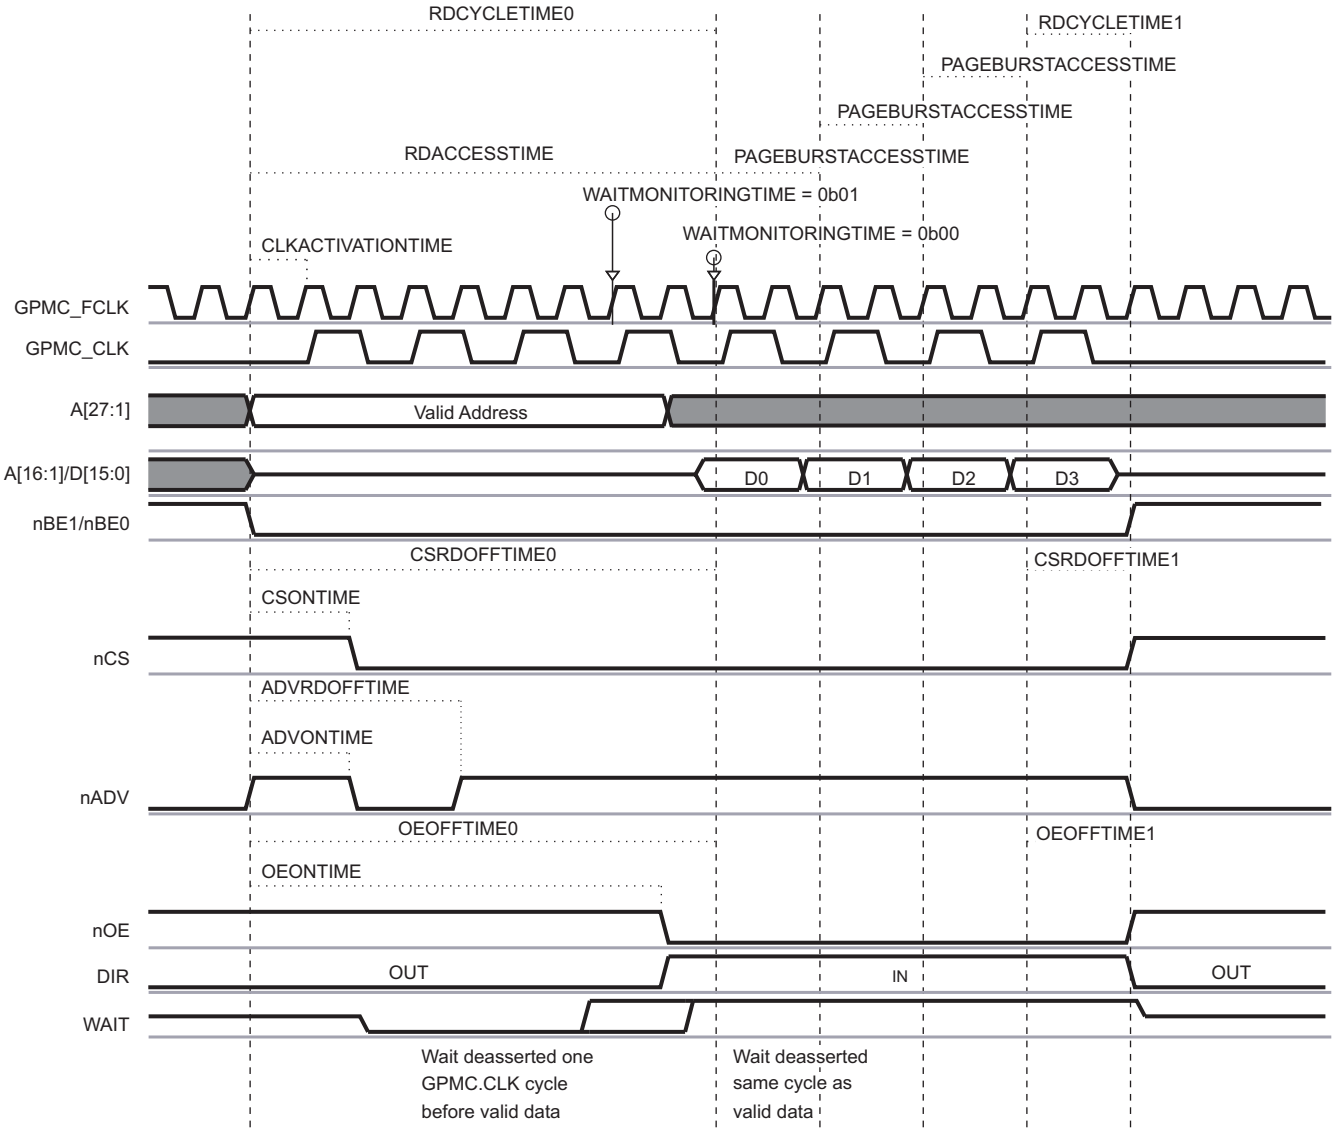
Similarly, during a multiple-access cycle (burst mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the wait-inactive state. The Wait pipelining depth programming applies to the whole burst access.

- WAIT monitored as active freezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in a lock state), WAIT monitored as active extends the current access time in the burst. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in lock state), WAIT monitored as inactive completes the current access time and starts the next access phase in the burst. The data bus is considered valid, and data are captured during this clock cycle. In a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their relative control timing value and the CYCLETIME counter status.

Figure 7-8 shows wait behavior during a synchronous read burst access.

Copyright © 2011, Texas Instruments Incorporated

Figure 7-8. Wait Behavior During a Synchronous Read Burst Access



The WAIT signal is active low. WAITMONITORINGTIME = 00b or 01b.

7.1.3.3.8.3.5 Wait Monitoring During a Synchronous Write Access

During synchronous accesses with wait-pin monitoring enabled (the WAITWRITEMONITORING bit), the wait pin is captured synchronously with GPMC_CLK, using the rising edge of this clock.

If enabled, external wait-pin monitoring can be used in combination with WRACCESSTIME to delay the effective memory device GPMC_CLK capture edge.

Wait-monitoring pipelining depth is similar to synchronous read access:

- At WRACCESSTIME completion if WAITMONITORINGTIME = 0
- In the WAITMONITORINGTIME x (GPMCFCLKDIVIDER + 1) GPMC_FCLK cycles before WRACCESSTIME completion if WAITMONITORINGTIME not equal to 0.

Copyright © 2011, Texas Instruments Incorporated

Wait-monitoring pipelining definition applies to whole burst accesses:

- WAIT monitored as active freezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as active indicates that the data bus is not being captured by the external device. Control signals are kept in their current state. The data bus is kept in its current state.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as inactive indicates the effective data capture of the bus by the external device and starts the next access of the burst. In case of a single access or if this was the last access in a multiple access cycle, all signals, including the data bus, are controlled according to their related control timing value and the CYCLETIME counter status.

Wait monitoring is supported for all configurations except for GPMC_CONFIG1_i[19-18] WAITMONITORINGTIME = 0 for write bursts with a clock divider of 1 or 2 (GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER field equal to 0 or 1, respectively).

7.1.3.3.8.3.6 WAIT With NAND Device

For details about the use of the wait pin for communication with a NAND flash external device, see Section 7.1.3.3.12.2.

7.1.3.3.8.3.7 Idle Cycle Control Between Successive Accesses

7.1.3.3.8.3.7.1 Bus Turnaround (BUSTURNAROUND)

To prevent data-bus contention, an access that follows a read access to a slow memory/device must be delayed (in other words, control the CSn/OEn de-assertion to data bus in high-impedance delay).

The bus turnaround is a time-out counter starting after CSn or OEn de-assertion time, whichever occurs first, and delays the next access start-cycle time. The counter is programmed through the GPMC_CONFIG6_i[3-0] BUSTURNAROUND bit field.

After a read access to a chip-select with a non zero BUSTURNAROUND, the next access is delayed until the BUSTURNAROUND delay completes, if the next access is one of the following:

- A write access to any chip-select (same or different from the chip-select data was read from)
- A read access to a different chip-select from the chip-select data was read access from
- A read or write access to a chip-select associated with an address/data-multiplexed device

Bus keeping starts after bus turnaround completion so that DIR changes from IN to OUT after bus turnaround. The bus will not have enough time to go into high-impedance even though it could be driven with the same value before bus turnaround timing.

BUSTURNAROUND delay runs in parallel with GPMC_CONFIG6_i[3-0] CYCLE2CYCLEDELAY delays. It should be noted that BUSTURNAROUND is a timing parameter for the ending chip-select access while CYCLE2CYCLEDELAY is a timing parameter for the following chip-select access. The effective minimum delay between successive accesses is driven by these delay timing parameters and by the access type of the following access. See Figure 7-9 to Figure 7-11.

Another way to prevent bus contention is to define an earlier CSn or OEn deassertion time for slow devices or to extend the value of RDCYCLETIME. Doing this prevents bus contention, but affects all accesses of this specific chip-select.

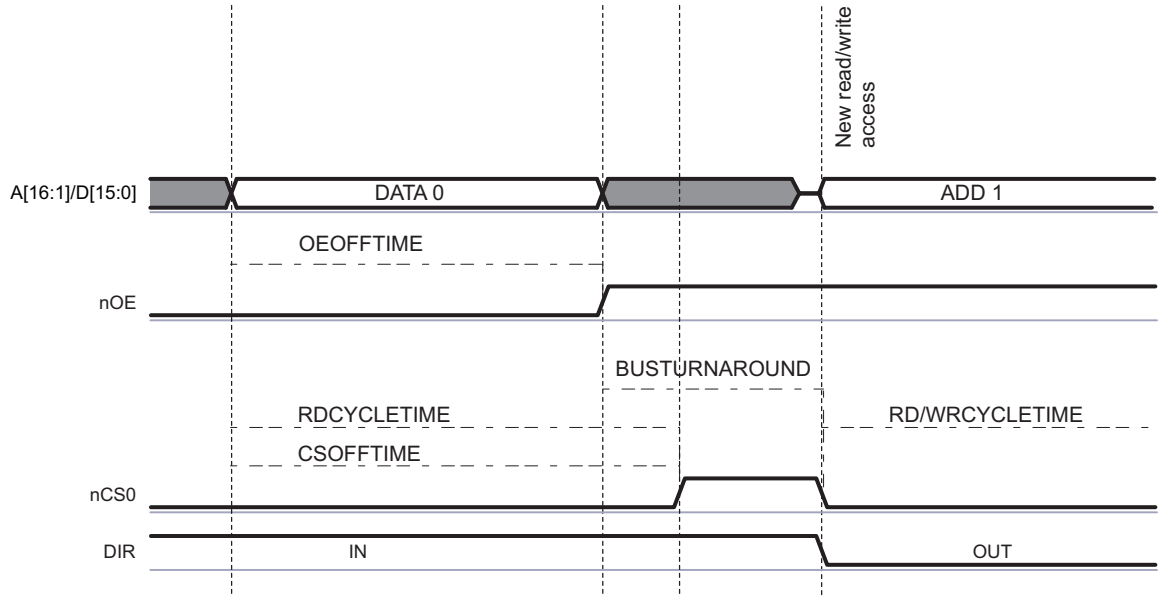
Figure 7-11. Read to Read / Write for a Address-Data or AAD-Multiplexed Device, On Same CS, With Bus Turnaround



7.1.3.3.8.3.7.2 Idle Cycles Between Accesses to Same Chip-Select (CYCLE2CYCLESAMECSEN, CYCLE2CYCLEDELAY)

Some devices require a minimum chip-select signal inactive time between accesses. The GPMC_CONFIG6_i[7] CYCLE2CYCLESAMECSEN bit enables insertion of a minimum number of GPMC_FCLK cycles, defined by the GPMC_CONFIG6_i[11-8] CYCLE2CYCLEDELAY field, between successive accesses of any type (read or write) to the same chip-select.

If CYCLE2CYCLESAMECSEN is enabled, any subsequent access to the same chip-select is delayed until its CYCLE2CYCLEDELAY completes. The CYCLE2CYCLEDELAY counter starts when CSRDOFFTIME/CSWROFFTIME completes.

The same applies to successive accesses occurring during 32-bit word or burst accesses split into successive single accesses when the single-access mode is used (GPMC_CONFIG1_i[30] READMULTIPLE = 0 or GPMC_CONFIG1_i[28] WRITEMULTIPLE = 0).

All control signals are kept in their default states during these idle GPMC_FCLK cycles. This prevents back-to-back accesses to the same chip-select without idle cycles between accesses.

7.1.3.3.8.3.7.3 Idle Cycles Between Accesses to Different Chip-Select (CYCLE2CYCLEDIFFCSEN, CYCLE2CYCLEDELAY)

Because of the pipelined behavior of the system, successive accesses to different chip-selects can occur back-to-back with no idle cycles between accesses. Depending on the control signals (CSn, ADV_ALEn, BE0_CLEn, OE_REn, WEn) assertion and de-assertion timing parameters and on the IC timing parameters, some control signals assertion times may overlap between the successive accesses to different CS. Similarly, some control signals (WEn, OE_REn) may not respect required transition times.

To work around the overlapping and to observe the required control-signal transitions, a minimum of CYCLE2CYCLEDELAY inactive cycles is inserted between the access being initiated to this chip-select and the previous access ending for a different chip-select. This applies to any type of access (read or write).

Copyright © 2011, Texas Instruments Incorporated

If GPMC_CONFIG6_i[6] CYCLE2CYCLEDIFFCSEN is enabled, the chip-select access is delayed until CYCLE2CYCLEDELAY cycles have expired since the end of a previous access to a different chip-select. CYCLE2CYCLEDELAY count starts at CSRDOFFTIME/CSWROFFTIME completion. All control signals are kept inactive during the idle GPMC_FCLK cycles.

CYCLE2CYCLESAMECSEN and CYCLE2CYCLEDIFFCSEN should be set in registers to respectively get idle cycles inserted between accesses on this chip-select and after accesses to a different chip-select.

The CYCLE2CYCLEDELAY delay runs in parallel with the BUSTURNAROUND delay. It should be noted that BUSTURNAROUND is a timing parameter defined for the ending chip-select access, whereas CYCLE2CYCLEDELAY is a timing parameter defined for the starting chip-select access. The effective minimum delay between successive accesses is based on the larger delay timing parameter and on access type combination, since bus turnaround does not apply to all access types. See Section 7.1.3.3.8.3.7.1 for more details on bus turnaround.

Table 7-10 describes the configuration required for idle cycle insertion.

Table 7-10. Idle Cycle Insertion Configuration

First Access Type	BUSTURNAROUND Timing Parameter	Second Access Type	Chip-Select	Addr/Data Multiplexed	CYCLE2CYCLE SAMECSEN Parameter	CYCLE2CYCLE DIFFCSEN Parameter	Idle Cycle Insertion Between the Two Accesses
R/W	0	R/W	Any	Any	0	x	No idle cycles are inserted if the two accesses are well pipelined.
R	>0	R	Same	Nonmuxed	x	0	No idle cycles are inserted if the two accesses are well pipelined.
R	>0	R	Different	Nonmuxed	0	0	BUSTURNAROUND cycles are inserted.
R	>0	R/W	Any	Muxed	0	0	BUSTURNAROUND cycles are inserted.
R	>0	W	Any	Any	0	0	BUSTURNAROUND cycles are inserted.
W	>0	R/W	Any	Any	0	0	No idle cycles are inserted if the two accesses are well pipelined.
R/W	0	R/W	Same	Any	1	x	CYCLE2CYCLEDELAY cycles are inserted.
R/W	0	R/W	Different	Any	x	1	CYCLE2CYCLEDELAY cycles are inserted.
R/W	>0	R/W	Same	Any	1	x	CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is max (BUSTURNAROUND, CYCLE2CYCLEDELAY).
R/W	>0	R/W	Different	Any	x	1	CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is maximum (BUSTURNAROUND, CYCLE2CYCLEDELAY).

Copyright © 2011, Texas Instruments Incorporated

7.1.3.3.8.3.8 Slow Device Support (TIMEPARAGRANULARITY Parameter)

All access-timing parameters can be multiplied by 2 by setting the GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY bit. Increasing all access timing parameters allows support of slow devices.

7.1.3.3.8.3.9 GPMC_DIR Pin

The GPMC_DIR pin is used to control I/O direction on the GPMC data bus GPMC_D[15-0]. Depending on top-level pad multiplexing, this signal can be output and used externally to the device, if required. The GPMC_DIR pin is low during transmit (OUT) and high during receive (IN).

For write accesses, the GPMC_DIR pin stays OUT from start-cycle time to end-cycle time.

For read accesses, the GPMC_DIR pin goes from OUT to IN at OEn assertion time and stays IN until:

- BUSTURNAROUND is enabled
  - The GPMC_DIR pin goes from IN to OUT at end-cycle time plus programmable bus turnaround time.
- BUSTURNAROUND is disabled
  - After an asynchronous read access, the GPMC_DIR pin goes from IN to OUT at RDACCESSTIME + 1 GPMC_FCLK cycle or when RDCYCLETIME completes, whichever occurs last.
  - After a synchronous read access, the GPMC_DIR pin goes from IN to OUT at RDACCESSTIME + 2 GPMC_FCLK cycles or when RDCYCLETIME completes, whichever occurs last.

Because of the bus-keeping feature of the GPMC, after a read or write access and with no other accesses pending, the default value of the GPMC_DIR pin is OUT (see Section 7.1.3.3.9.10). In nonmultiplexed devices, the GPMC_DIR pin stays IN between two successive read accesses to prevent unnecessary toggling.

7.1.3.3.8.3.10 Reset

No reset signal is sent to the external memory device by the GPMC. For more information about external-device reset, see Power, Reset, and Clock Management.

The PRCM module provides an input pin, global_rst_n, to the GPMC:

- The global_rst_n pin is activated during device warm reset and cold reset.
- The global_rst_n pin initializes the internal state-machine and the internal configuration registers.

7.1.3.3.8.3.11 Write Protect Signal (WPn)

When connected to the attached memory device, the write protect signal can enable or disable the lockdown function of the attached memory. The GPMC_WPn output pin value is controlled through the GPMC_CONFIG[4] WRITEPROTECT bit, which is common to all CS.

7.1.3.3.8.3.12 Byte Enable (BE1n/BE0n)

Byte enable signals (BE1n/BE0n) are:

- Valid (asserted or nonasserted according to the incoming system request) from access start to access completion for asynchronous and synchronous single accesses
- Asserted low from access start to access completion for asynchronous and synchronous multiple read accesses
- Valid (asserted or nonasserted, according to the incoming system request) synchronously to each written data for synchronous multiple write accesses

7.1.3.3.8.4 Error Handling

When an error occurs in the GPMC, the error information is stored in the GPMC_ERR_TYPE register and the address of the illegal access is stored in the GPMC_ERR_ADDRESS register. The GPMC keeps only the first error abort information until the GPMC_ERR_TYPE register is reset. Subsequent accesses that cause errors are not logged until the error is cleared by hardware with the GPMC_ERR_TYPE[0]ERRORVALID bit.

Copyright © 2011, Texas Instruments Incorporated

- ERRORNOTSUPPADD occurs when an incoming system request address decoding does not match any valid chip-select region, or if two chip-select regions are defined as overlapped, or if a register file access is tried outside the valid address range of 1KB.
- ERRORNOTSUPPMCMD occurs when an unsupported command request is decoded at the L3 Slow interconnect interface
- ERRORTIMEOUT: A time-out mechanism prevents the system from hanging. The start value of the

9-bit time-out counter is defined in the GPMC_TIMEOUT_CONTROL register and enabled with the GPMC_TIMEOUT_CONTROL[0] TIMEOUTENABLE bit. When enabled, the counter starts at start-cycle time until it reaches 0 and data is not responded to from memory, and then a time-out error occurs. When data are sent from memory, this counter is reset to its start value. With multiple accesses (asynchronous page mode or synchronous burst mode), the counter is reset to its start value for each data access within the burst.

The GPMC does not generate interrupts on these errors. True abort to the MPU or interrupt generation is handled at the interconnect level.

7.1.3.3.9 Timing Setting

The GPMC offers the maximum flexibility to support various access protocols. Most of the timing parameters of the protocol access used by the GPMC to communicate with attached memories or devices are programmable on a chip-select basis. Assertion and deassertion times of control signals are defined to match the attached memory or device timing specifications and to get maximum performance during accesses. For more information on GPMC_CLK and GPMC_FCLK see Section 7.1.3.3.9.6.

In the following sections, the start access time refer to the time at which the access begins.

7.1.3.3.9.1 Read Cycle Time and Write Cycle Time (RDCYCLETIME / WRCYCLETIME)

The GPMC_CONFIG5_i[4-0] RDCYCLETIME and GPMC_CONFIG5_i[12-8] WRCYCLETIME fields define the address bus and byte enables valid times for read and write accesses. To ensure a correct duty cycle of GPMC_CLK between accesses, RDCYCLETIME and WRCYCLETIME are expressed in GPMC_FCLK cycles and must be multiples of the GPMC_CLK cycle. RDCYCLETIME and WRCYCLETIME bit fields can be set with a granularity of 1 or 2 throught GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY.

When either RDCYCLETIME or WRCYCLETIME completes, if they are not already deasserted, all control signals (CSn, ADV_ALEn, OE_REn, WEn, and BE0_CLEn) are deasserted to their reset values, regardless of their deassertion time parameters.

An exception to this forced deassertion occurs when a pipelined request to the same chip-select or to a different chip-select is pending. In such a case, it is not necessary to deassert a control signal with deassertion time parameters equal to the cycle-time parameter. This exception to forced deassertion prevents any unnecessary glitches. This requirement also applies to BE signals, thus avoiding an unnecessary BE glitch transition when pipelining requests.

If no inactive cycles are required between successive accesses to the same or to a different chip-select (GPMC_CONFIG6_i[7] CYCLE2CYCLESAMECSEN = 0 or GPMC_CONFIG6_i[6] CYCLE2CYCLEDIFFCSEN = 0, where i = 0 to 3), and if assertion-time parameters associated with the pipelined access are equal to 0, asserted control signals (CSn, ADV_ALEn, BE0_CLEn, WEn, and OE_REn) are kept asserted. This applies to any read/write to read/write access combination.

If inactive cycles are inserted between successive accesses, that is, CYCLE2CYCLESAMECSEN = 1 or CYCLE2CYCLEDIFFCSEN = 1, the control signals are forced to their respective default reset values for the number of GPMC_FCLK cycles defined in CYCLE2CYCLEDELAY.

7.1.3.3.9.2 CSn: Chip-Select Signal Control Assertion/Deassertion Time (CSONTIME / CSRDOFFTIME / CSWROFFTIME / CSEXTRADELAY)

The GPMC_CONFIG2_i[3-0] CSONTIME field defines the CSn signal-assertion time relative to the start access time. It is common for read and write accesses.

Copyright © 2011, Texas Instruments Incorporated

The GPMC_CONFIG2_i[12-8] CSRDOFFTIME (read access) and GPMC_CONFIG2_i[20-16] CSWROFFTIME (write access) bit fields define the CSn signal deassertion time relative to start access time.

CSONTIME, CSRDOFFTIME and CSWROFFTIME parameters are applicable to synchronous and asynchronous modes. CSONTIME can be used to control an address and byte enable setup time before chip-select assertion. CSRDOFFTIME and CSWROFFTIME can be used to control an address and byte enable hold time after chip-select deassertion.

CSn signal transitions as controlled through CSONTIME, CSRDOFFTIME, and CSWROFFTIME can be delayed by half a GPMC_FCLK period by enabling the GPMC_CONFIG2_i[7] CSEXTRADELAY bit. This half of a GPMC_FCLK period provides more granularity on the CSn assertion and deassertion time to guarantee proper setup and hold time relative to GPMC_CLK. CSEXTRADELAY is especially useful in configurations where GPMC_CLK and GPMC_FCLK have the same frequency, but can be used for all GPMC configurations. If enabled, CSEXTRADELAY applies to all parameters controlling CSn transitions.

The CSEXTRADELAY bit must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the RDCYCLETIME and WRCYCLETIME bit fields to be greater than the CSn signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

7.1.3.3.9.3 ADVn/ALE: Address Valid/Address Latch Enable Signal Control Assertion/Deassertion Time (ADVONTIME / ADVRDOFFTIME / ADVWROFFTIME / ADVEXTRADELAY/ADVAADMUXONTIME/ADVAADMUXRDOFFTIME/ADVAADMUXWROFFTIME)

The GPMC_CONFIG3_i[3-0] ADVONTIME field defines the ADVn_ALE signal-assertion time relative to start access time. It is common to read and write accesses.

The GPMC_CONFIG3_i[12-8] ADVRDOFFTIME (read access) and GPMC_CONFIG3_i[20-16] ADVWROFFTIME (write access) bit fields define the ADVn_ALE signal-deassertion time relative to start access time.

ADVONTIME can be used to control an address and byte enable valid setup time control before ADVn_ALE assertion. ADVRDOFFTIME and ADVWROFFTIME can be used to control an address and byte enable valid hold time control after ADVn_ALE de-assertion. ADVRDOFFTIME and ADVWROFFTIME are applicable to both synchronous and asynchronous modes.

ADVn_ALE signal transitions as controlled through ADVONTIME, ADVRDOFFTIME, and ADVWROFFTIME can be delayed by half a GPMC_FCLK period by enabling the GPMC_CONFIG3_i[7] ADVEXTRADELAY bit. This half of a GPMC_FCLK period provides more granularity on ADVn_ALE assertion and deassertion time to assure proper setup and hold time relative to GPMC_CLK. The ADVEXTRADELAY configuration parameter is especially useful in configurations where GPMC_CLK and GPMC_FCLK have the same frequency, but can be used for all GPMC configurations. If enabled, ADVEXTRADELAY applies to all parameters controlling ADVn_ALE transitions.

ADVEXTRADELAY must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the RDCYCLETIME and WRCYCLETIME bit fields to be greater than ADVn_ALE signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

The GPMC_CONFIG3_i[6-4] ADVAADMUXONTIME, GPMC_CONFIG3_i[26-24] ADVAADMUXRDOFFTIME, and GPMC_CONFIG3_i[30-28] ADVAADMUXWROFFTIME parameters have the same functions as ADVONTIME, ADVRDOFFTIME, and ADVWROFFTIME, but apply to the first address phase in the AAD-multiplexed protocol. It is the user responsibility to make sure ADVAADMUXxxOFFTIME is programmed to a value lower than or equal to ADVxxOFFTIME. Functionality in AAD-mux mode is undefined if the settings do not comply with this requirement. ADVAADMUXxxOFFTIME can be programmed to the same value as ADVONTIME if no high ADVn pulse is needed between the two AAD-mux address phases, which is the typical case in synchronous mode. In this configuration, ADVn is kept low until it reaches the correct ADVxxOFFTIME.

See Section 7.1.3.3.12 for more details on ADVONTIME, ADVRDOFFTIME, ADVWROFFTIME, and ADVAADMUXRDOFFTIME, ADVAADMUXWROFFTIME usage for CLE and ALE (Command / Address Latch Enable) usage for a NAND Flash interface.

Copyright © 2011, Texas Instruments Incorporated

7.1.3.3.9.4 OEn/REn: Output Enable / Read Enable Signal Control Assertion / Deassertion Time (OEONTIME / OEOFFTIME / OEEXTRADELAY / OEAADMUXONTIME / OEAADMUXOFFTIME)

The GPMC_CONFIG4_i[3-0] OEONTIME field defines the OEn_REn signal assertion time relative to start access time. It is applicable only to read accesses.

The GPMC_CONFIG4_i[12-8] OEOFFTIME field defines the OEn_REn signal deassertion time relative to start access time. It is applicable only to read accesses. OEn_REn is not asserted during a write cycle.

OEONTIME, OEOFFTIME, OEAADMUXONTIME and OEAADMUXOFFTIME parameters are applicable to synchronous and asynchronous modes. OEONTIME can be used to control an address and byte enable valid setup time control before OEn_REn assertion. OEOFFTIME can be used to control an address and byte enable valid hold time control after OEn_REn assertion.

OEAADMUXONTIME and OEAADMUXOFFTIME parameters have the same functions as OEONTIME and OEOFFTIME, but apply to the first OE assertion in the AAD-multiplexed protocol for a read phase, or to the only OE assertion for a write phase. It is the user responsibility to make sure OEAADMUXOFFTIME is programmed to a value lower than OEONTIME. Functionality in AAD-mux mode is undefined if the settings do not comply with this requirement. OEAADMUXOFFTIME shall never be equal to OEONTIME because the AAD-mux protocol requires a second address phase with the OEn signal de-asserted before OEn can be asserted again to define a read command.

The OEn_REn signal transitions as controlled through OEONTIME, OEOFFTIME, OEAADMUXONTIME and OEAADMUXOFFTIME can be delayed by half a GPMC_FCLK period by enabling the GPMC_CONFIG4_i[7] OEEXTRADELAY bit. This half of a GPMC_FCLK period provides more granularity on OEn_REn assertion and deassertion time to assure proper setup and hold time relative to GPMC_CLK. If enabled, OEEXTRADELAY applies to all parameters controlling OEn_REn transitions.

OEEXTRADELAY must be used carefully, to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program RDCYCLETIME and WRCYCLETIME to be greater than OEn_REn signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

When the GPMC generates a read access to an address-/data-multiplexed device, it drives the address bus until OEn assertion time.

7.1.3.3.9.5 WEn: Write Enable Signal Control Assertion / Deassertion Time (WEONTIME / WEOFFTIME / WEEXTRADELAY)

The GPMC_CONFIG4_i[19-16] WEONTIME field (where i = 0 to 3) defines the WEn signal-assertion time relative to start access time. The GPMC_CONFIG4_i[28-24] WEOFFTIME field defines the WEn signal-deassertion time relative to start access time. These bit fields only apply to write accesses. WEn is not asserted during a read cycle.

WEONTIME can be used to control an address and byte enable valid setup time control before WEn assertion. WEOFFTIME can be used to control an address and byte enable valid hold time control after WEn assertion.

WEn signal transitions as controlled through WEONTIME, and WEOFFTIME can be delayed by half a GPMC_FCLK period by enabling the GPMC_CONFIG4_i[23] WEEXTRADELAY bit. This half of a GPMC_FCLK period provides more granularity on WEn assertion and deassertion time to guaranty proper setup and hold time relative to GPMC_CLK. If enabled, WEEXTRADELAY applies to all parameters controlling WEn transitions.

The WEEXTRADELAY bit must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the WRCYCLETIME bit field to be greater than the WEn signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

Copyright © 2011, Texas Instruments Incorporated

7.1.3.3.9.6 GPMC_CLK

GPMC_CLK is the external clock provided to the attached synchronous memory or device.

- The GPMC_CLK clock frequency is the GPMC_FCLK functional clock frequency divided by 1, 2, 3, or 4, depending on the GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER bit field, with a guaranteed 50-percent duty cycle.
- The GPMC_CLK clock is only activated when the access in progress is defined as synchronous (read or write access).
- The GPMC_CONFIG1_i[26-25] CLKACTIVATIONTIME field defines the number of GPMC_FCLK cycles from start access time to GPMC_CLK activation.
- The GPMC_CLK clock is stopped when cycle time completes and is asserted low between accesses.
- The GPMC_CLK clock is kept low when access is defined as asynchronous.
- When the GPMC is configured for synchronous mode, the GPMC_CLK signal (which is an output) must also be set as an input in the Pin Mux configuration for the pin. GPMC_CLK is looped back through the output and input buffers of the corresponding GPMC_CLK pad at the device boundary. The looped-back clock is used to synchronize the sampling of the memory signals.

When cycle time completes, the GPMC_CLK may be high because of the GPMCFCLKDIVIDER bit field. To ensure correct stoppage of the GPMC_CLK clock within the 50-percent required duty cycle, it is the user's responsibility to extend the RDCYCLETIME or WRCYCLETIME value.

To ensure a correct external clock cycle, the following rules must be applied:

- (RDCYCLETIME - CLKACTIVATIONTIME) must be a multiple of (GPMCFCLKDIVIDER + 1).
- The PAGEBURSTACCESSTIME value must be a multiple of (GPMCFCLKDIVIDER + 1).

7.1.3.3.9.7 GPMC_CLK and Control Signals Setup and Hold

Control-signal transition (assertion and deassertion) setup and hold values with respect to the GPMC_CLK edge can be controlled in the following ways:

- For the GPMC_CLK signal, the GPMC_CONFIG1_i[26-25] CLKACTIVATIONTIME field allows setup and hold control of control-signal assertion time.
- The use of a divided GPMC_CLK allows setup and hold control of control-signal assertion and deassertion times.
- When GPMC_CLK runs at the GPMC_FCLK frequency so that GPMC_CLK edge and control-signal transitions refer to the same GPMC_FCLK edge, the control-signal transitions can be delayed by half of a GPMC_FCLK period to provide minimum setup and hold times. This half-GPMC_FCLK delay is enabled with the CSEXTRADELAY, ADVEXTRADELAY, OEEXTRADELAY, or WEEXTRADELAY parameter. This delay must be used carefully to prevent control-signal overlap between successive accesses to different chip-selects. This implies that the RDCYCLETIME and WRCYCLETIME are greater than the last control-signal deassertion time, including the extra half-GPMC_FCLK cycle.

7.1.3.3.9.8 Access Time (RDACCESSTIME / WRACCESSTIME)

The read access time and write access time durations can be programmed independently through GPMC_CONFIG5_i[20-16] RDACCESSTIME and GPMC_CONFIG6_i[28-24] WRACCESSTIME. This allows OEn and GPMC data capture timing parameters to be independent of WEn and memory device data capture timing parameters. RDACCESSTIME and WRACCESSTIME bit fields can be set with a granularity of 1 or 2 throught GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY.

7.1.3.3.9.8.1 Access Time on Read Access

In asynchronous read mode, for single and paged accesses, GPMC_CONFIG5_i[[20-16] RDACCESSTIME field defines the number of GPMC_FCLK cycles from start access time to the GPMC_FCLK rising edge used for the first data capture. RDACCESSTIME must be programmed to the rounded greater value (in GPMC_FCLK cycles) of the read access time of the attached memory device.

In synchronous read mode, for single or burst accesses, RDACCESSTIME defines the number of GPMC_FCLK cycles from start access time to the GPMC_FCLK rising edge corresponding to the GPMC_CLK rising edge used for the first data capture.

Copyright © 2011, Texas Instruments Incorporated

GPMC_CLK which is sent to the memory device for synchronization with the GPMC controller, is internally retimed to correctly latch the returned data. GPMC_CONFIG5_i[4-0] RDCYCLETIME must be greater than RDACCESSTIME in order to let the GPMC latch the last return data using the internally retimed GPMC_CLK.

The external WAIT signal can be used in conjunction with RDACCESSTIME to control the effective GPMC data-capture GPMC_FCLK edge on read access in both asynchronous mode and synchronous mode. For details about wait monitoring, see Section 7.1.3.3.8.1.

7.1.3.3.9.8.2 Access Time on Write Access

In asynchronous write mode, the GPMC_CONFIG6_i[[28-24] WRACCESSTIME timing parameter is not used to define the effective write access time. Instead, it is used as a WAIT invalid timing window, and must be set to a correct value so that the gpmc_wait pin is at a valid state two GPMC_CLK cycles before WRACCESSTIME completes. For details about wait monitoring, see Section 7.1.3.3.8.1.

In synchronous write mode , for single or burst accesses, WRACCESSTIME defines the number of GPMC_FCLK cycles from start access time to the GPMC_CLK rising edge used by the memory device for the first data capture.

The external WAIT signal can be used in conjunction with WRACCESSTIME to control the effective memory device data capture GPMC_CLK edge for a synchronous write access. For details about wait monitoring, see Section 7.1.3.3.8.1.

7.1.3.3.9.9 Page Burst Access Time (PAGEBURSTACCESSTIME)

GPMC_CONFIG5_i[27-24] PAGEBURSTACCESSTIME bit field can be set with a granularity of 1 or 2 throught the GPMC_CONFIG1_i[[4] TIMEPARAGRANULARITY.

7.1.3.3.9.9.1 Page Burst Access Time on Read Access

In asynchronous page read mode, the delay between successive word captures in a page is controlled through the PAGEBURSTACCESSTIME bit field. The PAGEBURSTACCESSTIME parameter must be programmed to the rounded greater value (in GPMC_FCLK cycles) of the read access time of the attached device.

In synchronous burst read mode, the delay between successive word captures in a burst is controlled through the PAGEBURSTACCESSTIME field.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective GPMC data capture GPMC_FCLK edge on read access. For details about wait monitoring, see Section 7.1.3.3.8.1.

7.1.3.3.9.9.2 Page Burst Access Time on Write Access

Asynchronous page write mode is not supported. PAGEBURSTACCESSTIME is irrelevant in this case.

In synchronous burst write mode, PAGEBURSTACCESSTIME controls the delay between successive memory device word captures in a burst.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective memory-device data capture GPMC_CLK edge in synchronous write mode. For details about wait monitoring, see Section 7.1.3.3.8.1.

7.1.3.3.9.10 Bus Keeping Support

At the end-cycle time of a read access, if no other access is pending, the GPMC drives the bus with the last data read after RDCYCLETIME completion time to prevent bus floating and reduce power consumption.

After a write access, if no other access is pending, the GPMC keeps driving the data bus after WRCYCLETIME completes with the same data to prevent bus floating and power consumption.

Copyright © 2011, Texas Instruments Incorporated

7.1.3.3.10 NOR Access Description

For each chip-select configuration, the read access can be specified as either asynchronous or synchronous access through the GPMC_CONFIG1_i[29] READTYPE bit. For each chip-select configuration, the write access can be specified as either synchronous or asynchronous access through the GPMC_CONFIG1_i[27] WRITETYPE bit.

Asynchronous and synchronous read and write access time and related control signals are controlled through timing parameters that refer to GPMC_FCLK. The primary difference of synchronous mode is the availability of a configurable clock interface (GPMC_CLK) to control the external device. Synchronous mode also affects data-capture and wait-pin monitoring schemes in read access.

For details about asynchronous and synchronous access, see the descriptions of GPMC_CLK, RdAccessTime, WrAccessTime, and wait-pin monitoring.

For more information about timing-parameter settings, see the sample timing diagrams in this chapter.

The address bus and BE[1:0]n are fixed for the duration of a synchronous burst read access, but they are updated for each beat of an asynchronous page-read access.

7.1.3.3.10.1 Asynchronous Access Description

This section describes:

- Asynchronous single read operation on an address/data multiplexed device
- Asynchronous single write operation on an address/data-multiplexed device
- Asynchronous single read operation on an AAD-multiplexed device
- Asynchronous single write operation on an AAD-multiplexed device
- Asynchronous multiple (page) read operation on a non-multiplexed device

In asynchronous operations GPMC_CLK is not provided outside the GPMC and is kept low.

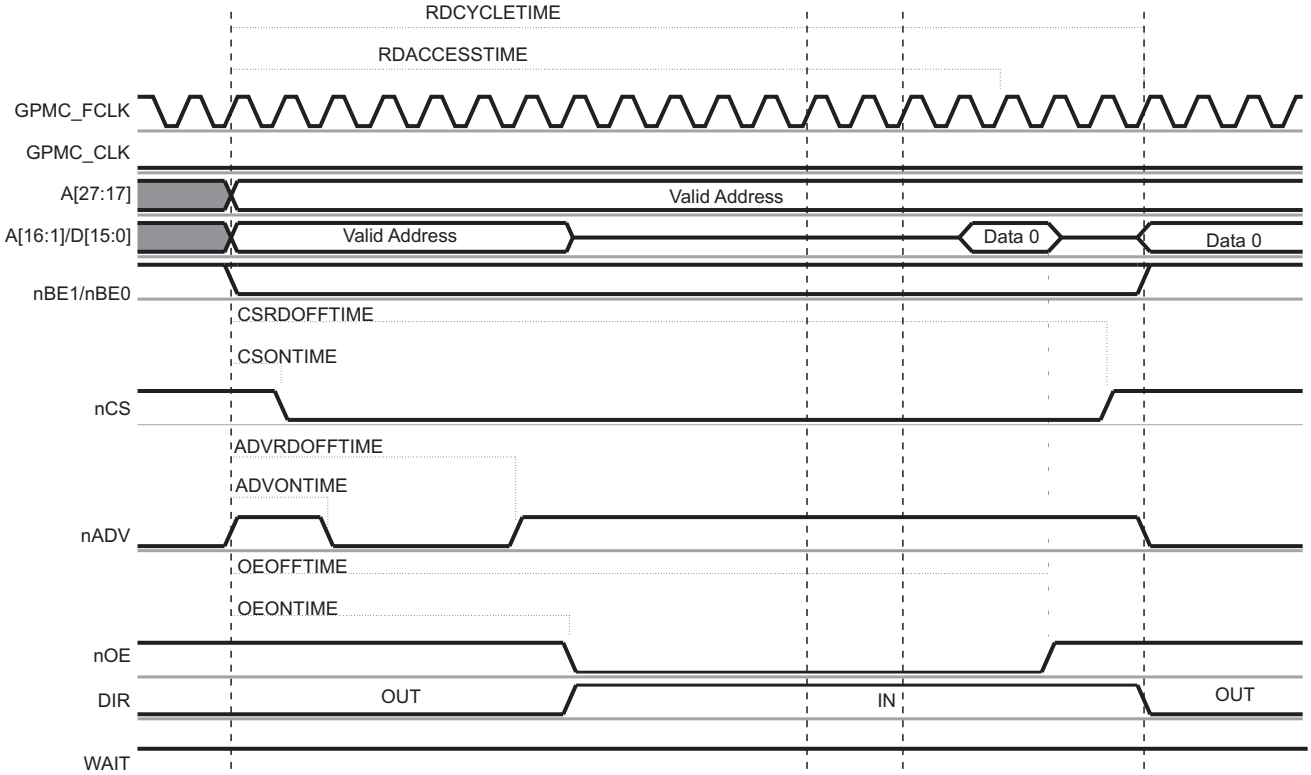
7.1.3.3.10.1.1 Access on Address/Data Multiplexed Devices

7.1.3.3.10.1.1.1 Asynchronous Single-Read Operation on an Address/Data Multiplexed Device

Figure 7-12 shows an asynchronous single read operation on an address/data-multiplexed device.

Figure 7-12. Asynchronous Single Read Operation on an Address/Data Multiplexed Device



7.1.3.3.10.1.1.2 Asynchronous Single Read on an Address/Data-Multiplexed Device

See Section 7.1.3.9.1 for formulas to calculate timing parameters.

Table 7-41 lists the timing bit fields to set up in order to configure the GPMC in asynchronous single read mode.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until OEn assertion time. For details, see Section 7.1.3.3.8.2.3.

Address bits (A[16:1] from a GPMC perspective, A[15:0] from an external device perspective) are placed on the address/data bus, and the remaining address bits GPMC_A[25:16] are placed on the address bus. The address phase ends at OEn assertion, when the DIR signal goes from OUT to IN.

- Chip-select signal CSn
  - CSn assertion time is controlled by the GPMC_CONFIG2_i[3-0] CSONTIME field. It controls the address setup time to CSn assertion.
  - CSn deassertion time is controlled by the GPMC_CONFIG2_i[12-8] CSRDOFFTIME field. It controls the address hold time from CSn deassertion
- Address valid signal ADVn
  - ADVn assertion time is controlled by the GPMC_CONFIG3_i[3-0] ADVONTIME field.
  - ADVn deassertion time is controlled by the GPMC_CONFIG3_i[[12-8] ADVRDOFFTIME field.

Copyright © 2011, Texas Instruments Incorporated

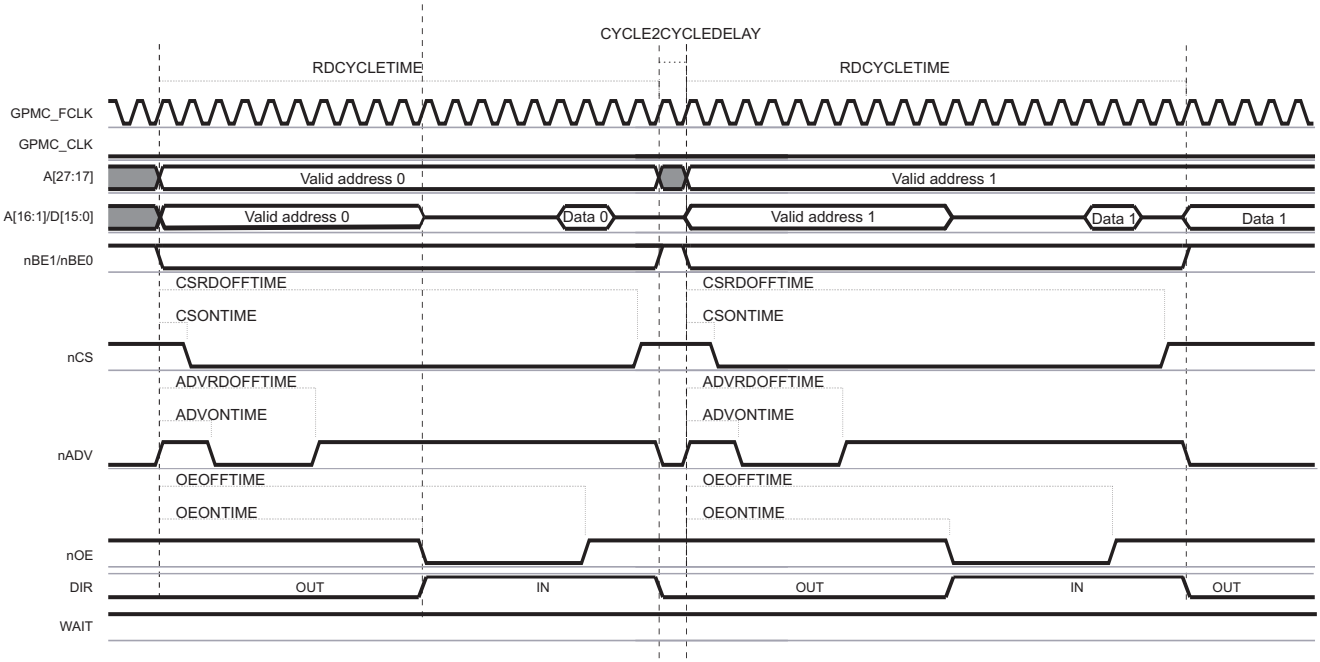
- Output enable signal OEn
  - OEn assertion indicates a read cycle.
  - OEn assertion time is controlled by the GPMC_CONFIG4_i[[3-0] OEONTIME field.
  - OEn deassertion time is controlled by the GPMC_CONFIG4_i[[12-8] OEOFFTIME field.
- Read data is latched when RDACCESSTIME completes. Access time is defined in the GPMC_CONFIG5_i[20-16] RDACCESSTIME field.
- Direction signal DIR: DIR goes from OUT to IN at the same time that OEn is asserted.
- The end of the access is defined by the GPMC_CONFIG5_i[4-0] RDCYCLETIME parameter.

In the GPMC, when a 16-bit wide device is attached to the controller, a 32-bit word write access is split into two 16-bit word write accesses. For more information about GPMC access size and type adaptation, see Section 7.1.3.3.10.5. Between two successive accesses, if a OEn pulse is needed:

- The GPMC_CONFIG6_i[[11-8] CYCLE2CYCLEDELAY field can be programmed with GPMC_CONFIG6_i[[7] CYCLE2CYCLESAMECSEN enabled.
- The CSWROFFTIME and CSONTIME parameters also allow a chip-select pulse, but this affects all other types of access.

Figure 7-13 shows two asynchronous single-read accesses on an address/data-multiplexed devices.

Figure 7-13. Two Asynchronous Single Read Accesses on an Address/Data Multiplexed Device (32-Bit Read Split Into 2 × 16-Bit Read)

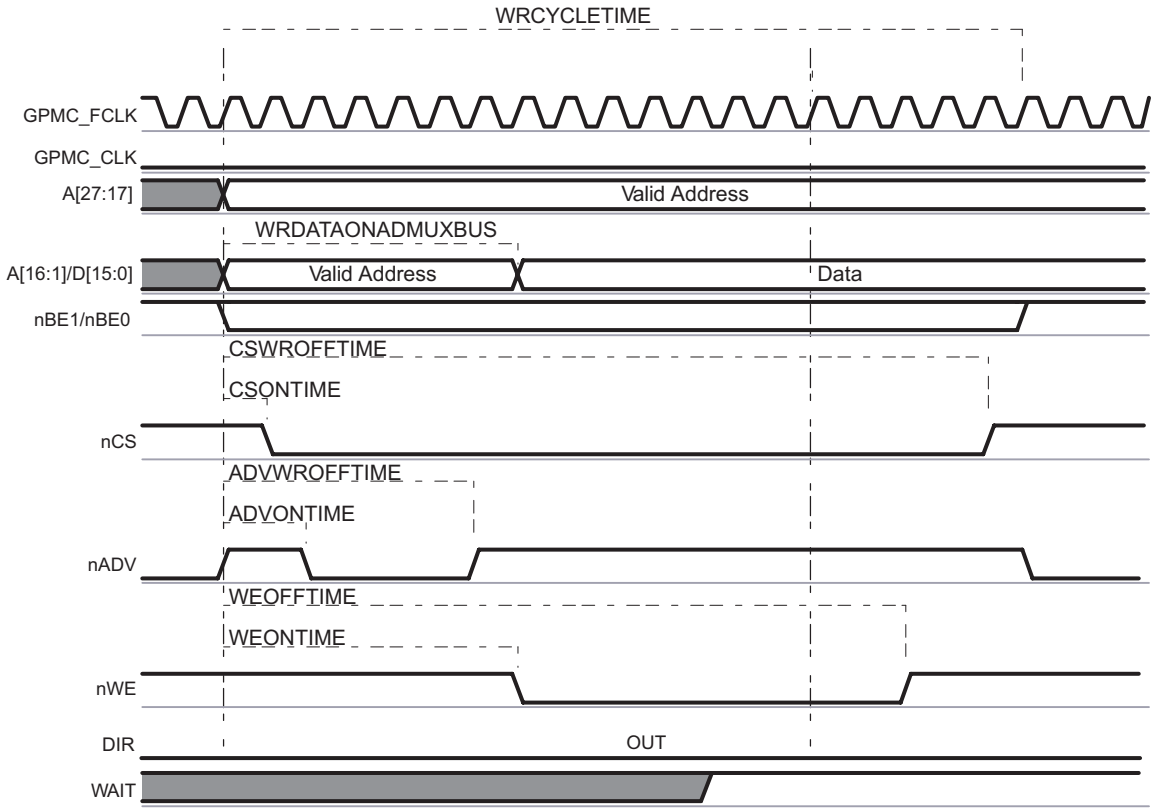


Copyright © 2011, Texas Instruments Incorporated

7.1.3.3.10.1.1.3 Asynchronous Single Write Operation on an Address/Data-Multiplexed Device

Figure 7-14 shows an asynchronous single write operation on an address/data-multiplexed device.

Figure 7-14. Asynchronous Single Write on an Address/Data-Multiplexed Device



7.1.3.3.10.1.1.4 Asynchronous Single Write on an Address/Data-Multiplexed Device

See Section 7.1.3.9.1 for formulas to calculate timing parameters.

Table 7-41 lists the timing bit fields to set up in order to configure the GPMC in asynchronous single write mode. When the GPMC generates a write access to an address/data-multiplexed device, it drives the address bus until WEn assertion time. For more information, see Section 7.1.3.3.8.2.3.

The CSn and ADVn signals are controlled in the same way as for asynchronous single read operation on an address/data-multiplexed device.

- Write enable signal WEn
  - WEn assertion indicates a write cycle.
  - WEn assertion time is controlled by the GPMC_CONFIG4_i[19-16] WEONTIME field.
  - WEn deassertion time is controlled by the GPMC_CONFIG4_i[28-24] WEOFFTIME field.
- Direction signal DIR: DIR signal is OUT during the entire access.
- The end of the access is defined by the GPMC_CONFIG5_i[12-8] WRCYCLETIME parameter.

Address bits A[16:1] (GPMC point of view) are placed on the address/data bus at the start of cycle time, and the remaining address bits A[26:17] are placed on the address bus.

Data is driven on the address/data bus at a GPMC_CONFIG6_i[19-16] WRDATAONADMUXBUS time.

Write multiple access in asynchronous mode is not supported. If WRITEMULTIPLE is enabled with WRITETYPE as asynchronous, the GPMC processes single asynchronous accesses.

Copyright © 2011, Texas Instruments Incorporated

After a write operation, if no other access (read or write) is pending, the data bus keeps its previous value. See Section 7.1.3.3.9.10.

7.1.3.3.10.1.1.5 Asynchronous Multiple (Page) Write Operation on an Address/Data-Multiplexed Device

Write multiple (page) access in asynchronous mode is not supported for address/data-multiplexed devices. If GPMC_CONFIG1_i[28] WRITEMULTIPLE is enabled (1) with GPMC_CONFIG1_i[27] WRITETYPE as asynchronous (0), the GPMC processes single asynchronous accesses.

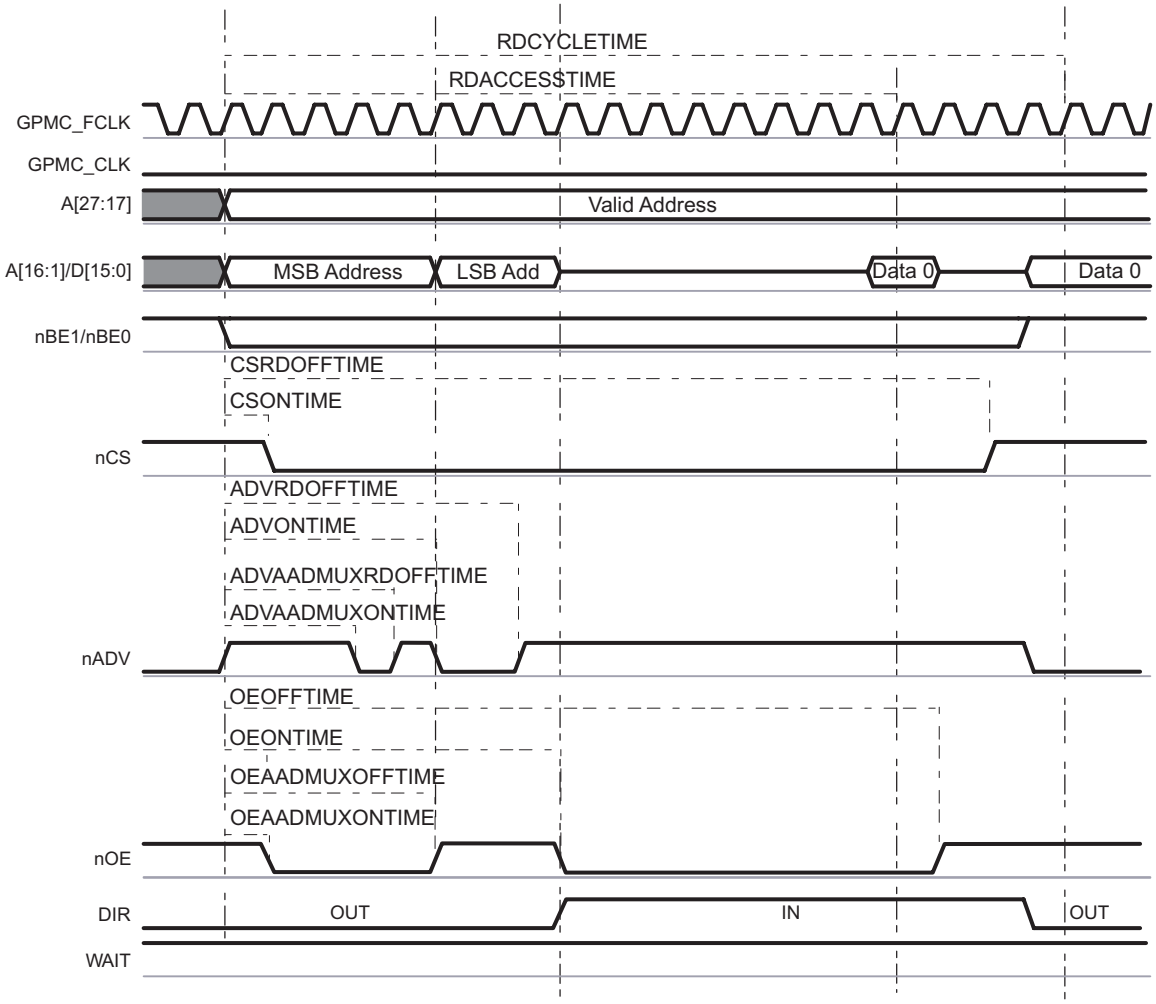
For accesses on non-multiplexed devices, see Section 7.1.3.3.10.3.

7.1.3.3.10.1.2 Access on Address/Address/Data (AAD) Multiplexed Devices

7.1.3.3.10.1.2.1 Asynchronous Single Read Operation on an AAD-Multiplexed Device

Figure 7-15 shows an asynchronous single read operation on an AAD-multiplexed device.

Figure 7-15. Asynchronous Single-Read on an AAD-Multiplexed Device



Copyright © 2011, Texas Instruments Incorporated

7.1.3.3.10.1.2.2 Asynchronous Single Read on an AAD-Multiplexed Device

See Section 7.1.3.9.1 for formulas to calculate timing parameters.

Table 7-41 lists the timing bit fields to set up in order to configure the GPMC in asynchronous single write mode.

When the GPMC generates a read access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with OEn driven low. The first address phase ends at the first OEn deassertion time. The second phase for LSB address is qualified with OEn driven high. The second address phase ends at the second OEn assertion time, when the DIR signal goes from OUT to IN.

The CSn and DIR signals are controlled in the same way as for asynchronous single read operation on an address/data-multiplexed device.

- Address valid signal ADVn. ADVn is asserted and deasserted twice during a read transaction:
  - ADVn first assertion time is controlled by the GPMC_CONFIG3_i[6-4] ADVAADMUXONTIME field.
  - ADVn first deassertion time is controlled by the GPMC_CONFIG3_i[26-24] ADVAADMUXRDOFFTIME field.
  - ADVn second assertion time is controlled by the GPMC_CONFIG3_i[3-0] ADVONTIME field.
  - ADVn second deassertion time is controlled by the GPMC_CONFIG3_i[12-8] ADVRDOFFTIME field.
- Output Enable signal OEn. OEn is asserted and deasserted twice during a read transaction (OEn second assertion indicates a read cycle):
  - OEn first assertion time is controlled by the GPMC_CONFIG4_i[6-4] OEAADMUXONTIME field.
  - OEn first deassertion time is controlled by the GPMC_CONFIG3_i[15-13] OEAADMUXOFFTIME field.
  - OEn second assertion time is controlled by the GPMC_CONFIG4_i[3-0] OEONTIME field.
  - OEn second deassertion time is controlled by the GPMC_CONFIG4_i[12-8] OEOFFTIME field.

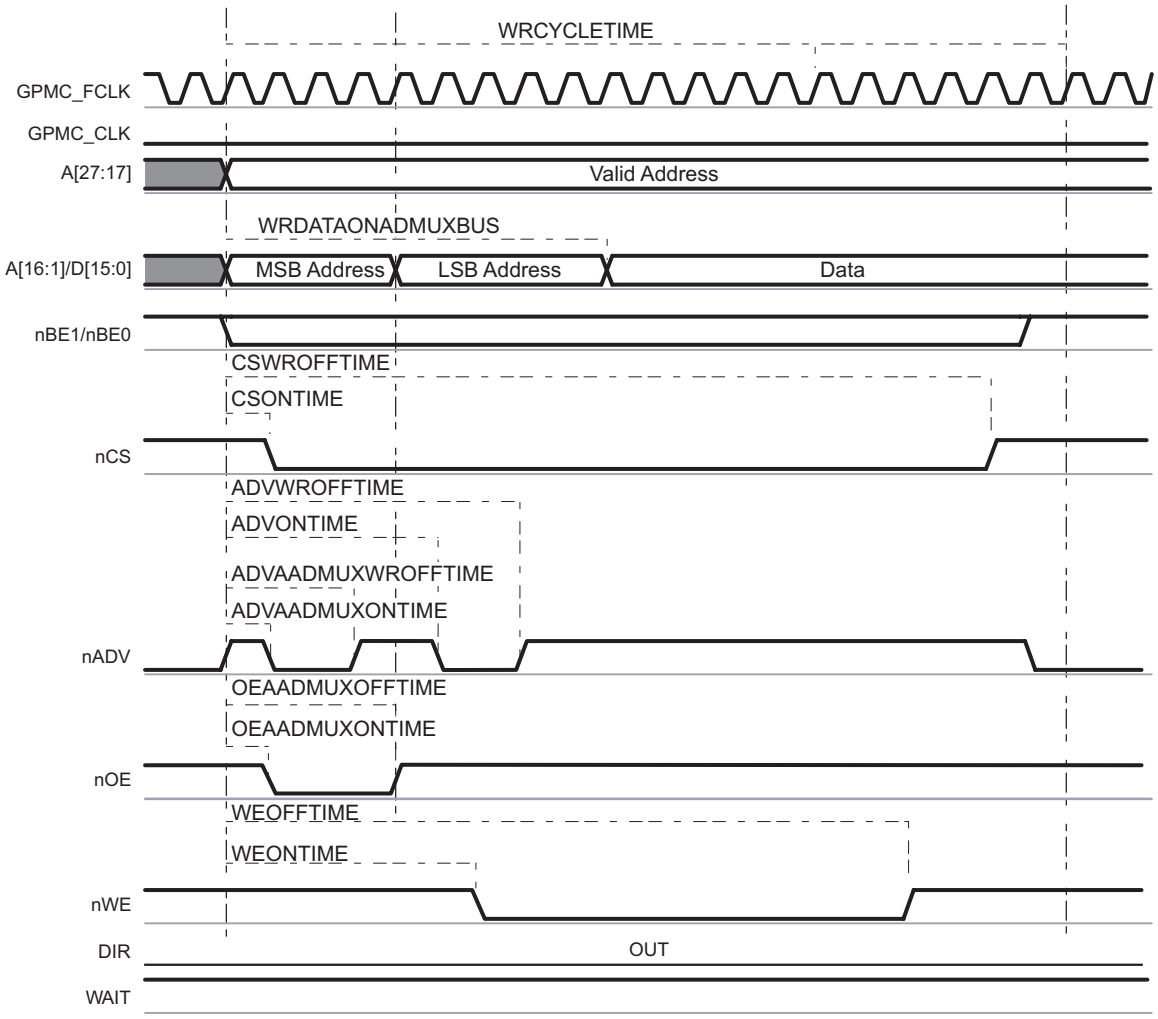
7.1.3.3.10.1.2.3 Asynchronous Single Write Operation on an AAD-Multiplexed Device

Figure 7-16 shows an asynchronous single write operation on an AAD-multiplexed device.

Figure 7-16. Asynchronous Single Write on an AAD-Multiplexed Device



Copyright © 2011, Texas Instruments Incorporated

See Section 7.1.3.9.1 for formulas to calculate timing parameters.

Table 7-41 lists the timing bit fields to set up to configure the GPMC in asynchronous single write mode.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with OEn driven low. The second phase for LSB address is qualified with OEn driven high. The address phase ends at WEn assertion time.

The CSn, WEn, and DIR signals are controlled in the same way as for asynchronous single write operation on an address/data-multiplexed device.

- Address valid signal ADVn is asserted and deasserted twice during a write transaction
  - ADVn first assertion time is controlled by the GPMC_CONFIG3_i[6-4] ADVAADMUXONTIME field.
  - ADVn first deassertion time is controlled by the GPMC_CONFIG3_i[30-28] ADVAADMUXWROFFTIME field.
  - ADVn second assertion time is controlled by the GPMC_CONFIG3_i[3-0] ADVONTIME field.
  - ADVn second deassertion time is controlled by the GPMC_CONFIG3_i[20-16] ADVWROFFTIME field.
- Output Enable signal OEn is asserted during the address phase of a write transaction
  - OEn assertion time is controlled by the GPMC_CONFIG4_i[6-4] OEAADMUXONTIME field.
  - OEn deassertion time is controlled by the GPMC_CONFIG3_i[15-13] OEAADMUXOFFTIME field.

The address bits for the first address phase are driven onto the data bus until OEn deassertion. Data is driven onto the address/data bus at the clock edge defined by the GPMC_CONFIG6_i[19-16] WRDATAONADMUXBUS parameter.

7.1.3.3.10.1.2.4 Asynchronous Multiple (Page) Read Operation on an AAD-Multiplexed Device

Write multiple (page) access in asynchronous mode is not supported for AAD-multiplexed devices.

If GPMC_CONFIG1_i[28] WRITEMULTIPLE is enabled (1) with GPMC_CONFIG1_i[27] WRITETYPE as asynchronous (0), the GPMC processes single asynchronous accesses.

For accesses on non-multiplexed devices, see Section 7.1.3.3.10.3.

7.1.3.3.10.2 Synchronous Access Description

This section details read and write synchronous accesses on address/data multiplexed. All information in this section can be applied to any type of memory - non-multiplexed, address and data multiplexed or AAD-multiplexed - with a difference limited to the address phase. For accesses on non-multiplexed devices, see Section 7.1.3.3.10.3.

In synchronous operations:

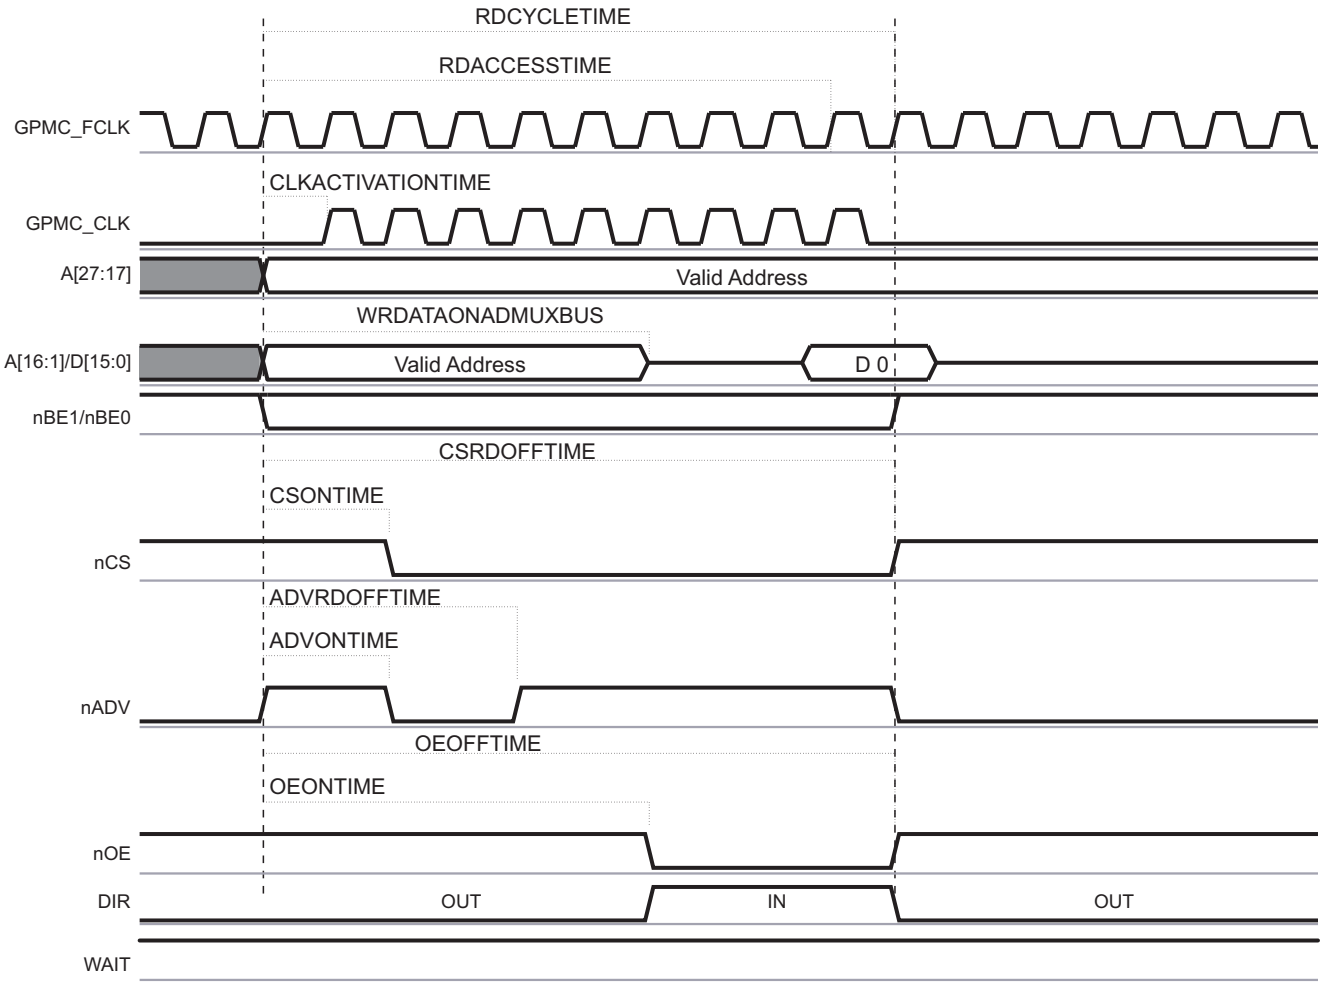
- The GPMC_CLK clock is provided outside the GPMC when accessing the memory device.
- The GPMC_CLK clock is derived from the GPMC_FCLK clock using the GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER field. In the following section, i stands for the chip-select number, i = 0 to 3.
- The GPMC_CONFIG1_i[26-25] CLKACTIVATIONTIME field specifies that the GPMC_CLK is provided outside the GPMC 0, 1, or 2 GPMC_FCLK cycles after start access time until RDCYCLETIME or WRCYCLETIME completion.

Copyright © 2011, Texas Instruments Incorporated

7.1.3.3.10.2.1 Synchronous Single Read

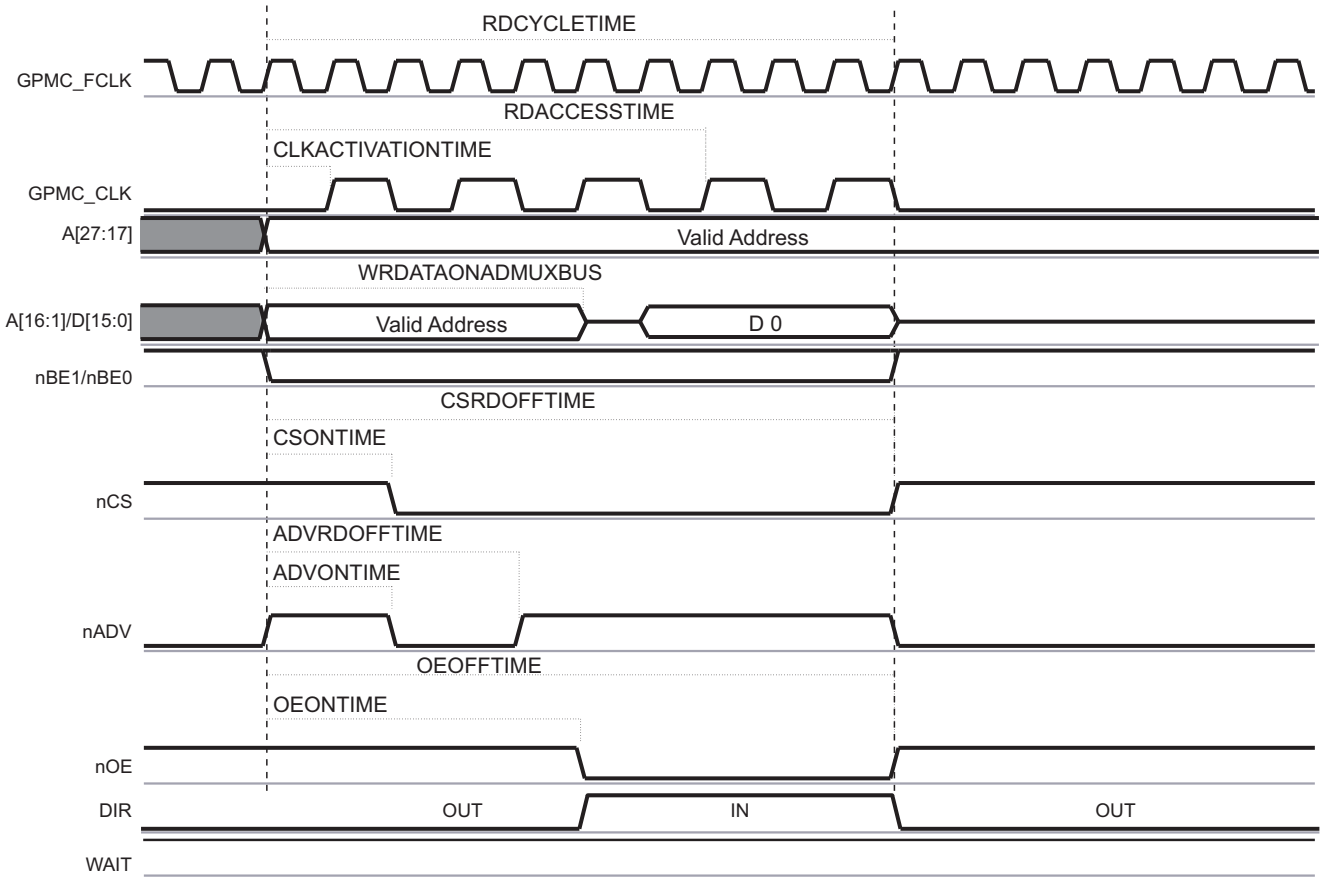
Figure 7-17 and Figure 7-18 show a synchronous single-read operation with GPMCFCLKDIVIDER equal to 0 and 1, respectively.

Figure 7-17. Synchronous Single Read (GPMCFCLKDIVIDER = 0)



Copyright © 2011, Texas Instruments Incorporated

Figure 7-18. Synchronous Single Read (GPMCFCLKDIVIDER = 1)



See Section 7.1.3.9.1 for formulas to calculate timing parameters.

Table 7-41 lists the timing bit fields to set up in order to configure the GPMC in asynchronous single read mode.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until OEn assertion time. For details, see Section 7.1.3.3.8.2.3.

- Chip-select signal CSn
  - CSn assertion time is controlled by the GPMC_CONFIG2_i[3-0] CSONTIME field and ensures address setup time to CSn assertion.
  - CSn deassertion time is controlled by the GPMC_CONFIG2_i[12-8] CSRDOFFTIME field and ensures address hold time to CSn deassertion.
- Address valid signal ADVn
  - ADVn assertion time is controlled by the GPMC_CONFIG3_i[3-0] ADVONTIME field.
  - ADVn deassertion time is controlled by the GPMC_CONFIG3_i[12-8] ADVRDOFFTIME field.
- Output enable signal OEn
  - OEn assertion indicates a read cycle.
  - OEn assertion time is controlled by the GPMC_CONFIG4_i[3-0] OEONTIME field.
  - OEn deassertion time is controlled by the GPMC_CONFIG4_i[12-8] OEOFFTIME field.
- Initial latency for the first read data is controlled by GPMC_CONFIG5_i[20-16] RDACCESSTIME or by monitoring the WAIT signal.
- Total access time (GPMC_CONFIG5_i[4-0] RDCYCLETIME) corresponds to RDACCESSTIME plus the address hold time from CSn deassertion, plus time from RDACCESSTIME to CSRDOFFTIME.

Copyright © 2011, Texas Instruments Incorporated

- Direction signal DIR: DIR goes from OUT to IN at the same time as OEn assertion.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with OEn driven low. The second phase for LSB address is qualified with OEn driven high. The address phase ends at WEn assertion time.

The CSn and DIR signals are controlled in the same way as for synchronous single read operation on an address/data-multiplexed device.

- Address valid signal ADVn is asserted and deasserted twice during a read transaction
  - ADVn first assertion time is controlled by the GPMC_CONFIG3_i[6-4] ADVAADMUXONTIME field.
  - ADVn first deassertion time is controlled by the GPMC_CONFIG3_i[26-24] ADVAADMUXRDOFFTIME field.
  - ADVn second assertion time is controlled by the GPMC_CONFIG3_i[3-0] ADVONTIME field.
  - ADVn second deassertion time is controlled by the GPMC_CONFIG3_i[12-8] ADVRDOFFTIME field.
- Output Enable signal OEn is asserted and deasserted twice during a read transaction (OEn second assertion indicates a read cycle)
  - OEn first assertion time is controlled by the GPMC_CONFIG4_i[6-4] OEAADMUXONTIME field.
  - OEn first deassertion time is controlled by the GPMC_CONFIG3_i[15-13] OEAADMUXOFFTIME field.
  - OEn second assertion time is controlled by the GPMC_CONFIG4_i[3-0] OEONTIME field.
  - OEn second deassertion time is controlled by the GPMC_CONFIG4_i[12-8] OEOFFTIME field.

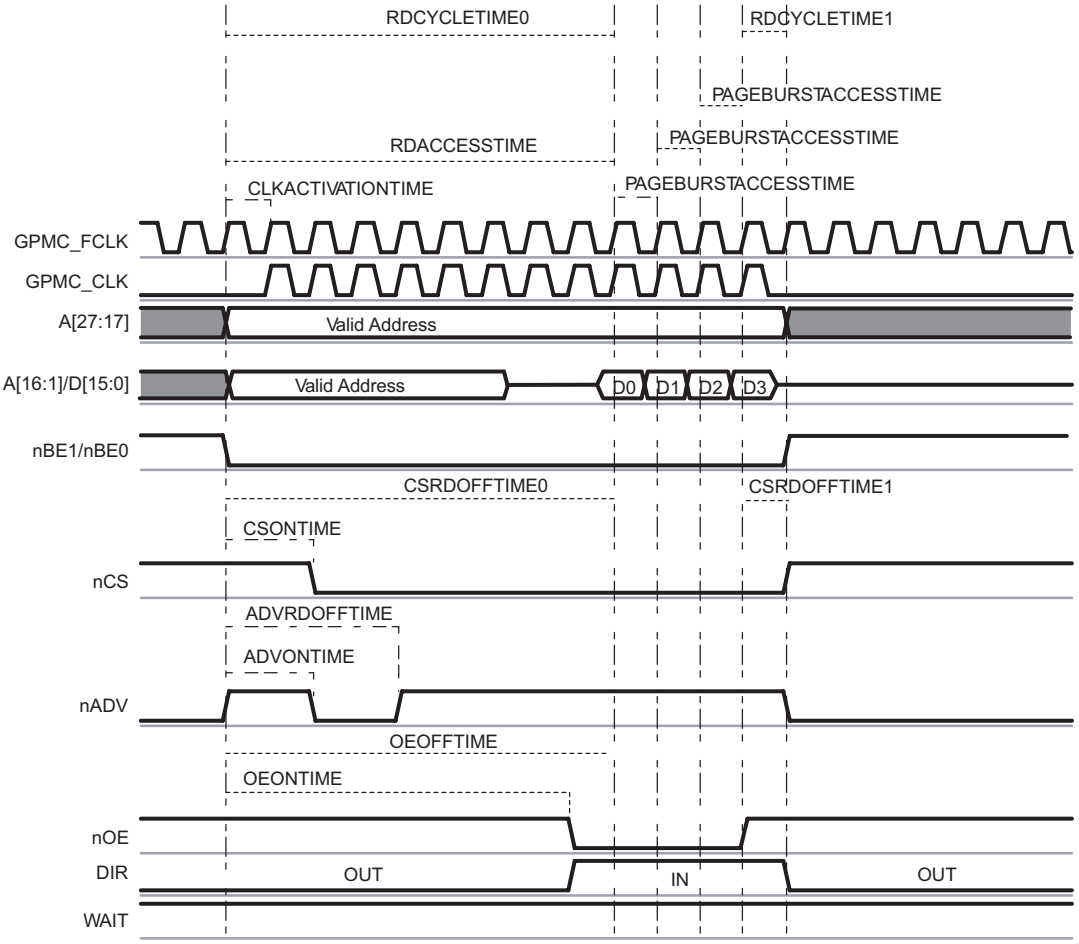
After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See Section 7.1.3.3.9.10.

Copyright © 2011, Texas Instruments Incorporated

7.1.3.3.10.2.2 Synchronous Multiple (Burst) Read (4-, 8-, 16-Word16 Burst With Wraparound Capability)

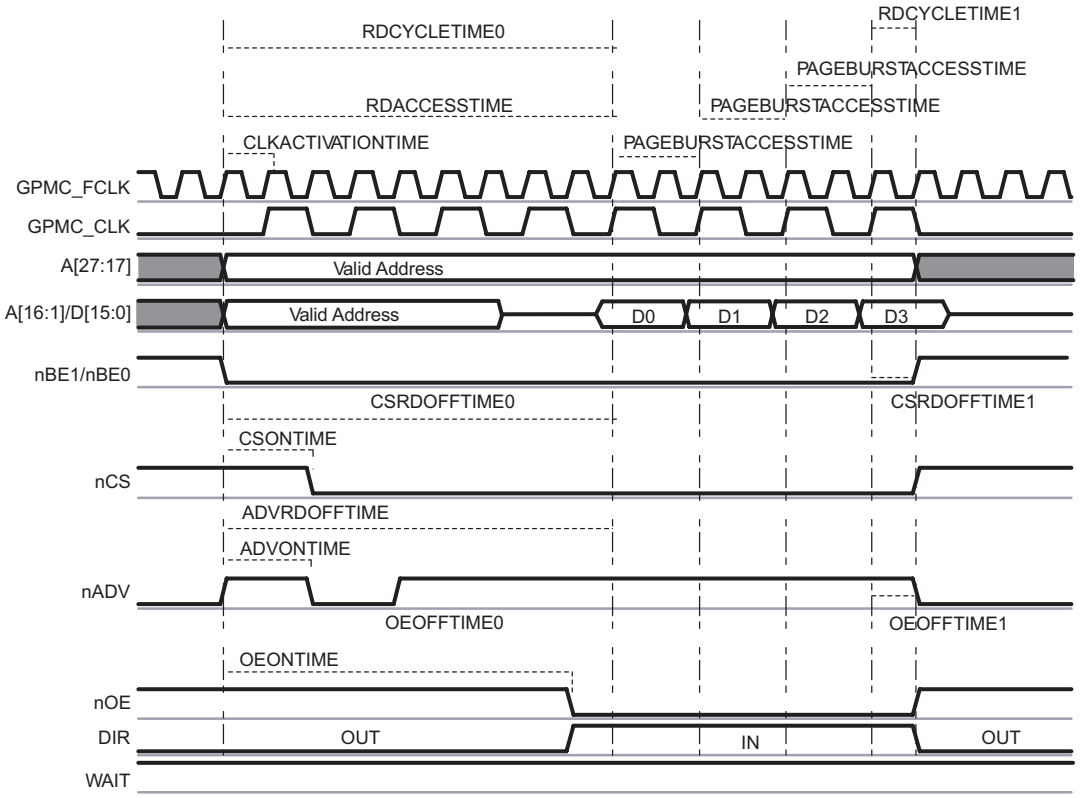
Figure 7-19 and Figure 7-20 show a synchronous multiple read operation with GPMCFCLKDivider equal to 0 and 1, respectively.

Figure 7-19. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 0)



Copyright © 2011, Texas Instruments Incorporated

Figure 7-20. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 1)



When GPMC_CONFIG5_i[20-16] RDACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to GPMC_CONFIG5_i[27-24] PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

The CSn, ADVn, OEn and DIR signals are controlled in the same way as for synchronous single read operation. See Section 7.1.3.3.10.2.1.

Initial latency for the first read data is controlled by RDACCESSTIME or by monitoring the WAIT signal. Successive read data are provided by the memory device each one or two GPMC_CLK cycles. The PAGEBURSTACCESSTIME parameter must be set accordingly with GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER and the memory-device internal configuration. Depending on the device page length, the GPMC checks device page crossing during a new burst request and purposely insert initial latency (of RDACCESSTIME) when required.

Total access time GPMC_CONFIG5_i[4-0] RDCYCLETIME corresponds to RDACCESSTIME plus the address hold time from CSn deassertion. In Figure 7-19, RDCYCLETIME programmed value equals to RDCYCLETIME0 + RDCYCLETIME1.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See Section 7.1.3.3.9.10.

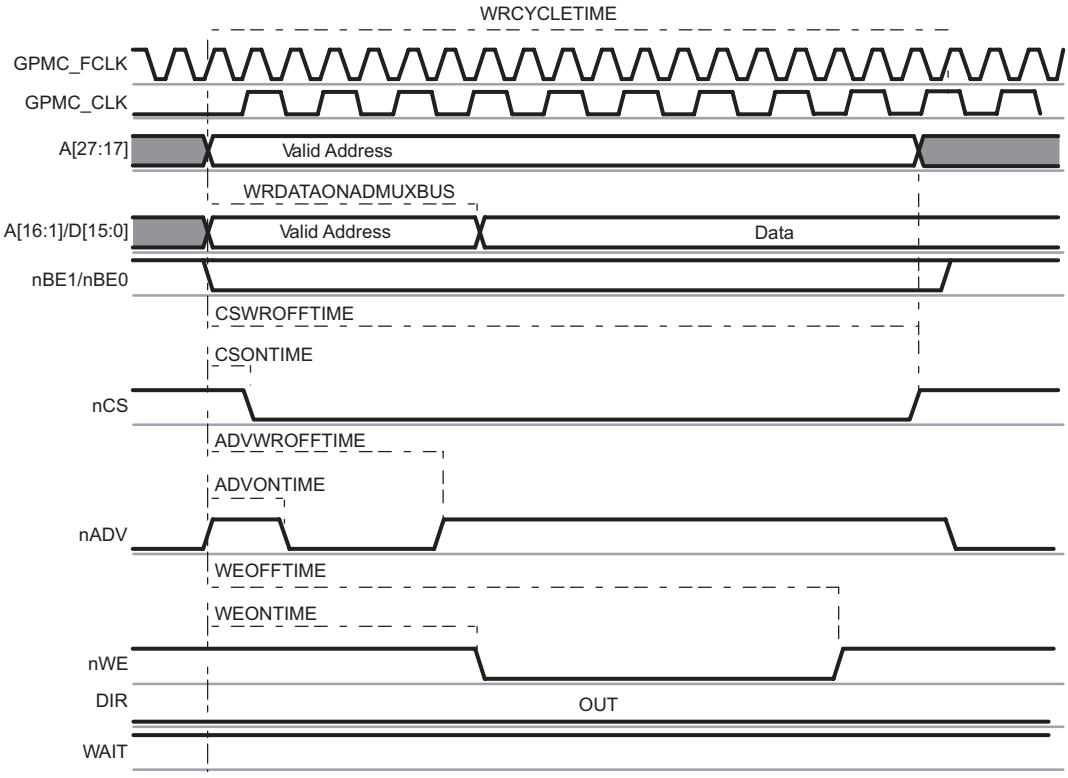
Burst wraparound is enabled through the GPMC_CONFIG1_i[31] WRAPBURST bit and allows a 4-, 8-, or 16-Word16 linear burst access to wrap within its burst-length boundary through GPMC_CONFIG1_i[24-23] ATTACHEDDEVICEPAGELENGTH.

Copyright © 2011, Texas Instruments Incorporated

7.1.3.3.10.2.3 Synchronous Single Write

Burst write mode is used for synchronous single or burst accesses (see Figure 7-21).

Figure 7-21. Synchronous Single Write on an Address/Data-Multiplexed Device



When the GPMC generates a write access to an address/data-multiplexed device, it drives the data bus (with address bits A[16:1]) until [19:16] WRDATAONADMUXBUS time. First data of the burst is driven on the address/data bus at WRDATAONADMUXBUS time.

Copyright © 2011, Texas Instruments Incorporated

7.1.3.3.10.2.4 Synchronous Multiple (Burst) Write

Synchronous burst write mode provides synchronous single or consecutive accesses. Figure 7-22 shows a synchronous burst write access when the chip-select is configured in address/data-multiplexed mode.

Figure 7-22. Synchronous Multiple Write (Burst Write) in Address/Data-Multiplexed Mode

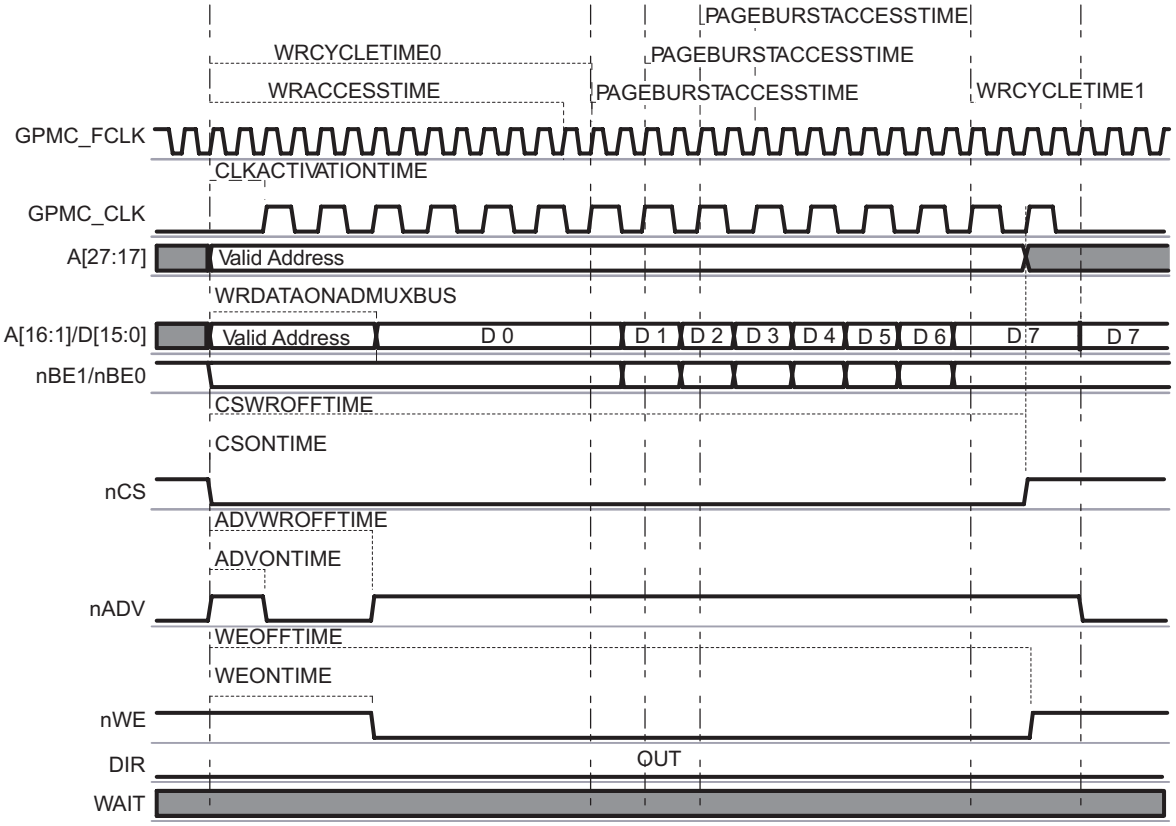


Figure 7-23 shows the same synchronous burst write access when the chip-select is configured in address/address/data-multiplexed (AAD-multiplexed) mode.

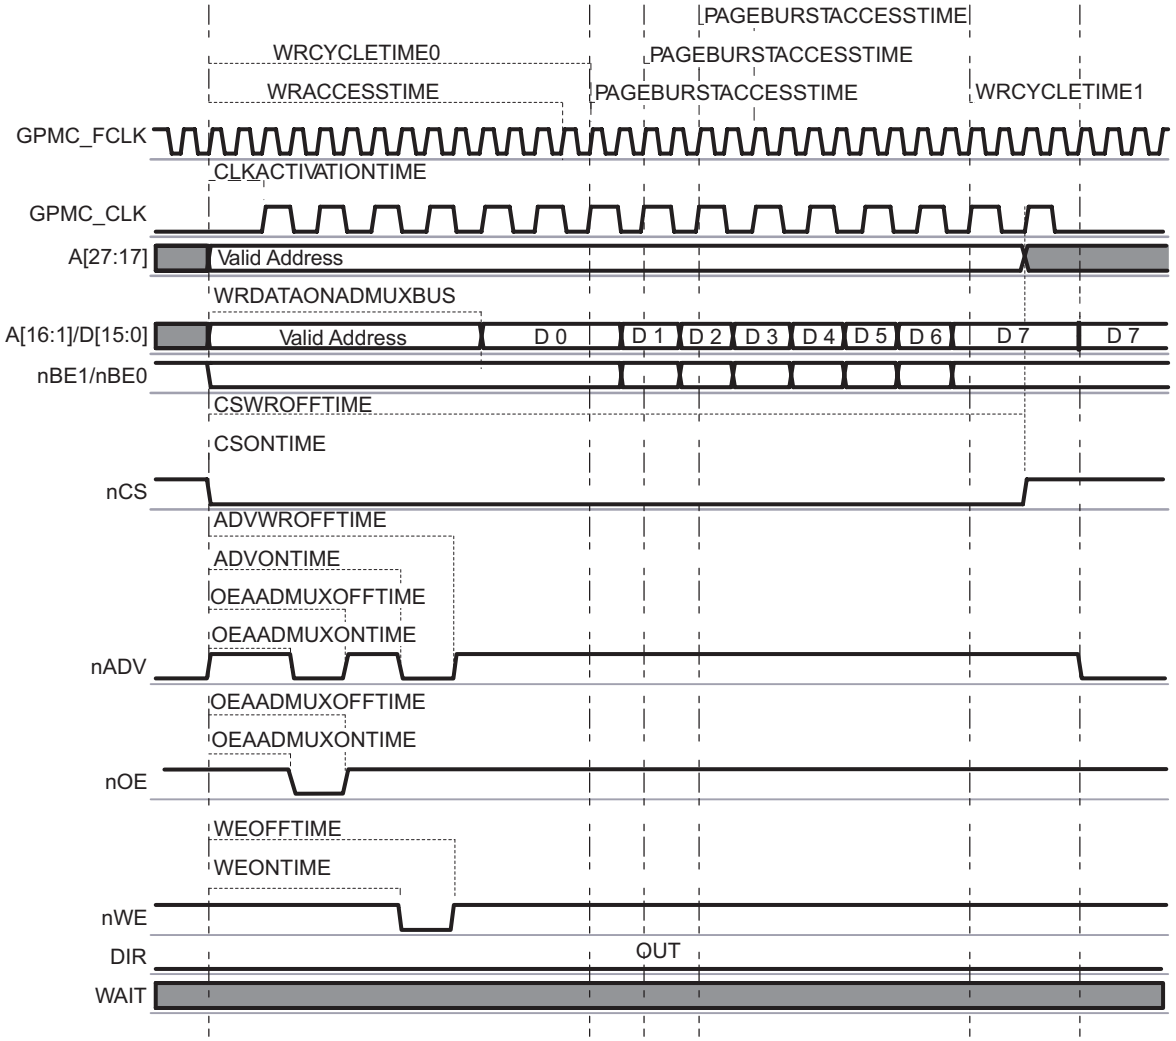
Copyright © 2011, Texas Instruments Incorporated

Figure 7-23. Synchronous Multiple Write (Burst Write) in Address/Address/Data-Multiplexed Mode



The first data of the burst is driven on the A/D bus at GPMC_CONFIG6_i[19:16] WRDATAONADMUXBUS.

When WRACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to the GPMC_CONFIG5_i[27-24] PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until OEn assertion time. For details, see Section 7.1.3.3.8.2.3.

- Chip-select signal CSn
  - CSn assertion time is controlled by the GPMC_CONFIG2_i[3-0] CSONTIME field and ensures address setup time to CSn assertion.
  - CSn deassertion time controlled by the GPMC_CONFIG2_i[20-16] CSWROFFTIME field and ensures address hold time to CSn deassertion.
- Address valid signal ADVn
  - ADVn assertion time is controlled by the GPMC_CONFIG3_i[3-0] ADVONTIME field.
  - ADVn deassertion time is controlled by the GPMC_CONFIG3_i[20-16] ADVWROFFTIME field.

Copyright © 2011, Texas Instruments Incorporated

- Write enable signal WEn
  - WEn assertion indicates a read cycle.
  - WEn assertion time is controlled by the GPMC_CONFIG4_i[19-16] WEONTIME field.
  - WEn deassertion time is controlled by the GPMC_CONFIG4_i[28-24] WEOFFTIME field.

  The WEn falling edge must not be used to control the time when the burst first data is driven in the address/data bus because some new devices require the WEn signal at low during the address phase.
- Direction signal DIR is OUT during the entire access.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with OEn driven low. The second phase for LSB address is qualified with OEn driven high. The address phase ends at WEn assertion time.

The CSn and DIR signals are controlled as detailled above.

- Address valid signal ADVn is asserted and deasserted twice during a read transaction
  - ADVn first assertion time is controlled by the GPMC_CONFIG3_i[[6-4] ADVAADMUXONTIME field.
  - ADVn first deassertion time is controlled by the GPMC_CONFIG3_i[[26-24] ADVAADMUXRDOFFTIME field.
  - ADVn second assertion time is controlled by the GPMC_CONFIG3_i[[3-0] ADVONTIME field.
  - ADVn second deassertion time is controlled by the GPMC_CONFIG3_i[[12-8] ADVRDOFFTIME field.
- Output Enable signal OEn is asserted and deasserted twice during a read transaction (OEn second assertion indicates a read cycle)
  - OEn first assertion time is controlled by the GPMC_CONFIG4_i[[6-4] OEAADMUXONTIME field.
  - OEn first deassertion time is controlled by the GPMC_CONFIG4_i[15-13] OEAADMUXOFFTIME field.
  - OEn second assertion time is controlled by the GPMC_CONFIG4_i[3-0] OEONTIME field.
  - OEn second deassertion time is controlled by the GPMC_CONFIG4_i[12-8] OEOFFTIME field.

First write data is driven by the GPMC at GPMC_CONFIG6_i[19-16] WRDATAONADMUXBUS, when in address/data mux configuration. The next write data of the burst is driven on the bus at WRACCESSTIME + 1 during GPMC_CONFIG5_i[27-24] PAGEBURSTACCESSTIME GPMC_FCLK cycles. The last data of the synchronous burst write is driven until GPMC_CONFIG5_i[12-8] WRCYCLETIME completes.

- WRACCESSTIME is defined in the GPMC_CONFIG6_i[28-24] register.
- The PAGEBURSTACCESSTIME parameter must be set accordingly with GPMCFCLKDIVIDER and the memory-device internal configuration.

Total access time GPMC_CONFIG5_i[12-8] WRCYCLETIME corresponds to WRACCESSTIME plus the address hold time from CSn deassertion. In Figure 7-23 the WRCYCLETIME programmed value equals WRCYCLETIME0 + WRCYCLETIME1. WRCYCLETIME0 and WRCYCLETIME1 delays are not actual parameters and are only a graphical representation of the full WRCYCLETIME value.

After a write operation, if no other access (read or write) is pending, the data bus keeps the previous value. See Section 7.1.3.3.9.10.

7.1.3.3.10.3 Asynchronous and Synchronous Accesses in Nonmultiplexed Mode

Page mode is only available in non-multiplexed mode.

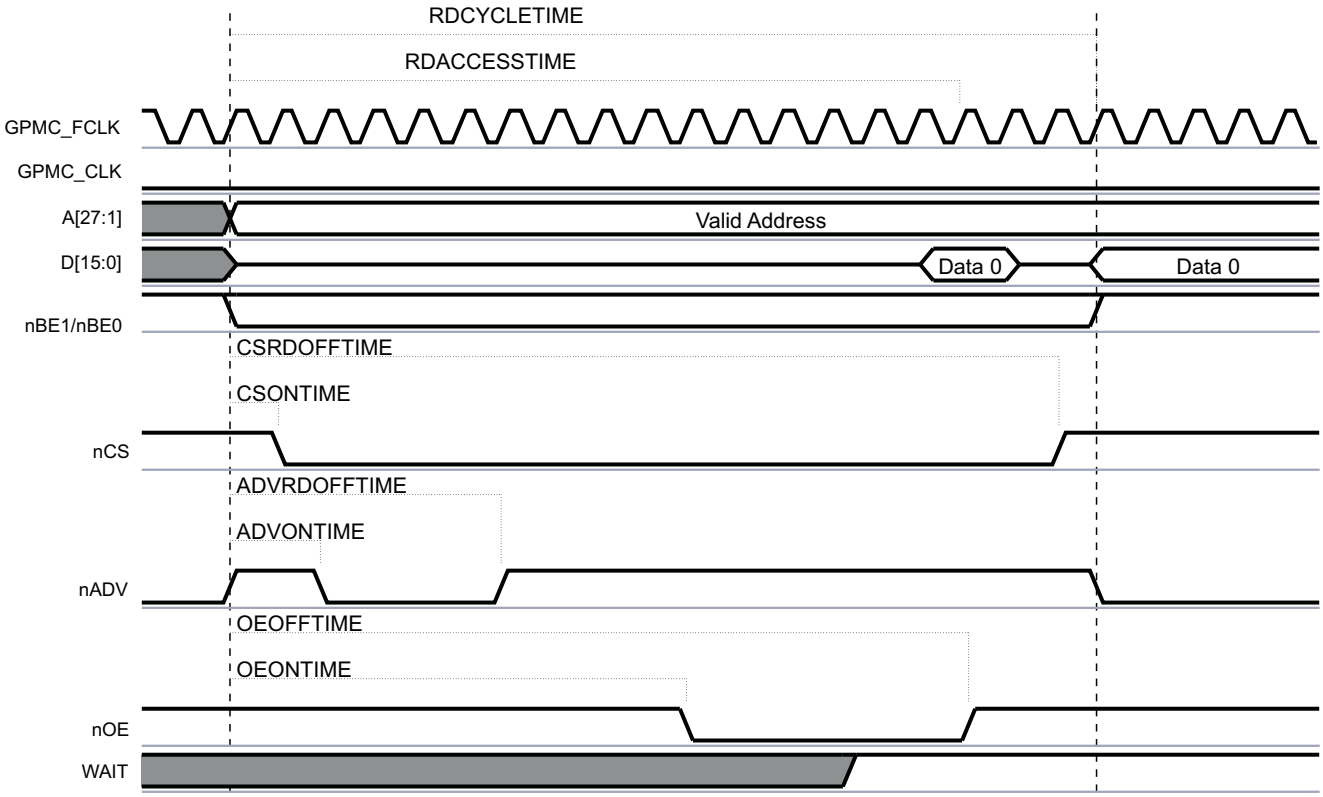
- Asynchronous single read operation on a nonmultiplexed device
- Asynchronous single write operation on a nonmultiplexed device
- Asynchronous multiple (page mode) read operation on a nonmultiplexed device
- Synchronous operations on a nonmultiplexed device

Copyright © 2011, Texas Instruments Incorporated

7.1.3.3.10.3.1 Asynchronous Single Read Operation on a Nonmultiplexed Device

Figure 7-24 shows an asynchronous single read operation on a nonmultiplexed device.

Figure 7-24. Asynchronous Single Read on an Address/Data-Nonmultiplexed Device



The 27-bit address is driven onto the address bus A[27:1] and the 16-bit data is driven onto the data bus D[15:0].

Read data is latched at GPMC_CONFIG1_5[20-16] RDACCESSTIME completion time. The end of the access is defined by the GPMC_CONFIG1_5[4-0] RDCYCLETIME parameter.

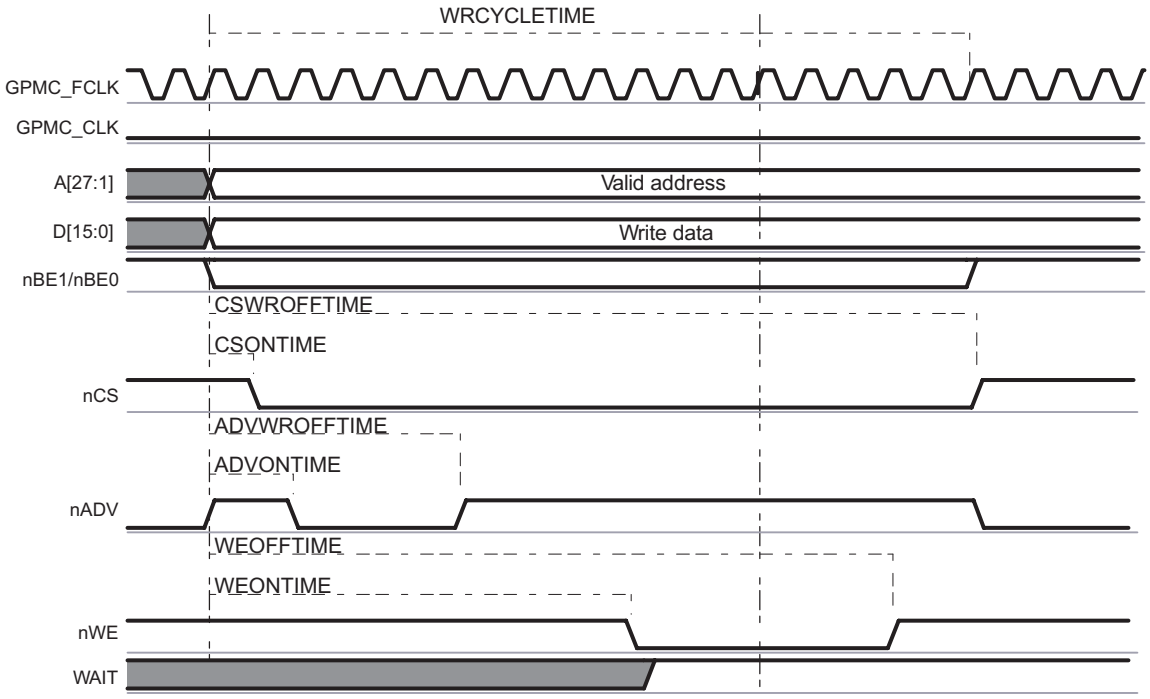
CSn, ADVn, OEn and DIR signals are controlled in the same way as address/data multiplexed accesses, see Section 7.1.3.3.10.1.1.2.

Copyright © 2011, Texas Instruments Incorporated

7.1.3.3.10.3.2 Asynchronous Single Write Operation on a Nonmultiplexed Device

Figure 7-25 shows an asynchronous single write operation on a nonmultiplexed device.

Figure 7-25. Asynchronous Single Write on an Address/Data-Nonmultiplexed Device



The 27-bit address is driven onto the address bus A[27:1] and the 16-bit data is driven onto the data bus D[15:0].

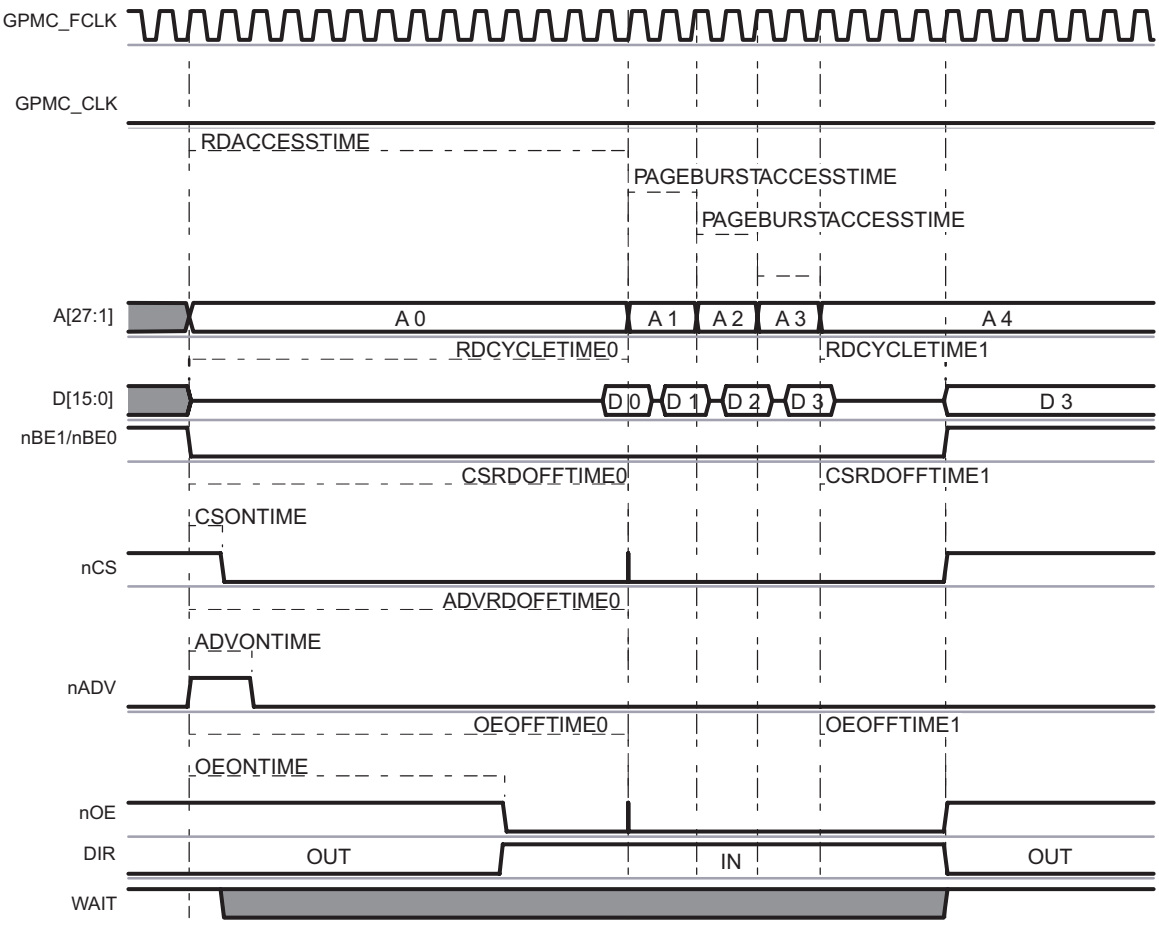
CSn, ADVn, WEn and DIR signals are controlled in the same way as address/data multiplexed accesses, see Section 7.1.3.3.10.1.1.3.

Copyright © 2011, Texas Instruments Incorporated

7.1.3.3.10.3.3 Asynchronous Multiple (Page Mode) Read Operation on a Nonmultiplexed Device

Figure 7-26 shows an asynchronous multiple read operation on a Nonmultiplexed Device, in which two word32 host read accesses to the GPMC are split into one multiple (page mode of 4 word16) read access to the attached device.

Figure 7-26. Asynchronous Multiple (Page Mode) Read



The WAIT signal is active low.

CSn, ADVn, OEn and DIR signals are controlled in the same way as address/data multiplexed accesses, see Section 7.1.3.3.10.1.1.2.

When RDACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

Read data is latched at GPMC_CONFIG5_i[20-16] RDACCESSTIME completion time. The end of the access is defined by the GPMC_CONFIG5_i[4-0] RDCYCLETIME parameter.

During consecutive accesses, the GPMC increments the address after each data read completes.

Delay between successive read data in the page is controlled by the GPMC_CONFIG5_i[27-24] PAGEBURSTACCESSTIME parameter. Depending on the device page length, the GPMC can control device page crossing during a burst request and insert initial RDACCESSTIME latency. Note that page crossing is only possible with a new burst access, meaning a new initial access phase is initiated.

Total access time RDCYCLETIME corresponds to RDACCESSTIME plus the address hold time starting from the CSn deassertion.

- The read cycle time is defined in the GPMC_CONFIG5_i[4-0] RDCYCLETIME field.
- In Figure 7-26, the RDCYCLETIME programmed value equals RDCYCLETIME0 (before paged accesses) + RDCYCLETIME1 (after paged accesses).

Copyright © 2011, Texas Instruments Incorporated

7.1.3.3.10.3.4 Synchronous Operations on a Nonmultiplexed Device

All information for this section is equivalent to similar operations for address/data- or AAD-multiplexed accesses. The only difference resides in the address phase. See Section 7.1.3.6.

7.1.3.3.10.4 Page and Burst Support

Each chip-select can be configured to process system single or burst requests into successive single accesses or asynchronous page/synchronous burst accesses, with appropriate access size adaptation.

Depending on the external device page or burst capability, read and write accesses can be independently configured through the GPMC. The GPMC_CONFIG1_i[30] READMULTIPLE and GPMC_CONFIG1_i[28] WRITMULTIPLE bits are associated with the READTYPE and WRITETYPE parameters.

- Asynchronous write page mode is not supported.
- 8-bit wide device support is limited to nonburstable devices (READMULTIPLE and WRITEMULTIPLE are ignored).
- Not applicable to NAND device interfacing.

7.1.3.3.10.5 System Burst Versus External Device Burst Support

The device system can issue the following requests to the GPMC:

- Byte, 16-bit word, 32-bit word requests (byte enable controlled). This is always a single request from the interconnect point of view.
- Incrementing fixed-length bursts of two words, four words, and eight words
- Wrapped (critical word access first) fixed-length burst of two, four, or eight words

To process a system request with the optimal protocol, the READMULTIPLE (and READTYPE) and WRITEMULTIPLE (and WRITETYPE) parameters must be set according to the burstable capability (synchronous or asynchronous) of the attached device.

The GPMC access engine issues only fixed-length burst. The maximum length that can be issued is defined per CS by the GPMC_CONFIG1_i[24-23] ATTACHEDDEVICEPAGELENGTH field. When the ATTACHEDDEVICEPAGELENGTH value is less than the system burst request length (including the appropriate access size adaptation according to the device width), the GPMC splits the system burst request into multiple bursts. Within the specified 4-, 8-, or 16-word value, the ATTACHEDDEVICEPAGELENGTH field value must correspond to the maximum-length burst supported by the memory device configured in fixed-length burst mode (as opposed to continuous burst mode).

To get optimal performance from memory devices that natively support 16 Word16-length-wrapping burst capability (critical word access first), the ATTACHEDDEVICEPAGELENGTH parameter must be set to 16 words and the GPMC_CONFIG1_i[31] WRAPBURST bit must be set to 1. Similarly DEVICEPAGELENGTH is set to 4 and 8 for memories supporting respectively 4 and 8 Word16-length-wrapping burst.

When the memory device does not offer (or is not configured to offer) native 16 Word16-length-wrapping burst, the WRAPBURST parameter must be cleared, and the GPMC access engine emulates the wrapping burst by issuing the appropriate burst sequences according to the ATTACHEDDEVICEPAGELENGTH value.

When the memory device does not support native-wrapping burst, there is usually no difference in behavior between a fixed burst length mode and a continuous burst mode configuration (except for a potential power increase from a memory-speculative data prefetch in a continuous burst read). However, even though continuous burst mode is compatible with GPMC behavior, because the GPMC access engine issues only fixed-length burst and does not benefit from continuous burst mode, it is best to configure the memory device in fixed-length burst mode.

The memory device maximum-length burst (configured in fixed-length burst wrap or nonwrap mode) usually corresponds to the memory device data buffer size. Memory devices with a minimum of 16 half-word buffers are the most appropriate (especially with wrap support), but memory devices with smaller buffer size (4 or 8) are also supported, assuming that the GPMC_CONFIG1_i[24-23] ATTACHEDDEVICEPAGELENGTH field is set accordingly to 4 or 8 words.

Copyright © 2011, Texas Instruments Incorporated

The device system issues only requests with addresses or starting addresses for nonwrapping burst requests; that is, the request size boundary is aligned. In case of an eight-word-wrapping burst, the wrapping address always occurs on the eight-words boundary. As a consequence, all words requested must be available from the memory data buffer when the buffer size is equal to or greater than the ATTACHEDDEVICEPAGELENGTH value. This usually means that data can be read from or written to the buffer at a constant rate (number of cycles between data) without wait states between data accesses. If the memory does not behave this way (nonzero wait state burstable memory), wait-pin monitoring must be enabled to dynamically control data-access completion within the burst.

When the system burst request length is less than the ATTACHEDDEVICEPAGELENGTH value, the GPMC proceeds with the required accesses.

7.1.3.3.11 pSRAM Access Specificities

pSRAM devices are SRAM-pin-compatible low-power memories that contain a self-refreshed DRAM memory array. The GPMC_CONFIG1_i[[11-10] DEVICETYPE field shall be cleared to 0b00.

The pSRAM devices uses the NOR protocol. It support the following operations:

- Asynchronous single read
- Asynchronous page read
- Asynchronous single write
- Synchronous single read and write
- Synchronous burst read
- Synchronous burst write (not supported by NOR Flash memory)

pSRAM devices must be powered up and initialized in a predefined manner according to the specifications of the attached device.

pSRAM devices can be programmed to use either mode: fixed or variable latency. pSRAM devices can either automatically schedule autorefresh operations, which force the GPMC to use its WAIT signal capability when read or write operations occur during an internal self-refresh operation, or pSRAM devices automatically include the autorefresh operation in the access time. These devices do not require additional WAIT signal capability or a minimum CSn high pulse width between consecutive accesses to ensure that the correct internal refresh operation is scheduled.

7.1.3.3.12 NAND Access Description

NAND (8-bit and 16-bit) memory devices using a standard NAND asynchronous address/data-multiplexing scheme can be supported on any chip-select with the appropriate asynchronous configuration settings

As for any other type of memory compatible with the GPMC interface, accesses to a chip-select allocated to a NAND device can be interleaved with accesses to chip-selects allocated to other external devices. This interleaved capability limits the system to *chip enable don't care* NAND devices, because the chip-select allocated to the NAND device must be de-asserted if accesses to other chip-selects are requested.

7.1.3.3.12.1 NAND Memory Device in Byte or 16-Bit Word Stream Mode

NAND devices require correct command and address programming before data array read or write accesses. The GPMC does not include specific hardware to translate a random address system request into a NAND-specific multiphase access. In that sense, GPMC NAND support, as opposed to random memory-map device support, is data-stream-oriented (byte or 16-bit word).

The GPMC NAND programming model relies on a software driver for address and command formatting with the correct data address pointer value according to the block and page structure. Because of NAND structure and protocol interface diversity, the GPMC does not support automatic command and address phase programming, and software drivers must access the NAND device ID to ensure that correct command and address formatting are used for the identified device.

NAND device data read and write accesses are achieved through an asynchronous read or write access. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Copyright © 2011, Texas Instruments Incorporated

Any chip-select region can be qualified as a NAND region to constrain the ADVn_ALE signal as Address Latch Enable (ALE active high, default state value at low) during address program access, and the BE0n_CLE signal as Command Latch Enable (CLE active high, default state value at low) during command program access. GPMC address lines are not used (the previous value is not changed) during NAND access.

7.1.3.3.12.1.1 Chip-Select Configuration for NAND Interfacing in Byte or Word Stream Mode

The GPMC_CONFIG7_i register associated with a NAND device region interfaced in byte or word stream mode can be initialized with a minimum size of 16 Mbytes, because any address location in the chip-select memory region can be used to access a NAND data array. The NAND Flash protocol specifies an address sequence where address bits are passed through the data bus in a series of write accesses with the ALE pin asserted. After this address phase, all operations are streamed and the system requests address is irrelevant.

To allow correct command, address, and data-access controls, the GPMC_CONFIG1_i register associated with a NAND device region must be initialized in asynchronous read and write modes with the parameters shown in Table 7-11. Failure to comply with these settings corrupts the NAND interface protocol.

The GPMC_CONFIG1_i to GPMC_CONFIG4_i register associated with a NAND device region must be initialized with the correct control-signal timing value according to the NAND device timing parameters.

Table 7-11. Chip-Select Configuration for NAND Interfacing

Bit Field	Register	Value	Comments
WRAPBURST	GPMC_CONFIG1_i	0	No wrap
READMULTIPLE	GPMC_CONFIG1_i	0	Single access
READTYPE	GPMC_CONFIG1_i	0	Asynchronous mode
WRITEMULTIPLE	GPMC_CONFIG1_i	0	Single access
WRITETYPE	GPMC_CONFIG1_i	0	Asynchronous mode
CLKACTIVATIONTIME	GPMC_CONFIG1_i	0b00	
ATTACHEDDEVICEPAGELENGTH	GPMC_CONFIG1_i	Don't care	Single-access mode
WAITREADMONITORING	GPMC_CONFIG1_i	0	Wait not monitored by GPMC access engine
WAITWRITEMONITORING	GPMC_CONFIG1_i	0	Wait not monitored by GPMC access engine
WAITMONITORINGTIME	GPMC_CONFIG1_i	Don't care	Wait not monitored by GPMC access engine
WAITPINSELECT	GPMC_CONFIG1_i		Select which wait is monitored by edge detectors
DEVICESIZE	GPMC_CONFIG1_i	0b00 or 0b01	8- or 16-bit interface
DEVICETYPE	GPMC_CONFIG1_i	0b10	NAND device in stream mode
MUXADDDATA	GPMC_CONFIG1_i	0b00	Nonmultiplexed mode

7.1.3.3.12.1.2 NAND Device Command and Address Phase Control

NAND devices require multiple address programming phases. The MPU software driver is responsible for issuing the correct number of command and address program accesses, according to the device command set and the device address-mapping scheme.

NAND device-command and address-phase programming is achieved through write requests to the GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i register locations with the correct command and address values. These locations are mapped in the associated chip-select register region. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Copyright © 2011, Texas Instruments Incorporated

Command and address values are not latched during the access and cannot be read back at the register location.

- Only write accesses must be issued to these locations, but the GPMC does not discard any read access. Accessing a NAND device with OEn and CLE or ALE asserted (read access) can produce undefined results.
- Write accesses to the GPMC_NAND_COMMAND_i register location and to the GPMC_NAND_ADDRESS_i register location must be posted for faster operations. The GPMC_CONFIG[0] NANDFORCEPOSTEDWRITE bit enables write accesses to these locations as posted, even if they are defined as nonposted.

A write buffer is used to store write transaction information before the external device is accessed:

- Up to eight consecutive posted write accesses can be accepted and stored in the write buffer.
- For nonposted write, the pipeline is one deep.
- A GPMC_STATUS[0] EMPTYWRITEBUFFERSTATUS bit stores the empty status of the write buffer.

The GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i registers are 32-bit word locations, which means any 32-bit word or 16-bit word access is split into 4- or 2-byte accesses if an 8-bit wide NAND device is attached. For multiple-command phase or multiple-address phase, the software driver can use 32-bit word or 16-bit word access to these registers, but it must account for the splitting and little-endian ordering scheme. When only one byte command or address phase is required, only byte write access to a GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i can be used, and any of the four byte locations of the registers are valid.

The same applies to GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i 32-bit word write access to a 16-bit wide NAND device (split into two 16-bit word accesses). In the case of a 16-bit word write access, the MSByte of the 16-bit word value must be set according to the NAND device requirement (usually 0). Either 16-bit word location or any one of the four byte locations of the registers is valid

7.1.3.3.12.1.3 Command Latch Cycle

Writing data at the GPMC_NAND_COMMAND_i location places the data as the NAND command value on the bus, using a regular asynchronous write access.

- CSn[i] is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- CLE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.
- WE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- ALE and REn (OEn) are maintained inactive.

Figure 7-27 shows the NAND command latch cycle.

CLE is shared with the BE0n output signal and has an inverted polarity from BE0n. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, BE0n (also BE1n) must not toggle, because it is shared with CLE.

NAND Flash memories do not use byte enable signals at all.

Figure 7-27. NAND Command Latch Cycle

7.1.3.3.12.1.4 Address Latch Cycle

Writing data at the GPMC_NAND_ADDRESS_i location places the data as the NAND partial address value on the bus, using a regular asynchronous write access.

- CSn is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- ALE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.
- WEn is controlled by the WEONTIME and WEOFFTIME timing parameters.
- CLE and REn (OEn) are maintained inactive.

Figure 7-28 shows the NAND address latch cycle.

ALE is shared with the ADVn output signal and has an inverted polarity from ADVn. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, ALE is kept stable.

Figure 7-28. NAND Address Latch Cycle

7.1.3.3.12.1.5 NAND Device Data Read and Write Phase Control in Stream Mode

NAND device data read and write accesses are achieved through a read or write request to the chip-select-associated memory region at any address location in the region or through a read or write request to the GPMC_NAND_DATA_i location mapped in the chip-select-associated control register region. GPMC_NAND_DATA_i is not a true register, but an address location to enable REn or WEn signal control. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

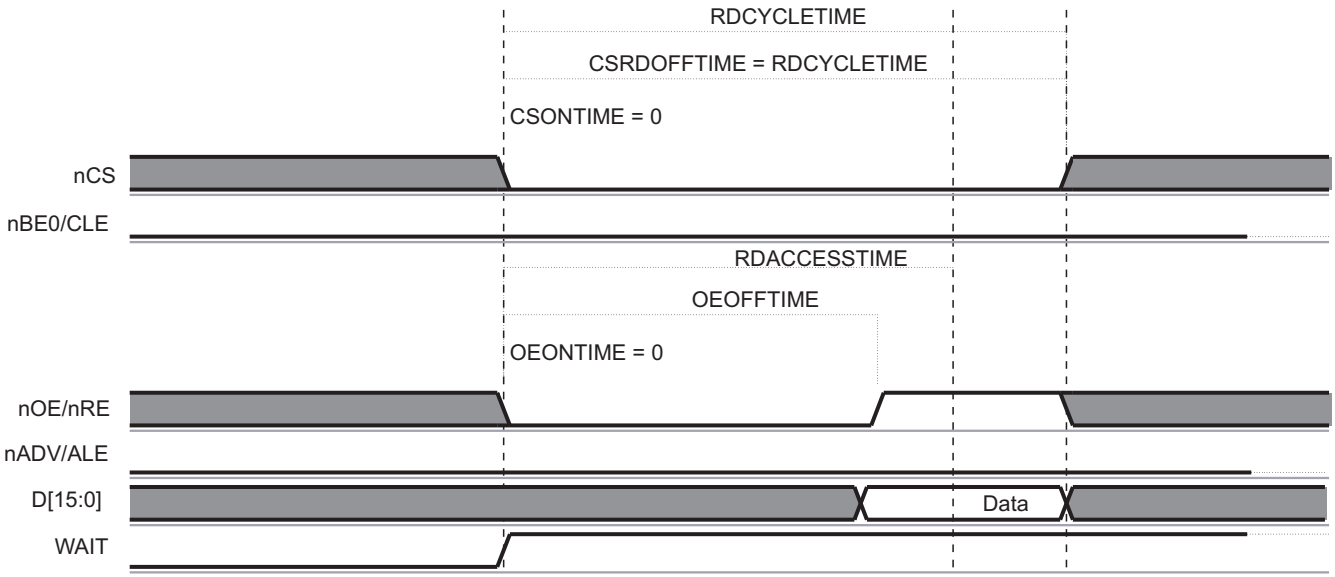
Reading data from the GPMC_NAND_DATA_i location or from any location in the associated chip-select memory region activates an asynchronous read access.

- CSn is controlled by the CSONTIME and CSRDOFFTIME timing parameters.
- REn is controlled by the OEONTIME and OEOFFTIME timing parameters.
- To take advantage of REn high-to-data invalid minimum timing value, the RDACCESSTIME can be set so that data are effectively captured after REn deassertion. This allows optimization of NAND read access cycle time completion. For optimal timing parameter settings, see the NAND device and the device IC timing parameters.

ALE, CLE, and WEn are maintained inactive.

Figure 7-29 shows the NAND data read cycle.

Figure 7-29. NAND Data Read Cycle



Writing data to the GPMC_NAND_DATA_i location or to any location in the associated chip-select memory region activates an asynchronous write access.

- CSn is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- WEn is controlled by the WEONTIME and WEOFFTIME timing parameters.
- ALE, CLE, and REn (OEn) are maintained inactive.

Figure 7-30 shows the NAND data write cycle.

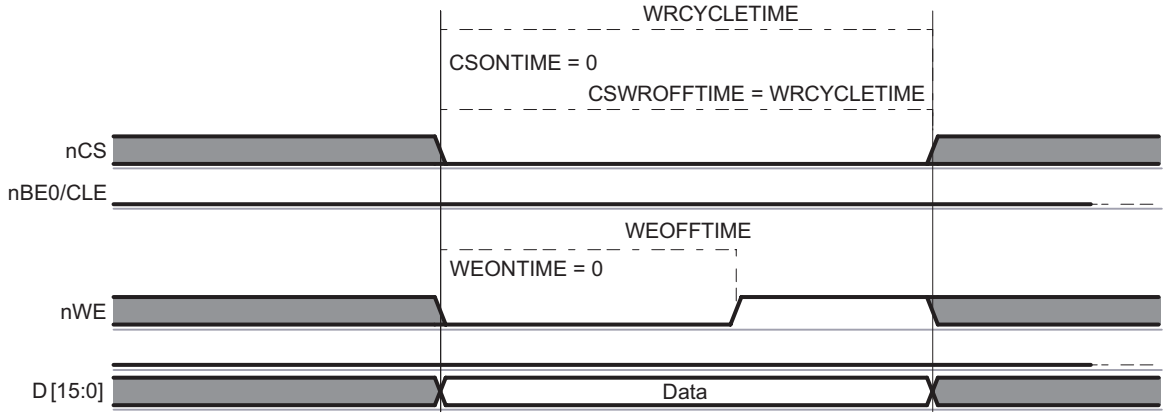
Figure 7-30. NAND Data Write Cycle



7.1.3.3.12.1.6 NAND Device General Chip-Select Timing Control Requirement

For most NAND devices, read data access time is dominated by CSn-to-data-valid timing and has faster REn-to-data-valid timing. Successive accesses with CSn deassertions between accesses are affected by this timing constraint. Because accesses to a NAND device can be interleaved with other chip-select accesses, there is no certainty that CSn always stays low between two accesses to the same chip-select. Moreover, an CSn deassertion time between the same chip-select NAND accesses is likely to be required as follows: the CSn deassertion requires programming CYCLETIME and RDACCESSTIME according to the CSn-to-data-valid critical timing.

To get full performance from NAND read and write accesses, the prefetch engine can dynamically reduce RDCYCLETIME, WRCYCLETIME, RDACCESSTIME, WRACCESSTIME, CSRDOFFTIME, CSWROFFTIME, ADVRDOFFTIME, ADVWROFFTIME, OEOFFTIME, and WEOFFTIME on back-to-back NAND accesses (to the same memory) and suppress the minimum CSn high pulse width between accesses. For more information about optimal prefetch engine access, see Section 7.1.3.3.12.4.

Some NAND devices require minimum write-to-read idle time, especially for device-status read accesses following status-read command programming (write access). If such write-to-read transactions are used, a minimum CSn high pulse width must be set. For this, CYCLE2CYCLESAMECSEN and CYCLE2CYCLEDELAY must be set according to the appropriate timing requirement to prevent any timing violation.

NAND devices usually have an important REn high to data bus in tristate mode. This requires a bus turnaround setting (BUSTURNAROUND = 1), so that the next access to a different chip-select is delayed until the BUSTURNAROUND delay completes. Back-to-back NAND read accesses to the same NAND Flash are not affected by the programmed bus turnaround delay.

7.1.3.3.12.1.7 Read and Write Access Size Adaptation

7.1.3.3.12.1.7.1 8-Bit Wide NAND Device

Host 16-bit word and 32-bit word read and write access requests to a chip-select associated with an 8-bit wide NAND device are split into successive read and write byte accesses to the NAND memory device. Byte access is ordered according to little-endian organization. A NAND 8-bit wide device must be interfaced on the D0D7 interface bus lane. GPMC data accesses are justified on this bus lane when the chip-select is associated with an 8-bit wide NAND device.

7.1.3.3.12.1.7.2 16-Bit Wide NAND Device

Host 32-bit word read and write access requests to a chip-select associated with a 16-bit wide NAND device are split into successive read and write 16-bit word accesses to the NAND memory device. 16-bit word access is ordered according to little-endian organization.

Copyright © 2011, Texas Instruments Incorporated

Host byte read and write access requests to a 16-bit wide NAND device are completed as 16-bit accesses on the device itself, because there is no byte-addressing capability on 16-bit wide NAND devices. This means that the NAND device address pointer is incremented on a 16-bit word basis and not on a byte basis. For a read access, only the requested byte is given back to the host, but the remaining byte is not stored or saved by the GPMC, and the next byte or 16-bit word read access gets the next 16-bit word NAND location. For a write access, the invalid byte part of the 16-bit word is driven to FF, and the next byte or 16-bit word write access programs the next 16-bit word NAND location.

Generally, byte access to a 16-bit wide NAND device should be avoided, especially when ECC calculation is enabled. 8-bit or 16-bit ECC-based computations are corrupted by a byte read to a 16-bit wide NAND device, because the nonrequested byte is considered invalid on a read access (not captured on the external data bus; FF is fed to the ECC engine) and is set to FF on a write access.

Host requests (read/write) issued in the chip-select memory region are translated in successive single or split accesses (read/write) to the attached device. Therefore, incrementing 32-bit burst requests are translated in multiple 32-bit sequential accesses following the access adaptation of the 32-bit to 8- or 16-bit device.

7.1.3.3.12.2 NAND Device-Ready Pin

The NAND memory device provides a ready pin to indicate data availability after a block/page opening and to indicate that data programming is complete. The ready pin can be connected to one of the WAIT GPMC input pins; data read accesses must not be tried when the ready pin is sampled inactive (device is not ready) even if the associated chip-select WAITREADMONITORING bit field is set. The duration of the NAND device busy state after the block/page opening is so long (up to 50 µs) that accesses occurring when the ready pin is sampled inactive can stall GPMC access and eventually cause a system time-out.

If a read access to a NAND flash is done using the wait monitoring mode, the device is blocked during a page opening, and so is the GPMC. If the correct settings are used, other chip-selects can be used while the memory processes the page opening command.

To avoid a time-out caused by a block/page opening delay in NAND flash, disable the wait pin monitoring for read and write accesses (that is, set the GPMC_CONFIG1_i[[21] WAITWRITEMONITORING and GPMC_CONFIG1_i[[22] WAITREADMONITORING bits to 0 and use one of the following methods instead:

- Use software to poll the WAITnSTATUS bit (n = 0 to 1) of the GPMC_STATUS register.
- Configure an interrupt that is generated on the WAIT signal change (through the GPMC_IRQENABLE [11-8]bits).

Even if the READWAITMONITORING bit is not set, the external memory nR/B pin status is captured in the programmed WAIT bit in the GPMC_STATUS register.

The READWAITMONITORING bit method must be used for other memories than NAND flash, if they require the use of a WAIT signal.

7.1.3.3.12.2.1 Ready Pin Monitored by Software Polling

The ready signal state can be monitored through the GPMC_STATUS WAITxSTATUS bit (x = 0 or 1). The software must monitor the ready pin only when the signal is declared valid. Refer to the NAND device timing parameters to set the correct software temporization to monitor ready only after the invalid window is complete from the last read command written to the NAND device.

7.1.3.3.12.2.2 Ready Pin Monitored by Hardware Interrupt

Each gpmc_wait input pin can generate an interrupt when a wait-to-no-wait transition is detected. Depending on whether the GPMC_CONFIG WAITxPINPOLARITY bits (x = 0 or 1) is active low or active high, the wait-to-no-wait transition is a low-to-high external WAIT signal transition or a high-to-low external WAIT signal transition, respectively.

The wait transition pin detector must be cleared before any transition detection. This is done by writing 1

Copyright © 2011, Texas Instruments Incorporated

to the WAITxEDGEDETECTIONSTATUS bit (x = 0 or 1) of the GPMC_IRQSTATUS register according to the gpmc_wait pin used for the NAND device-ready signal monitoring. To detect a wait-to-no-wait transition, the transition detector requires a wait active time detection of a minimum of two GPMC_FCLK cycles. Software must incorporate precautions to clear the wait transition pin detector before wait (busy) time completes.

A wait-to-no-wait transition detection can issue a GPMC interrupt if the WAITxEDGEDETECTIONENABLE bit in the GPMC_IRQENABLE register is set and if the WAITxEDGEDETECTIONSTATUS bit field in the GPMC_IRQSTATUS register is set.

The WAITMONITORINGTIME field does not affect wait-to-no-wait transition time detection.

It is also possible to poll the WAITxEDGEDETECTIONSTATUS bit field in the GPMC_IRQSTATUS register according to the gpmc_wait pin used for the NAND device ready signal monitoring.

7.1.3.3.12.3 ECC Calculator

The General Purpose Memory Controller includes an Error Code Correction (ECC) calculator circuitry that enables on the fly ECC calculation during data read or data program (that is, write) operations. The page size supported by the ECC calculator in one calculation/context is 512 bytes.

The user can choose from two different algorithms with different error correction capabilities through the GPMC_ECC_CONFIG[16] ECCALGORITHM bit:

- Hamming code for 1-bit error code correction on 8- or 16-bit NAND Flash organized with page size greater than 512 bytes
- BCH (Bose-Chaudhurl-Hocquenghem) code for 4- to 16-bit error correction

The GPMC does not directly handle the error code correction itself. During writes, the GPMC computes parity bits. During reads, the GPMC provides enough information for the processor to correct errors without reading the data buffer all over again.

The Hamming code ECC is based on a 2-dimensional (row and column) bit parity accumulation. This parity accumulation is either accomplished on the programmed number of bytes or 16-bit words read from the memory device, or written to the memory device in stream mode.

Because the ECC engine includes only one accumulation context, it can be allocated to only one chip-select at a time through the GPMC_ECC_CONFIG[3-1] ECCCS bit field. Even if two CS use different ECC algorithms, one the Hamming code and the other a BCH code, they must define separate ECC contexts because some of the ECC registers are common to all types of algorithms.

7.1.3.3.12.3.1 Hamming Code

All references to Error Code Correction (ECC) in this subsection refer to the 1-bit error correction Hamming code.

The ECC is based on a two-dimensional (row and column) bit parity accumulation known as Hamming Code. The parity accumulation is done for a programmed number of bytes or 16-bit word read from the memory device or written to the memory device in stream mode.

There is no automatic error detection or correction, and it is the software NAND driver responsibility to read the multiple ECC calculation results, compare them to the expected code value, and take the appropriate corrective actions according to the error handling strategy (ECC storage in spare byte, error correction on read, block invalidation).

The ECC engine includes a single accumulation context. It can be allocated to a single designated chip-select at a time and parallel computations on different chip-selects are not possible. Since it is allocated to a single chip-select, the ECC computation is not affected by interleaved GPMC accesses to other chip-selects and devices. The ECC accumulation is sequentially processed in the order of data read from or written to the memory on the designated chip-select. The ECC engine does not differentiate read accesses from write accesses and does not differentiate data from command or status information. It is the software responsibility to make sure only relevant data are passed to the NAND flash memory while the ECC computation engine is active.

Copyright © 2011, Texas Instruments Incorporated

The starting NAND page location must be programmed first, followed by an ECC accumulation context reset with an ECC enabling, if required. The NAND device accesses discussed in the following sections must be limited to data read or write until the specified number of ECC calculations is completed.

7.1.3.3.12.3.1.1 ECC Result Register and ECC Computation Accumulation Size

The GPMC includes up to nine ECC result registers (GPMC_ECCj_RESULT, j = 1 to 9) to store ECC computation results when the specified number of bytes or 16-bit words has been computed.

The ECC result registers are used sequentially; one ECC result is stored in one ECC result register on the list, the next ECC result is stored in the next ECC result register on the list, and so forth, until the last ECC computation. The value of the GPMC_ECCj_RESULT register value is valid only when the programmed number of bytes or 16-bit words has been accumulated, which means that the same number of bytes or 16-bit words has been read from or written to the NAND device in sequence.

The GPMC_ECC_CONTROL[3-0] ECCPOINTER field must be set to the correct value to select the ECC result register to be used first in the list for the incoming ECC computation process. The ECCPointer can be read to determine which ECC register is used in the next ECC result storage for the ongoing ECC computation. The value of the GPMC_ECCj_RESULT register (j = 1 to 9) can be considered valid when ECCPOINTER equals j + 1. When the GPMC_ECCj_RESULT (where j = 9) is updated, ECCPOINTER is frozen at 10, and ECC computing is stopped (ECCENABLE = 0).

The ECC accumulator must be reset before any ECC computation accumulation process. The GPMC_ECC_CONTROL[8] ECCCLEAR bit must be set to 1 (nonpersistent bit) to clear the accumulator and all ECC result registers.

For each ECC result (each register, j = 1 to 9), the number of bytes or 16-bit words used for ECC computing accumulation can be selected from between two programmable values.

The ECCjRESULTSIZE bits (j = 1 to 9) in the GPMC_ECC_SIZE_CONFIG register select which programmable size value (ECCSIZE0 or ECCSIZE1) must be used for this ECC result (stored in GPMC_ECCj_RESULT register).

The ECCSIZE0 and ECCSIZE1 fields allow selection of the number of bytes or 16-bit words used for ECC computation accumulation. Any even values from 2 to 512 are allowed.

Flexibility in the number of ECCs computed and the number of bytes or 16-bit words used in the successive ECC computations enables different NAND page error-correction strategies. Usually based on 256 or 512 bytes and on 128 or 256 16-bit word, the number of ECC results required is a function of the NAND device page size. Specific ECC accumulation size can be used when computing the ECC on the NAND spare byte.

For example, with a 2 Kbyte data page 8-bit wide NAND device, eight ECCs accumulated on 256 bytes can be computed and added to one extra ECC computed on the 24 spare bytes area where the eight ECC results used for comparison and correction with the computed data page ECC are stored. The GPMC then provides nine GPMC_ECCj_RESULT registers (j= 1 to 9) to store the results. In this case, ECCSIZE0 is set to 256, and ECCSIZE1 is set to 24; the ECC[1-8]RESULTSIZE bits are cleared to 0, and the ECC9RESULTSIZE bit is set to 1.

7.1.3.3.12.3.1.2 ECC Enabling

The GPMC_ECC_CONFIG[3-1] ECCCS field selects the allocated chip-select. The GPMC_ECC_CONFIG[0] ECCENABLE bit enables ECC computation on the next detected read or write access to the selected chip-select.

The ECCPOINTER, ECCCLEAR, ECCSIZE, ECCjRESULTSIZE (where j = 1 to 9), ECC16B, and ECCCS fields must not be changed or cleared while an ECC computation is in progress.

The ECC accumulator and ECC result register must not be changed or cleared while an ECC computation is in progress.

Table 7-12 describes the ECC enable settings.

Copyright © 2011, Texas Instruments Incorporated

Table 7-12. ECC Enable Settings

Bit Field	Register	Value	Comments
ECCCS	GPMC_ECC_CONFIG	0-3h	Selects the chip-select where ECC is computed
ECC16B	GPMC_ECC_CONFIG	0/1	Selects column number for ECC calculation
ECCCLEAR	GPMC_ECC_CONTROL	0-7h	Clears all ECC result registers
ECCPOINTER	GPMC_ECC_CONTROL	0-7h	A write to this bit field selects the ECC result register where the first ECC computation is stored. Set to 1 by default.
ECCSIZE1	GPMC_ECC_SIZE_CONFIG	0-FFh	Defines ECCSIZE1
ECCSIZE0	GPMC_ECC_SIZE_CONFIG	0-FFh	Defines ECCSIZE0
ECCjRESULTSIZE (j from 1 to 9)	GPMC_ECC_SIZE_CONFIG	0/1	Selects the size of ECCn result register
ECCENABLE	GPMC_ECC_CONFIG	1	Enables the ECC computation

7.1.3.3.12.3.1.3 ECC Computation

The ECC algorithm is a multiple parity bit accumulation computed on the odd and even bit streams extracted from the byte or Word 16 streams. The parity accumulation is split into row and column accumulations, as shown in Figure 7-31 and Figure 7-32. The intermediate row and column parities are used to compute the upper level row and column parities. Only the final computation of each parity bit is used for ECC comparison and correction.

P1o = bit7 XOR bit5 XOR bit3 XOR bit1 on each byte of the data stream

P1e = bit6 XOR bit4 XOR bit2 XOR bit0 on each byte of the data stream

P2o = bit7 XOR bit6 XOR bit3 XOR bit2 on each byte of the data stream

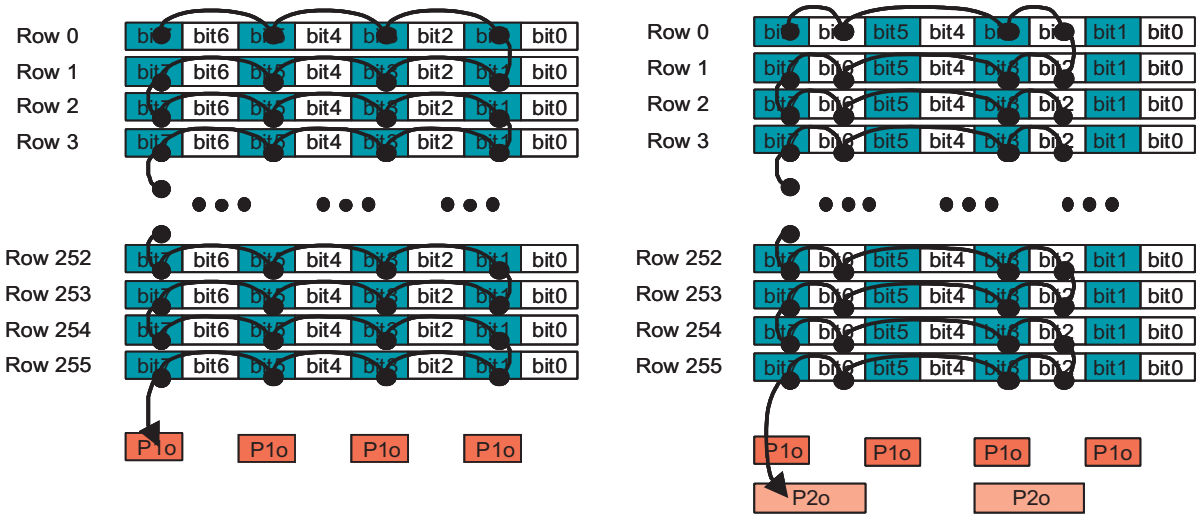
P2e = bit5 XOR bit4 XOR bit1 XOR bit0 on each byte of the data stream

P4o = bit7 XOR bit6 XOR bit5 XOR bit4 on each byte of the data stream

P4e = bit3 XOR bit2 XOR bit1 XOR bit0 on each byte of the data stream

Each column parity bit is XORed with the previous accumulated value.

Figure 7-31. Hamming Code Accumulation Algorithm (1 of 2)



Copyright © 2011, Texas Instruments Incorporated

For line parities, the bits of each new data are XORed together, and line parity bits are computed as:

P8e = row0 XOR row2 XOR row4 XOR ... XOR row254

P8o = row1 XOR row3 XOR row5 XOR ... XOR row255

P16e = row0 XOR row1 XOR row4 XOR row5 XOR ... XOR row252 XOR row 253

P16o = row2 XOR row3 XOR row6 XOR row7 XOR ... XOR row254 XOR row 255

Unused parity bits in the result registers are cleared to 0.

Figure 7-32. Hamming Code Accumulation Algorithm (2 of 2)

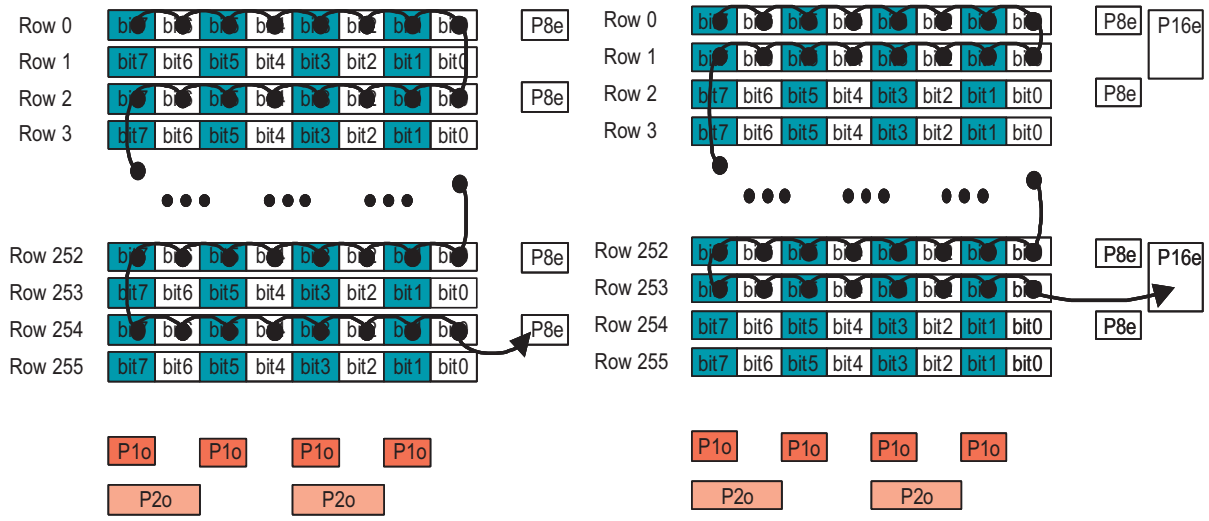


Figure 7-33 shows ECC computation for a 256-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and sixteen row parity bits (P8o-P16o-P32o--P1024o for odd parities, and P8e-P16e-P32e--P1024e for even parities).

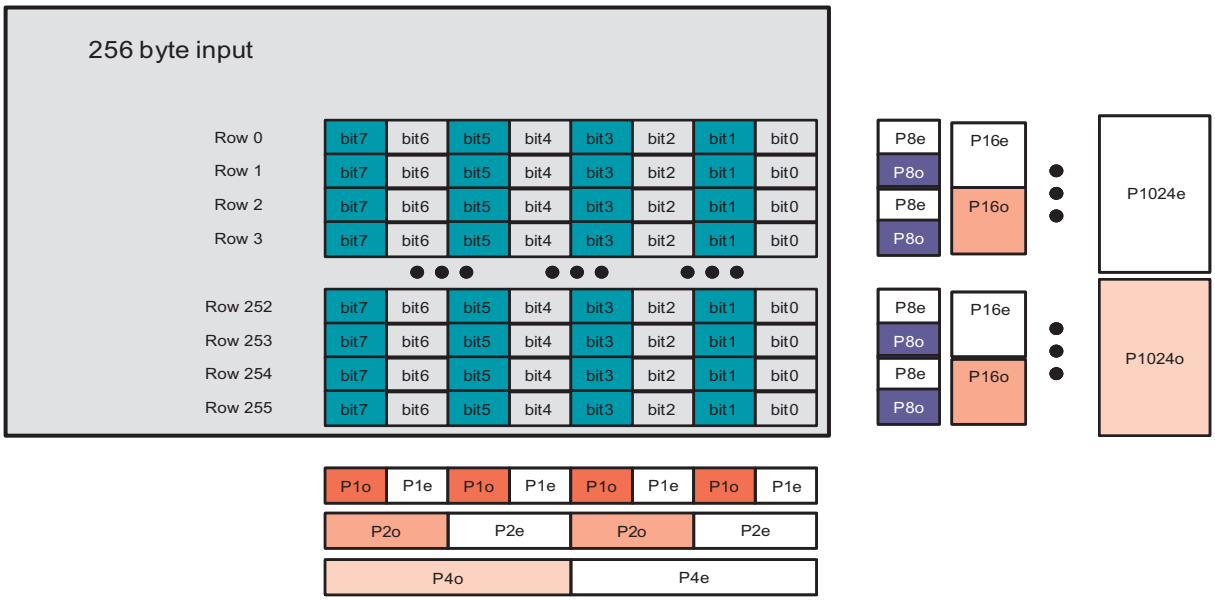
Figure 7-33. ECC Computation for a 256-Byte Data Stream (Read or Write)

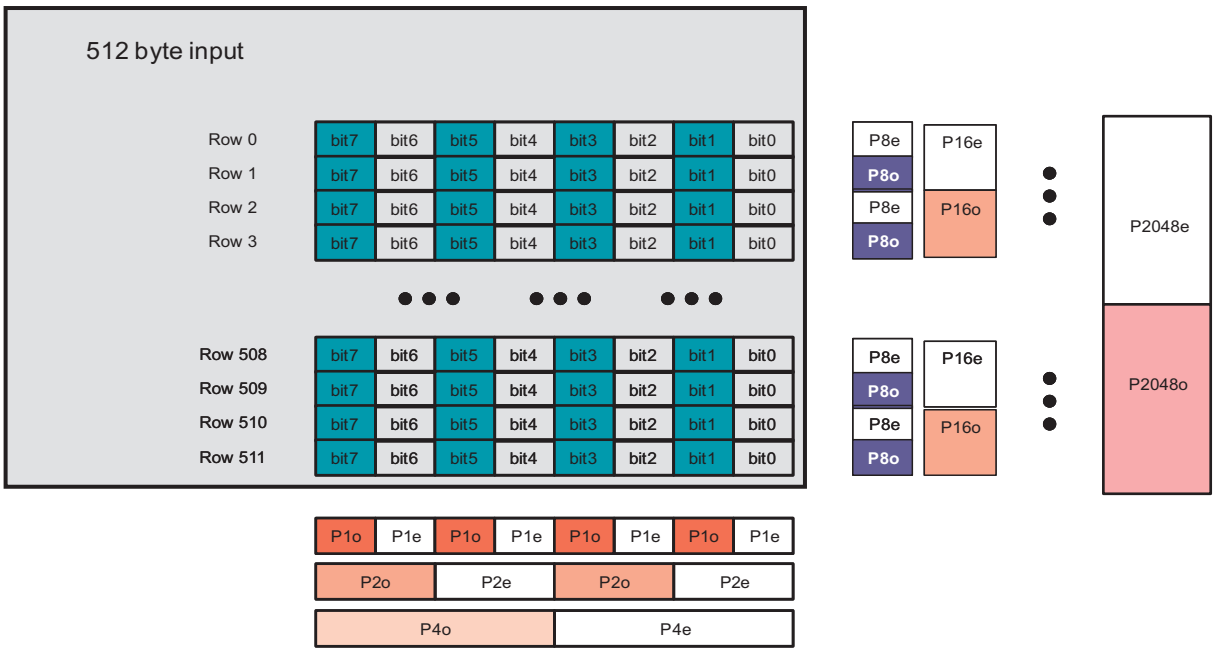


Copyright © 2011, Texas Instruments Incorporated

Figure 7-34 shows ECC computation for a 512-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and eighteen row parity bits (P8o-P16o-P32o--P1024o- - P2048o for odd parities, and P8e-P16e-P32e--P1024e- P2048e for even parities).

For a 2 Kbytes page, four 512 bytes ECC calculations plus one for the spare area are required. Results are stored in the GPMC_ECCj_RESULT registers (j = 1 to 9).

Figure 7-34. ECC Computation for a 512-Byte Data Stream (Read or Write)



7.1.3.3.12.3.1.4 ECC Comparison and Correction

To detect an error, the computed ECC result must be XORed with the parity value stored in the spare area of the accessed page.

- If the result of this logical XOR is all 0s, no error is detected and the read data is correct.
- If every second bit in the parity result is a 1, one bit is corrupted and is located at bit address (P2048o, P1024o, P512o, P256o, P128o, P64o, P32o, P16o, P8o, P4o, P2o, P1o). The software must correct the corresponding bit.
- If only one bit in the parity result is 1, it is an ECC error and the read data is correct.

7.1.3.3.12.3.1.5 ECC Calculation Based on 8-Bit Word

The 8-bit based ECC computation is used for 8-bit wide NAND device interfacing.

The 8-bit based ECC computation can be used for 16-bit wide NAND device interfacing to get backward compatibility on the error-handling strategy used with 8-bit wide NAND devices. In this case, the 16-bit wide data read from or written to the NAND device is fragmented into 2 bytes. According to little-endian access, the least significant bit (LSB) of the 16-bit wide data is ordered first in the byte stream used for 8-bit based ECC computation.

Copyright © 2011, Texas Instruments Incorporated

7.1.3.3.12.3.1.6 ECC Calculation Based on 16-Bit Word

ECC computation based on a 16-bit word is used for 16-bit wide NAND device interfacing. This ECC computation is not supported when interfacing an 8-bit wide NAND device, and the GPMC_ECC_CONFIG[7] ECC16B bit must be cleared to 0 when interfacing an 8-bit wide NAND device.

The parity computation based on 16-bit words affects the row and column parity mapping. The main difference is that the odd and even parity bits P8o and P8e are computed on rows for an 8-bit based ECC while there are computed on columns for a 16-bit based ECC. Figure 7-35 and Figure 7-36.

Figure 7-35. 128 Word16 ECC Computation

7.1.3.3.12.3.2 BCH Code (Bose-Chaudhurl-Hocquenghem)

All references to Error Code Correction (ECC) in this subsection refer to the 4- to 16-bit error correction BCH code.

7.1.3.3.12.3.2.1 Requirements

Read and write accesses to a NAND flash take place by whole pages, in a predetermined sequence: first the data byte page itself, then some spare bytes, including the BCH ECC (and other information). The NAND IC can cache a full page, including spares, for read and write accesses.

Typical page write sequence:

- Sequential write to NAND cache of main data + spare data, for a page. ECC is calculated on the fly. Calculated ECC may be inserted on the fly in the spares, or replaced by dummy accesses.
- When the calculated ECC is replaced by dummy accesses, it must be written to the cache in a second, separate phase. The ECC module is disabled during that time.
- NAND writes its cache line (page) to the array

Typical page read sequence:

- Sequential read of a page. ECC is calculated on the fly.
- ECC module buffers status determines the presence of errors.
- Accesses to several memories may be interleaved by the GPMC, but only one of those memories can be a NAND using the BCH engine at a time; in other words, only one BCH calculation (for example, for a single page) can be on-going at any time. Note also that the sequential nature of NAND accesses guarantees that the data is always written / read out in the same order. BCH-relevant accesses are selected by the GPMCs chip-select.
- Each page may hold up to 4 Kbytes of data, spare bytes not included. This means up to 8 x 512-byte BCH messages. Since all the data is written / read out first, followed by the BCH ECC, this means that the BCH engine must be able to hold 8 104-bit remainders or syndromes (or smaller, 52-bit ones) at the same time.

The BCH module has the capacity to store all remainders internally. After the page start, an internal counter is used to detect the 512-byte sector boundaries. On those boundaries, the current remainder is stored and the divider reset for the next calculation. At the end of the page, the BCH module contains all remainders.

- NAND access cycles hold 8 or 16 bits of data each (1 or 2 bytes); Each NAND cycle takes at least 4 cycles of the GPMCs internal clock. This means the NAND flash timing parameters must define a RDCYCLETIME and a WRCYCLETIME of at least 4 clock cycles after optimization when using the BCH calculator.
- The spare area is assumed to be large enough to hold the BCH ECC, that is, to have at least a message of 13 bytes available per 512-byte sector of data. The zone of unused spare area by the ECC may or may not be protected by the same ECC scheme, by extending the BCH message beyond 512 bytes (maximum codeword is 1023-byte long, ECC included, which leaves a lot of space to cover some spares bytes).

Copyright © 2011, Texas Instruments Incorporated

7.1.3.3.12.3.2.2 Memory-Mapping of the BCH Codeword

BCH encoding considers a block of data to protect as a polynomial message M(x). In our standard case, 512 bytes of data (that is, 2 bits = 4096 bits) are seen as a polynomial of degree 2 - 1 = 4095, with parameters ranging from M0 to M4095. For 512 bytes of data, 52 bits are required for 4-bit error correction, and 104 bits are required for 8-bit error correction and 207 bits are required for 16-bit error correction. The ECC is a remainder polynomial R(x) of degree 103 (or 51, depending on the selected mode). The complete codeword C(x) is the concatenation of M(x) and R(x) as shown in Table 7-13.

Table 7-13. Flattened BCH Codeword Mapping (512 Bytes + 104 Bits)

	Message M(x)	ECC R(x)				
Bit number	M4095	...	M0	R103	...	R0

If the message is extended by the addition of spare bytes to be protected by the same ECC, the principle is still valid. For example, a 3-byte extension of the message gives a polynomial message M(x) of degree ((512 + 3) × 8) - 1 = 4119, for a total of 3 + 13 = 16 spare bytes of spare, all protected as part of the same codeword.

The message and the ECC bits are manipulated and mapped in the GPMC byte-oriented system. The ECC bits are stored in:

- GPMC_BCH_RESULT0_i
- GPMC_BCH_RESULT1_i
- GPMC_BCH_RESULT2_i
- GPMC_BCH_RESULT3_i

7.1.3.3.12.3.2.3 Memory Mapping of the Data Message

The data message mapping shall follow the following rules:

- Bit endianness within a byte is little-endian, that is, the bytes LS bit is also the lowest-degree polynomial parameter: a byte b7-b0 (with b0 the LS bit) represents a segment of polynomial b7 * x + b6 * x + ... + b0 * x
- The message is mapped in the NAND starting with the highest-order parameters, that is, in the lowest addresses of a NAND page.
- Byte endianness within the NANDs 16-bit words is big endian. This means that the same message mapped in 8- and 16-bit memories has the same content at the same byte address.

The BCH module has no visibility over actual addresses. The most important point is the sequence of data word the BCH sees. However, the NAND page is always scanned incrementally in read and write accesses, and this produces the mapping patterns described in the following.

Table 7-14 and Table 7-15 show the mapping of the same 512-byte vector (typically a BCH message) in the NAND memory space. Note that the byte 'address' is only an offset modulo 512 (200h), since the same page may contain several contiguous 512-byte sectors (BCH blocks). The LSB and MSB are respectively the bits M0 and M(2^12-1) of the codeword mapping given above. In both cases the data vectors are aligned, that is, their boundaries coincide with the RAMs data word boundaries.

Table 7-14. Aligned Message Byte Mapping in 8-bit NAND

Byte Offset	8-Bit Word
0	(msb) Byte 511 (1FFh)
1h	Byte 510 (1FEh)
⋮	⋮
1FFh	Byte 0 (0) (LSB)

Table 7-15. Aligned Message Byte Mapping in 16-bit NAND

Byte Offset	16-Bit Words MSB	16-Bit Words LSB
0	Byte 510 (1FEh)	(msb) Byte 511 (1FFh)
2h	Byte 508 (1FCh)	Byte 509 (1FDh)
⋮	⋮	⋮
1FEh	Byte 0 (0)	(lsb) Byte 1 (1)

Table 7-16 and Table 7-17 show the mapping in memory of arbitrarily-sized messages, starting on access (byte or 16-bit word) boundaries for more clarity. Note that message may actually start and stop on arbitrary nibbles. A nibble is a 4-bit entity. The unused nibbles are not discarded, and they can still be used by the BCH module, but as part of the next message section (for example, on another sectors ECC).

Table 7-16. Aligned Nibble Mapping of Message in 8-bit NAND

Byte Offset	8-Bit Word	
	4-Bit Most Significant Nibble	4-Bit Less Significant Nibble
1	(MSB) Nibble S-1	Nibble S-2
2	Nibble S-3	Nibble S-4
⋮	⋮	⋮

(S+3)/2 - 4	Nibble 2	Nibble 1	Nibble 4	Nibble 3
(S+3)/2 - 2			Nibble 0 (LSB)	

Note that many other cases exist than the ones represented above, for example, where the message does not start on a word boundary.

7.1.3.3.12.3.2.4 Memory Mapping of the ECC

The ECC (or remainder) is presented by the BCH module as a single 104-bit (or 52-bit), little-endian vector. It is up to the software to fetch those 13 bytes (or 6 bytes) from the modules interface, then store them to the NANDs spare area (page write) or to an intermediate buffer for comparison with the stored ECC (page read). There are no constraints on the ECC mapping inside the spare area: it is a softwarecontrolled operation.

However, it is advised to maintain a coherence in the respective formats of the message or the ECC remainder once they have been read out of the NAND. The error correction algorithm works from the complete codeword (concatenated message and remainder) once an error as been detected. The creation of this codeword should be made as straightforward as possible.

Copyright © 2011, Texas Instruments Incorporated

There are cases where the same NAND access contains both data and the ECC protecting that data. This is the case when the data/ECC boundary (which can be on any nibble) does not coincide with an access boundary. The ECC is calculated on-the-fly following the write. In that case, the write must also contain part of the ECC because it is impossible to insert the ECC on-the-fly. Instead:

- During the initial page write (BCH encoding), the ECC is replaced by dummy bits. The BCH encoder is by definition turned OFF during the ECC section, so the BCH result is unmodified.
- During a second phase, the ECC is written to the correct location, next to the actual data.
- The completed line buffer is then written to the NAND array.

7.1.3.3.12.3.2.5 Wrapping Modes

For a given wrapping mode, the module automatically goes through a specific number of sections, as data is being fed into the module. For each section, the BCH core can be enabled (in which case the data is fed to the BCH divider) or not (in which case the BCH simply counts to the end of the section). When enabled, the data is added to the ongoing calculation for a given sector number (for example, number 0).

Wrapping modes are described below. To get a better understanding and see the real-life read and write sequences implemented with each mode, see Section 7.1.3.3.12.3.3.

For each mode:

- A sequence describes the mode in pseudo-language, with for each section the size and the buffer used for ECC processing (if ON). The programmable lengths are size, size0 and size1.
- A checksum condition is given. If the checksum condition is not respected for a given mode, the modules behavior is unpredictable. S is the number of sectors in the page; size0 and size1 are the section sizes programmed for the mode, in nibbles.

Note that wrapping modes 8, 9, 10, and 11 insert a 1-nibble padding where the BCH processing is OFF. This is intended for t = 4 ECC, where ECC is 6 bytes long and the ECC area is expected to include (at least) 1 unused nibble to remain byte-aligned.

7.1.3.3.12.3.2.6 Manual Mode (0x0)

This mode is intended for short sequences, added manually to a given buffer through the software data port input. A complete page may be built out of several such sequences.

To process an arbitrary sequence of 4-bit nibbles, accesses to the software data port shall be made, containing the appropriate data. If the sequence end does not coincide with an access boundary (for example, to process 5 nibbles = 20 bits in 16-bit access mode) and those nibbles need to be skipped, a number of unused nibbles shall be programmed in size1 (in the same example: 5 nibbles to process + 3 to discard = 8 nibbles = exactly 2 x 16-bit accesses: we must program size0 = 5, size1 = 3).

Figure 7-37 shows the manual mode sequence and mapping. In this figure, size and size0 are the same parameter.

Figure 7-37. Manual Mode Sequence and Mapping

Section processing sequence:

- One time with buffer
  - size0 nibbles of data, processing ON
  - size1 nibbles of unused data, processing OFF

Checksum: size0 + size1 nibbles must fit in a whole number of accesses.

In the following sections, S is the number of sectors in the page.

7.1.3.3.12.3.2.7 Mode 0x1

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S - (size0 + size1)

7.1.3.3.12.3.2.8 Mode 0xA (10)

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
  - 1 nibble pad spare, processing OFF
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S - (size0 + 1 + size1)

7.1.3.3.12.3.2.9 Mode 0x2

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S - (size0 + size1)

7.1.3.3.12.3.2.10 Mode 0x3

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time with buffer 0
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S - size1)

7.1.3.3.12.3.2.11 Mode 0x7

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time with buffer 0
  - size0 nibbles spare, processing ON
- Repeat S times (no buffer used)
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = size0 + (S - size1)

7.1.3.3.12.3.2.12 Mode 0x8

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time with buffer 0
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - 1 nibble padding spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S - (1+size1))

7.1.3.3.12.3.2.13 Mode 0x4

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time (no buffer used)
  - size0 nibbles spare, processing OFF
- Repeat with buffer 0 to S-1
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S - size1)

7.1.3.3.12.3.2.14 Mode 0x9

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time (no buffer used)
  - size0 nibbles spare, processing OFF
- Repeat with buffer 0 to S-1
  - 1 nibble padding spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S - (1+size1))

7.1.3.3.12.3.3 Supported NAND Page Mappings and ECC Schemes

The following rules apply throughout the entire mapping description:

- Main data area (sectors) size is hardcoded to 512 bytes.
- Spare area size is programmable.
- All page sections (of main area data bytes, protected spare bytes, unprotected spare bytes, and ECC) are defined as explained in Section 7.1.3.3.12.3.2.3.

Each one of the following sections shows a NAND page mapping example (per-sector spare mappings, pooled spare mapping, per-sector spare mapping, with ECC separated at the end of the page).

In the mapping diagrams, sections that belong to the same BCH codeword have the same color (blue or green); unprotected sections are not covered (orange) by the BCH scheme.

Below each mapping diagram, a write (encoding) and read (decoding: syndrome generation) sequence is given, with the number of the active buffers at each point in time (yellow). In the inactive zones (grey), no computing is taking place but the data counter is still active.

In Figure 7-38 to Figure 7-40, tables on the left summarize the mode, size0, size1 parameters to program for respectively write and read processing of a page, with the given mapping, where:

- P is the size of spare byte section Protected by the ECC (in nibbles)
- U is the size of spare byte section Unprotected by the ECC (in nibbles)
- E is the size of the ECC itself (in nibbles)
- S is the number of Sectors per page (2 in the current diagrams)

Each time the processing of a BCH block is complete (ECC calculation for write/encoding, syndrome generation for read/decoding, indicated by red arrows), the update pointer is pulsed. Note that the processing for block 0 can be the first or the last to complete, depending on the NAND page mapping and operation (read or write). All examples show a page size of 1kByte + spares, that is, S = 2 sectors of 512 bytes. The same principles can be extended to larger pages by adding more sectors.

The actual BCH codeword size is used during the error location work to restrict the search range: by definition, errors can only happen in the codeword that was actually written to the NAND, and not in the mathematical codeword of n = 2 - 1 = 8191 bits. That codeword (higher-order bits) is all-zero and implicit during computations.

The actual BCH codeword size depends on the mode, on the programmed sizes and on the sector number (all sizes in nibbles):

- Spares mapped and protected per sector (Figure 7-38: see M1-M2-M3-M9-M10):
  - all sectors: (512) + P + E
- Spares pooled and protected by sector 0 (Figure 7-38: see M5-M6):
  - sector 0 codeword: (512) + P + E
  - other sectors: (512) + E
- Unprotected spares (Figure 7-38: see M4-M7-M8-M11-M12):
  - all codewords (512) + E

7.1.3.3.12.3.3.1 Per-Sector Spare Mappings

In these schemes (Figure 7-38), each 512-byte sector of the main area has its own dedicated section of the spare area. The spare area of each sector is composed of:

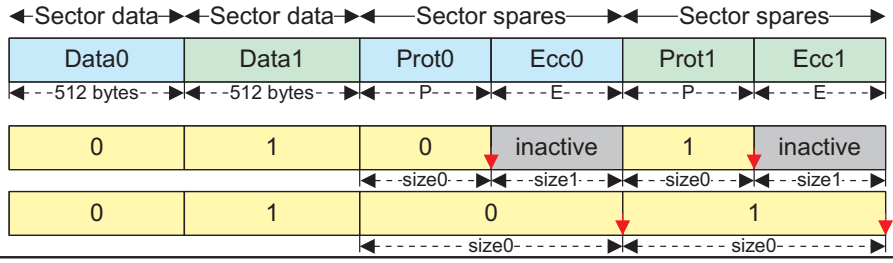
- ECC, which must be located after the data it protects
- other data, which may or may not be protected by the sectors ECC

Figure 7-38. NAND Page Mapping and ECC: Per-Sector Schemes

M1

Per-sector spares
Spares covered by sector ECC per sector ECC mapping.

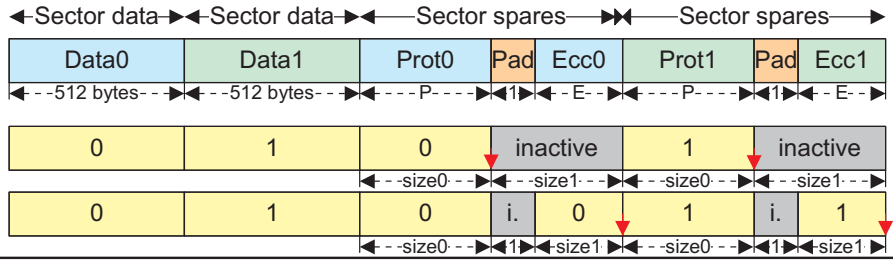
	Mode	Size0	Size1
Write	1	P	E
Read	1	P+E	0



M2

Per-sector spares
Spares covered by sector ECC per sector, left-padded ECC.

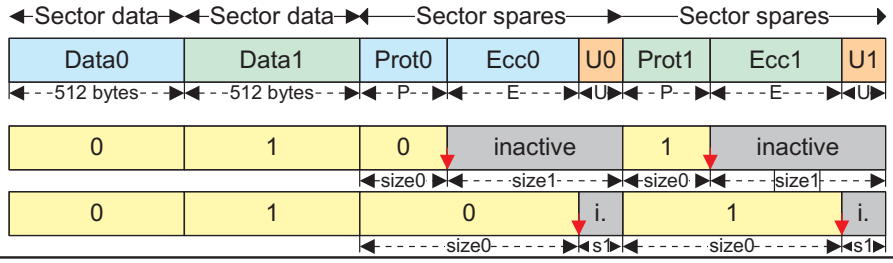
	Mode	Size0	Size1
Write	1	P	1+E
Read	10	P	E



M3

Per-sector spares
Spares covered by sector ECC, ECC not right-aligned.

	Mode	Size0	Size1
Write	1	P	E+U
Read	1	P+E	U



M4

Per-sector spares
Spares not covered by ECC, ECC right-aligned per sector.

	Mode	Size0	Size1
Write	2	U+E	0
Read	2	U	E

7.1.3.3.12.3.3.2 Pooled Spare Mapping

In these schemes (Figure 7-39), the spare area is pooled for the page.

- The ECC of each sector is aligned at the end of the spare area.
- The non-ECC spare data may or may not be covered by the ECC of sector 0

Figure 7-39. NAND Page Mapping and ECC: Pooled Spare Schemes

7.1.3.3.12.4 Prefetch and Write-Posting Engine

NAND device data access cycles are usually much slower than the MPU system frequency; such NAND read or write accesses issued by the processor will impact the overall system performance, especially considering long read or write sequences required for NAND page loading or programming. To minimize this effect on system performance, the GPMC includes a prefetch and write-posting engine, which can be used to read from or write to any chip-select location in a buffered manner.

The prefetch and write-posting engine is a simplified embedded-access requester that presents requests to the access engine on a user-defined chip-select target. The access engine interleaves these requests with any request coming from the L3 interface; as a default the prefetch and write-posting engine has the lowest priority.

The prefetch and write-posting engine is dedicated to data-stream access (as opposed to random data access); thus, it is primarily dedicated to NAND support. The engine does not include an address generator; the request is limited to chip-select target identification. It includes a 64-byte FIFO associated with a DMA request synchronization line, for optimal DMA-based use.

The prefetch and write-posting engine uses an embedded 64 bytes (32 16-bit word) FIFO to prefetch data from the NAND device in read mode (prefetch mode) or to store host data to be programmed into the NAND device in write mode (write-posting mode). The FIFO draining and filling (read and write) can be controlled either by the MPU through interrupt synchronization (an interrupt is triggered whenever a programmable threshold is reached) or the sDMA through DMA request synchronization, with a programmable request byte size in both prefetch or posting mode.

The prefetch and write-posting engine includes a single memory pool. Therefore, only one mode, read or write, can be used at any given time. In other words, the prefetch and write-posting engine is a single-context engine that can be allocated to only one chip-select at a time for a read prefetch or a write-posting process.

The engine does not support atomic command and address phase programming and is limited to linear memory read or write access. In consequence, it is limited to NAND data-stream access. The engine relies on the MPU NAND software driver to control block and page opening with the correct data address pointer initialization, before the engine can read from or write to the NAND memory device.

Once started, the engine data reads and writes sequencing is solely based on FIFO location availability and until the total programmed number of bytes is read or written.

Any host-concurrent accesses to a different chip-select are correctly interleaved with ongoing engine accesses. The engine has the lowest priority access so that host accesses to a different chip-select do not suffer a large latency.

A round-robin arbitration scheme can be enabled to ensure minimum bandwidth to the prefetch and write-posting engine in the case of back-to-back direct memory requests to a different chip-select. If the GPMC_PREFETCH_CONFIG1[23] PFPWENROUNDROBIN bit is enabled, the arbitration grants the prefetch and write posting engine access to the GPMC bus for a number of requests programmed in the GPMC_PREFETCH_CONFIG1[19-16] PFPWWEIGHTEDPRIO field.

The prefetch/write-posting engine read or write request is routed to the access engine with the chip-select destination ID. After the required arbitration phase, the access engine processes the request as a single access with the data access size equal to the device size specified in the corresponding chip-select configuration.

The destination chip-select configuration must be set to the NAND protocol-compatible configuration for which address lines are not used (the address bus is not changed from its current value). Selecting a different chip-select configuration can produce undefined behavior.

7.1.3.3.12.4.1 General Facts About the Engine Configuration

The engine can be configured only if the GPMC_PREFETCH_CONTROL[0] STARTENGINE bit is de-asserted.

The engine must be correctly configured in prefetch or write-posting mode and must be linked to a NAND chip-select before it can be started. The chip-select is linked using the GPMC_PREFETCH_CONFIG1[26-24] ENGINECSSELECTOR field.

In both prefetch and write-posting modes, the engine respectivelly uses byte or 16-bit word access requests for an 8- or 16-bit wide NAND device attached to the linked chip-select. The FIFOTHRESHOLD and TRANSFERCOUNT fields must be programmed accordingly as a number of bytes or a number of 16-bit word.

When the GPMC_PREFETCH_CONFIG1[7] ENABLEENGINE bit is set, the FIFO entry on the L3 interconnect port side is accessible at any address in the associated chip-select memory region. When the ENABLEENGINE bit is set, any host access to this chip-select is rerouted to the FIFO input. Directly accessing the NAND device linked to this chip-select from the host is still possible through these registers:

- GPMC_NAND_COMMAND_i
- GPMC_NAND_ADDRESS_i
- GPMC_NAND_DATA_i

The FIFO entry on the L3 interconnect port can be accessed with Byte, 16-bit word, or 32-bit word access size, according to little-endian format, even though the FIFO input is 32-bit wide.

The FIFO control is made easier through the use of interrupts or DMA requests associated with the FIFOTHRESHOLD bit field. The GPMC_PREFETCH_STATUS[30-24] FIFOPOINTER field monitors the number of available bytes to be read in prefetch mode or the number of free empty slots which can be written in write-posting mode. The GPMC_PREFETCH_STATUS[13-0] COUNTVALUE field monitors the number of remaining bytes to be read or written by the engine according to the TRANSFERCOUNT value. The FIFOPOINTER and COUNTVALUE bit fields are always expressed as a number of bytes even if a 16-bit wide NAND device is attached to the linked chip-select.

In prefetch mode, when the FIFOPOINTER equals 0, that is, the FIFO is empty, a host read access receives the byte last read from the FIFO as its response. In case of 32-bit word or 16-bit word read accesses, the last byte read from the FIFO is copied the required number of times to fit the requested word size. In write-posting mode, when the FIFOPOINTER equals 0, that is, the FIFO is full, a host write overwrites the last FIFO byte location. There is no underflow or overflow error reporting in the GPMC.

Copyright © 2011, Texas Instruments Incorporated

7.1.3.3.12.4.2 Prefetch Mode

The prefetch mode is selected when the GPMC_PREFETCH_CONFIG1[0] ACCESSMODE bit is cleared.

The MPU NAND software driver must issue the block and page opening (READ) command with the correct data address pointer initialization before the engine can be started to read from the NAND memory device. The engine is started by asserting the GPMC_PREFETCH_CONTROL[0] STARTENGINE bit. The STARTENGINE bit automatically clears when the prefetch process completes.

If required, the ECC calculator engine must be initialized (i.e., reset, configured, and enabled) before the prefetch engine is started, so that the ECC is correctly computed on all data read by the prefetch engine.

When the GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE bit is cleared, the prefetch engine starts requesting data as soon as the STARTENGINE bit is set. If using this configuration, the host must monitor the NAND device-ready pin so that it only sets the STARTENGINE bit when the NAND device is in a ready state, meaning data is valid for prefetching.

When the SYNCHROMODE bit is set, the prefetch engine starts requesting data when an active to inactive wait signal transition is detected. The transition detector must be cleared before any transition detection; see Section 7.1.3.3.12.2.2. The GPMC_PREFETCH_CONFIG1[5-4] WAITPINSELECTOR field selects which gpmc_wait pin edge detector triggers the prefetch engine in this synchronized mode.

If the STARTENGINE bit is set after the NAND address phase (page opening command), the engine is effectively started only after the actual NAND address phase completion. To prevent GPMC stall during this NAND address phase, set the STARTENGINE bit field before NAND address phase completion when in synchronized mode. The prefetch engine will start when an active to inactive wait signal transition is detected. The STARTENGINE bit is automatically cleared on prefetch process completion.

The prefetch engine issues a read request to fill the FIFO with the amount of data specified by GPMC_PREFETCH_CONFIG2[13-0] TRANSFERCOUNT field.

Table 7-22 describes the prefetch mode configuration.

Table 7-22. Prefetch Mode Configuration

Bit Field	Register	Value	Comments
STARTENGINE	GPMC_PREFETCH_CONTROL	0	Prefetch engine can be configured only if STARTENGINE is cleared to 0.
ENGINECSSELECTOR	GPMC_PREFETCH_CONFIG1	0 to 3h	Selects the chip-select associated with a NAND device where the prefetch engine is active.
ACCESSMODE	GPMC_PREFETCH_CONFIG1	0	Selects prefetch mode
FIFOTHRESHOLD	GPMC_PREFETCH_CONFIG1		Selects the maximum number of bytes read or written by the host on DMA or interrupt request
TRANSFERCOUNT	GPMC_PREFETCH_CONFIG1		Selects the number of bytes to be read or written by the engine to the selected chip-select
SYNCHROMODE	GPMC_PREFETCH_CONFIG1	0/1	Selects when the engine starts the access to the chip-select
WAITPINSELECT	GPMC_PREFETCH_CONFIG1	0 to 1	Selects wait pin edge detector (if GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE = 1)
ENABLEOPTIMIZEDACCESS	GPMC_PREFETCH_CONFIG1	0/1	See Section 7.1.3.3.12.4.6
CYCLEOPTIMIZATION	GPMC_PREFETCH_CONFIG1		Number of clock cycle removed to timing parameters
ENABLEENGINE	GPMC_PREFETCH_CONFIG1	1	Engine enabled
STARTENGINE	GPMC_PREFETCH_CONFIG1	1	Starts the prefetch engine

7.1.3.3.12.4.3 FIFO Control in Prefetch Mode

The FIFO can be drained directly by the MPU or by an eDMA channel.

In MPU draining mode, the FIFO status can be monitored through the GPMC_PREFETCH_STATUS[30-24] FIFOPOINTER field or through the GPMC_PREFETCH_STATUS[16] FIFOTHRESHOLDSTATUS bit. The FIFOPOINTER indicates the current number of available data to be read; FIFOTHRESHOLDSTATUS set to 1 indicates that at least FIFOTHRESHOLD bytes are available from the FIFO.

An interrupt can be triggered by the GPMC if the GPMC_IRQENABLE[0] FIFOEVENTENABLE bit is set. The FIFO interrupt event is logged, and the GPMC_IRQSTATUS[0] FIFOEVENTSTATUS bit is set. To clear the interrupt, the MPU must read all the available bytes, or at least enough bytes to get below the programmed FIFO threshold, and the FIFOEVENTSTATUS bit must be cleared to enable further interrupt events. The FIFOEVENTSTATUS bit must always be reset prior to asserting the FIFOEVENTENABLE bit to clear any out-of-date logged interrupt event. This interrupt generation must be enabled after enabling the STARTENGINE bit.

Prefetch completion can be monitored through the GPMC_PREFETCH_STATUS[13-0] COUNTVALUE field. COUNTVALUE indicates the number of currently remaining data to be requested according to the TRANSFERCOUNT value. An interrupt can be triggered by the GPMC when the prefetch process is complete (that is, COUNTVALUE equals 0) if the GPMC_IRQENABLE[1] TERMINALCOUNTEVENTENABLE bit is set. At prefetch completion, the TERMINALCOUNT interrupt event is also logged, and the GPMC_IRQSTATUS[1] TERMINALCOUNTSTATUS bit is set. To clear the interrupt, the MPU must clear the TERMINALCOUNTSTATUS bit. The TERMINALCOUNTSTATUS bit must always be cleared prior to asserting the TERMINALCOUNTEVENTENABLE bit to clear any out-of-date logged interrupt event.

NOTE: The COUNTVALUE value is only valid when the prefetch engine is active (started), and an interrupt is only triggered when COUNTVALUE reaches 0, that is, when the prefetch engine automatically goes from an active to an inactive state.

The number of bytes to be prefetched (programmed in TRANSFERCOUNT) must be a multiple of the programmed FIFOTHRESHOLD to trigger the correct number of interrupts allowing a deterministic and transparent FIFO control. If this guideline is respected, the number of ISR accesses is always required and the FIFO is always empty after the last interrupt is trigerred. In other cases, the TERMINALCOUNT interrupt must be used to read the remaining bytes in the FIFO (the number of remaining bytes being lower than the FIFOTHRESHOLD value).

In DMA draining mode, the GPMC_PREFETCH_CONFIG1[2] DMAMODE bit must be set so that the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes are ready to be read from the FIFO. The DMA channel owning this DMA request must be programmed so that the number of bytes programmed in FIFOTHRESHOLD is read from the FIFO during the DMA request process. The DMA request is kept active until this number of bytes has effectively been read from the FIFO, and no other DMA request can be issued until the ongoing active request is complete.

In prefetch mode, the TERMINALCOUNT event is also a source of DMA requests if the number of bytes to be prefetched is not a multiple of FIFOTHRESHOLD, the remaining bytes in the FIFO can be read by the DMA channel using the last DMA request. This assumes that the number of remaining bytes to be read is known and controlled through the DMA channel programming model.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive to active prefetch (the STARTENGINE bit is set to 1). The associated DMA channel must always be enabled by the MPU after setting the STARTENGINE bit so that the out-of-date active DMA request does not trigger spurious DMA transfers.

Copyright © 2011, Texas Instruments Incorporated

7.1.3.3.12.4.4 Write-Posting Mode

The write-posting mode is selected when the GPMC_PREFETCH_CONFIG1[0] ACCESSMODE bit is set.

The MPU NAND software driver must issue the correct address pointer initialization command (page program) before the engine can start writing data into the NAND memory device. The engine starts when the GPMC_PREFETCH_CONTROL[0] STARTENGINE bit is set to 1. The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the MPU NAND software driver must issue the second cycle program command and monitor the status for programming process completion (adding ECC handling, if required).

If used, the ECC calculator engine must be started (configured, reset, and enabled) before the posting engine is started so that the ECC parities are properly calculated on all data written by the prefetch engine to the associated chip-select.

In write-posting mode, the GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE bit must be cleared so that posting starts as soon as the STARTENGINE bit is set and the FIFO is not empty.

If the STARTENGINE bit is set after the NAND address phase (page program command), the STARTENGINE setting is effective only after the actual NAND command completion. To prevent GPMC stall during this NAND command phase, set the STARTENGINE bit field before the NAND address completion and ensure that the associated DMA channel is enabled after the NAND address phase.

The posting engine issues a write request when valid data are available from the FIFO and until the programmed GPMC_PREFETCH_CONFIG2[13-0] TRANSFERCOUNT accesses have been completed.

The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the MPU NAND software driver must issue the second cycle program command and monitor the status for programming process completion. The closing program command phase must only be issued when the full NAND page has been written into the NAND flash write buffer, including the spare area data and the ECC parities, if used.

Table 7-23. Write-Posting Mode Configuration

Bit Field	Register	Value	Comments
STARTENGINE	GPMC_PREFETCH_CONTROL	0	Write-posting engine can be configured only if STARTENGINE is cleared to 0.
ENGINECSSELECTOR	GPMC_PREFETCH_CONFIG1	0 to 3h	Selects the chip-select associated with a NAND device where the prefetch engine is active
ACCESSMODE	GPMC_PREFETCH_CONFIG1	1	Selects write-posting mode
FIFOTHRESHOLD	GPMC_PREFETCH_CONFIG1		Selects the maximum number of bytes read or written by the host on DMA or interrupt request
TRANSFERCOUNT	GPMC_PREFETCH_CONFIG2		Selects the number of bytes to be read or written by the engine from/to the selected chip-select
SYNCHROMODE	GPMC_PREFETCH_CONFIG1	0	Engine starts the access to chip-select as soon as STARTENGINE is set.
ENABLEOPTIMIZEDACCESS	GPMC_PREFETCH_CONFIG1	0/1	See Section 7.1.3.3.12.4.6
CYCLEOPTIMIZATION	GPMC_PREFETCH_CONFIG		
ENABLEENGINE	GPMC_PREFETCH_CONFIG1	1	Engine enabled
STARTENGINE	GPMC_PREFETCH_CONTROL	1	Starts the prefetch engine

7.1.3.3.12.4.5 FIFO Control in Write-Posting Mode

The FIFO can be filled directly by the MPU or by an sDMA channel.

In MPU filling mode, the FIFO status can be monitored through the FIFOPOINTER or through the GPMC_PREFETCH_STATUS[16] FIFOTHRESHOLDSTATUS bit. FIFOPOINTER indicates the current number of available free byte places in the FIFO, and the FIFOTHRESHOLDSTATUS bit, when set, indicates that at least FIFOTHRESHOLD free byte places are available in the FIFO.

An interrupt can be issued by the GPMC if the GPMC_IRQENABLE[0] FIFOEVENTENABLE bit is set. When the interrupt is fired, the GPMC_IRQSTATUS[0] FIFOEVENTSTATUS bit is set. To clear the interrupt, the MPU must write enough bytes to fill the FIFO, or enough bytes to get below the programmed threshold, and the FIFOEVENTSTATUS bit must be cleared to get further interrupt events. The FIFOEVENTSTATUS bit must always be cleared prior to asserting the FIFOEVENTENABLE bit to clear any out-of-date logged interrupt event. This interrupt must be enabled after enabling the STARTENGINE bit

The posting completion can be monitored through the GPMC_PREFETCH_STATUS[13-0] COUNTVALUE field. COUNTVALUE indicates the current number of remaining data to be written based on the TRANSFERCOUNT value. An interrupt is issued by the GPMC when the write-posting process completes (that is, COUNTVALUE equal to 0) if the GPMC_IRQENABLE[1] TERMINALCOUNTEVENTENABLE bit is set. When the interrupt is fired, the GPMC_IRQSTATUS[1] TERMINALCOUNTSTATUS bit is set. To clear the interrupt, the MPU must clear the TERMINALCOUNTSTATUS bit. The TERMINALCOUNTSTATUS bit must always be cleared prior to asserting the TERMINALCOUNTEVENTENABLE bit to clear any out-of-date logged interrupt event.

NOTE: The COUNTVALUE value is only valid if the write-posting engine is active and started, and an interrupt is only issued when COUNTVALUE reaches 0, that is, when the posting engine automatically goes from active to inactive.

In DMA filling mode, the DMAMode bit field in the GPMC_PREFETCH_CONFIG1[2] DMAMODE bit must be set so that the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes-free places are available in the FIFO. The DMA channel owning this DMA request must be programmed so that a number of bytes equal to the value programmed in the FIFOTHRESHOLD bit field are written into the FIFO during the DMA access. The DMA request remains active until the associated number of bytes has effectively been written into the FIFO, and no other DMA request can be issued until the ongoing active request has been completed.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive to active prefetch (STARTENGINE set to 1). The associated DMA channel must always be enabled by the MPU after setting the STARTENGINE bit so that an out-of-date active DMA request does not trigger spurious DMA transfers.

In write-posting mode, the DMA or the MPU fill the FIFO with no consideration to the associated byte enables. Any byte stored in the FIFO is written into the memory device.

7.1.3.3.12.4.6 Optimizing NAND Access Using the Prefetch and Write-Posting Engine

Access time to a NAND memory device can be optimized for back-to-back accesses if the associated CSn signal is not deasserted between accesses. The GPMC access engine can track prefetch engine accesses to optimize the access timing parameter programmed for the allocated chip-select, if no accesses to other chip-selects (that is, interleaved accesses) occur. Similarly, the access engine also eliminates the CYCLE2CYCLEDELAY even if CYCLE2CYCLESAMECSEN is set. This capability is limited to the prefetch and write-posting engine accesses, and MPU accesses to a NAND memory device (through the defined chip-select memory region or through the GPMC_NAND_DATA_i are never optimized.

The GPMC_PREFETCH_CONFIG1[27] ENABLEOPTIMIZEDACCESS bit must be set to enable optimized accesses. To optimize access time, the GPMC_PREFETCH_CONFIG1[30-28] CYCLEOPTIMIZATION field defines the number of GPMC_FCLK cycles to be suppressed from the RDCYCLETIME, WRCYCLETIME, RDACCESSTIME, WRACCESSTIME, CSOFFTIME, ADVOFFTIME, OEOFFTIME, and WEOFFTIME timing parameters.

Figure 7-41, in the case of back-to-back accesses to the NAND flash through the prefetch engine, CYCLE2CYCLESAMECSEN is forced to 0 when using optimized accesses. The first access uses the regular timing settings for this chip-select. All accesses after this one use settings reduced by x clock cycles, x being defined by the GPMC_PREFETCH_CONFIG1[30-28] CYCLEOPTIMIZATION field.

Figure 7-41. NAND Read Cycle Optimization Timing Description

7.1.3.3.12.4.7 Interleaved Accesses Between Prefetch and Write-Posting Engine and Other Chip-Selects

Any on-going read or write access from the prefetch and write-posting engine is completed before an access to any other chip-select can be initiated. As a default, the arbiter uses a fixed-priority algorithm, and the prefetch and write-posting engine has the lowest priority. The maximum latency added to access starting time in this case equals the RDCYCLETIME or WRCYCLETIME (optimized or not) plus the requested BUSTURNAROUND delay for bus turnaround completion programmed for the chip-select to which the NAND device is connected to.

Alternatively, a round-robin arbitration can be used to prioritize accesses to the external bus. This arbitration scheme is enabled by setting the GPMC_PREFETCH_CONFIG1[23] PFPWENROUNDROBIN bit. When a request to another chip-select is received while the prefetch and write-posting engine is active, priority is given to the new request. The request processed thereafter is the prefetch and write-posting engine request, even if another interconnect request is passed in the mean time. The engine keeps control of the bus for an additional number of requests programmed in the GPMC_PREFETCH_CONFIG1[19-16] PFPWWEIGHTEDPRIO bit field. Control is then passed to the direct interconnect request.

As an example, the round-robin arbitration scheme is selected with PFPWWEIGHTEDPRIO set to 2h. Considering the prefetch and write-posting engine and the interconnect interface are always requesting access to the external interface, the GPMC grants priority to the direct interconnect access for one request. The GPMC then grants priority to the engine for three requests, and finnaly back to the direct interconnect access, until the arbiter is reset when one of the two initiators stops initiating requests.

7.1.3.4 GPMC High-Level Programming Model Overview

The high-level programming model introduces a top-down approach for users that need to configure the GPMC module. Figure 7-42 shows a programming model top-level diagram for the GPMC. Each block of the diagram is described in one of the following subsections through a set of registers to configure. Table 7-24 and Table 7-25 list each step in the model.

7.1.3.9.1 GPMC Timing Parameters Formulas

This section intends to help the user to calculate the GPMC timing bit fields values. Formulas are not listed exhaustively.

The section details:

- NAND Flash Interface Timing Parameters Formulas
- Synchronous NOR Flash Timing Parameters Formulas
- Asynchronous NOR Flash Timing Parameters Formulas

7.1.3.9.1.1 NAND Flash Interface Timing Parameters Formulas

This section lists formulas to use in order to calculate NAND timing parameters. This is the case when GPMC_CONFIG1_i[11-10] DEVICETYPE = 2h. Table 7-42 details NAND timing parameters.

Table 7-42. NAND Formulas Description Table

Configuration Parameter	Unit	Description
A	ns	Pulse duration - GPMC_WEn valid time
B	ns	Delay time - GPMC_CSn valid to GPMC_WEn valid
C	ns	Delay time - GPMC_BE0n_CLE/GPMC_ADVn_ALE high to GPMC_WEn valid
D	ns	Delay time - GPMC_AD[15:0] valid to GPMC_WEn valid
E	ns	Delay time - GPMC_WEn invalid to GPMC_AD[15:0] invalid
F	ns	Delay time - GPMC_WEn invalid to GPMC_BE0n_CLE/GPMC_ADVn_ALE invalid
G	ns	Delay time - GPMC_WEn invalid to GPMC_CSn invalid
H	ns	Cycle time - Write cycle time
I	ns	Delay time - GPMC_CSn valid to GPMC_OEn valid
J	ns	Setup time - GPMC_AD[15:0] valid to GPMC_OEn invalid
K	ns	Pulse duration - GPMC_OEn valid time
L	ns	Cycle time - Read cycle time
M	ns	Delay time - GPMC_OEn invalid to GPMC_CSn invalid

The configuration parameters are calculated through the following formulas.

A = (WEOffTime - WEOnTime) * (TimeParaGranularity + 1) * GPMC_FCLK period

B = ((WEOnTime - CSOnTime) * (TimeParaGranularity + 1) + 0.5 * (WEExtraDelay - CSExtraDelay)) * GPMC_FCLK period

C = ((WEOnTime - ADVOnTime) * (TimeParaGranularity + 1) + 0.5 * (WEExtraDelay - ADVExtraDelay)) * GPMC_FCLK period

D = (WEOnTime * (TimeParaGranularity + 1) + 0.5 * WEExtraDelay) * GPMC_FCLK period

E = (WrCycleTime - WEOffTime * (TimeParaGranularity + 1) - 0.5 * WEExtraDelay) * GPMC_FCLK period

F = (ADVWrOffTime - WEOffTime * (TimeParaGranularity + 1) + 0.5 * (ADVExtraDelay - WEExtraDelay) * GPMC_FCLK period

G = (CSWrOffTime - WEOffTime * (TimeParaGranularity + 1) + 0.5 * (CSExtraDelay - WEExtraDelay) * GPMC_FCLK period

H = WrCycleTime * (1 + TimeParaGranularity) * GPMC_FCLK period

I = ((OEOnTime - CSOnTime) * (TimeParaGranularity + 1) + 0.5 * (OEExtraDelay - CSExtraDelay)) * GPMC_FCLK period

J = ((AccessTime - OEOffTime) * (TimeParaGranularity + 1) - 0.5 * OEExtraDelay)) * GPMC_FCLK period

Copyright © 2011, Texas Instruments Incorporated

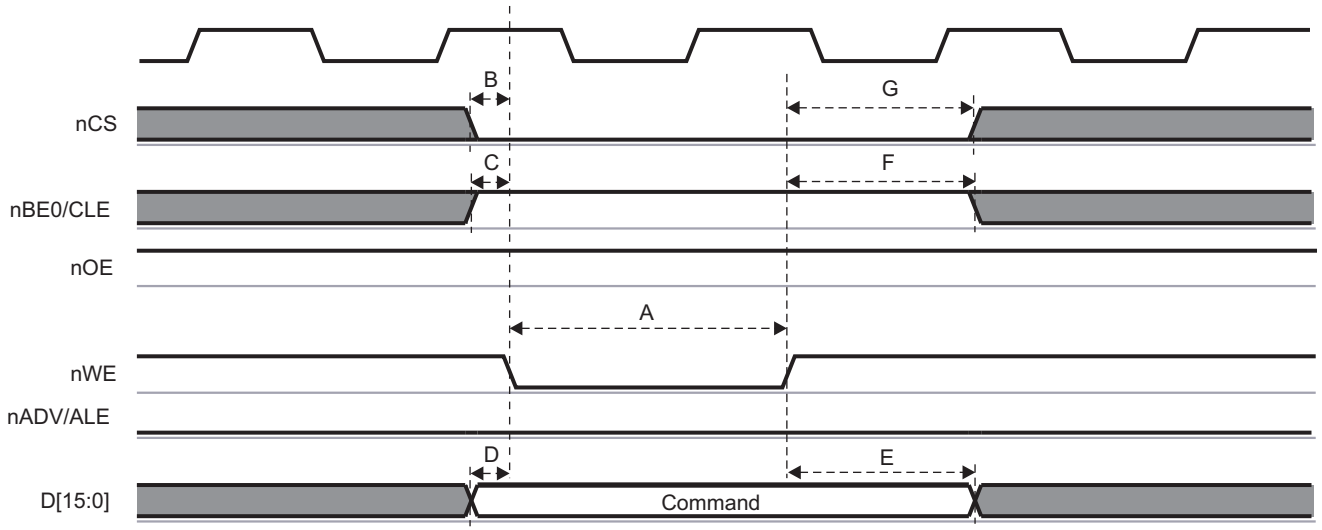
K = (OEOffTime - OEOnTime) * (1 + TimeParaGranularity) * GPMC_FCLK period

L = RdCycleTime * (1 + TimeParaGranularity) * GPMC_FCLK period

M = (CSRdOffTime - OEOffTime * (TimeParaGranularity + 1) + 0.5 * (CSExtraDelay - OEExtraDelay) * GPMC_FCLK period

Figure 7-44 shows a command latch cycle timing simplified example where formulas are associated with signal waves.

Figure 7-44. NAND Command Latch Cycle Timing Simplified Example



7.1.3.9.1.2 *Synchronous NOR Flash Timing Parameters Formulas*

This section lists all formulas to use in order to calculate synchronous NOR timing parameters. This is the case when GPMC_CONFIG1_i[11-10] DEVICETYPE = 0 and when READTYPE or WRITETYPE are set to synchronous mode.

Table 7-43. Synchronous NOR Formulas Description Table

Configuration Parameter	Unit	Description
A	ns	Pulse duration - GPMC_CSn low
B	ns	Delay time - address bus valid to GPMC_CLK first edge
		Delay time - GPMC_BE0n_CLE/GPMC_BE1n valid to GPMC_CLK first edge
C	ns	Pulse duration - GPMC_BE0n_CLE/GPMC_BE1n low
D	ns	Delay time - GPMC_CLK rising edge to GPMC_BE0n_CLE/GPMC_BE1n invalid
		Delay time - GPMC_CLK rising edge to GPMC_ADVn_ALE invalid
E	ns	Delay time - GPMC_CLK rising edge to GPMC_CSn invalid
		Delay time - GPMC_CLK rising edge to GPMC_OEn invalid
F	ns	Delay time - GPMC_CLK rising edge to GPMC_CSn transition
G	ns	Delay time - GPMC_CLK rising edge to GPMC_ADVn_ALE transition
H	ns	Delay time - GPMC_CLK rising edge to GPMC_OEn transition
I	ns	Delay time - GPMC_CLK rising edge to GPMC_WEn transition
J	ns	Delay time - GPMC_CLK rising edge to GPMC_AD data bus transition
		Delay time - GPMC_CLK rising edge to GPMC_BE0n_CLE/GPMC_BE1n transition
K	ns	Pulse duration - GPMC_ADVn_ALE low
L	ns	Delay time - GPMC_WAIT invalid to first data latching GPMC_CLK edge

Copyright © 2011, Texas Instruments Incorporated

The configuration parameters are calculated through the following formulas.

For single read accesses:

A = (CSRDOFFTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period

C = RDCYCLETIME * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period

D = (RDCYCLETIME - ACCESSTIME) * GPMC_FCLK period

E = (CSRDOFFTIME - ACCESSTIME) * GPMC_FCLK period

For burst read accesses (where n is the page burst access number):

A = (CSRDOFFTIME - CSONTIME + (n - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period

C = (RDCYCLETIME + (n - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period

D = (RDCYCLETIME - (ACCESSTIME + (n - 1) * PAGEBURSTACCESSTIME) * GPMC_FCLK period

E = (CSRDOFFTIME - (ACCESSTIME + (n - 1) * PAGEBURSTACCESSTIME) * GPMC_FCLK period

For burst write accesses (where n is the page burst access number):

A = (CSWROFFTIME - CSONTIME + (n - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period

C = (WRCYCLETIME + (n - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period

D = (WRCYCLETIME - (ACCESSTIME + (n - 1) * PAGEBURSTACCESSTIME) * GPMC_FCLK period

E = (CSWROFFTIME - (ACCESSTIME + (n - 1) * PAGEBURSTACCESSTIME) * GPMC_FCLK period

For all accesses:

For CSn falling edge (CSn activated):

- Case where GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER = 0x0

  F = 0.5 * CSEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1

  F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and CSONTIME are odd) or (CLKACTIVATIONTIME and CSONTIME are even)

  F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period otherwise
- Case where GPMCFCLKDIVIDER = 0x2

  F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CSONTIME - CLKACTIVATIONTIME) is a multiple of 3

  F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSONTIME - CLKACTIVATIONTIME - 1) is a multiple of 3

  F = (2 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSONTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

For CSn rising edge (CSn de-activated) in reading mode:

- Case where GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER = 0x0

  F = 0.5 * CSEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1

  F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and CSRDOFFTIME are odd) or (CLKACTIVATIONTIME and CSRDOFFTIME are even)

  F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period otherwise
- Case where GPMCFCLKDIVIDER = 0x2

  F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CSRDOFFTIME - CLKACTIVATIONTIME) is a multiple of 3

  F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSRDOFFTIME - CLKACTIVATIONTIME - 1) is a multiple of 3

  F = (2 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSRDOFFTIME -

Copyright © 2011, Texas Instruments Incorporated

CLKACTIVATIONTIME - 2) is a multiple of 3

For CSn rising edge (CSn de-activated) in writing mode:

- Case where GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER = 0x0

  F = 0.5 * CSEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1

  F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and CSWROFFTIME are odd) or (CLKACTIVATIONTIME and CSWROFFTIME are even)

  F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period otherwise
- Case where GPMCFCLKDIVIDER = 0x2

  F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CSWROFFTIME - CLKACTIVATIONTIME) is a multiple of 3

  F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSWROFFTIME - CLKACTIVATIONTIME - 1) is a multiple of 3

  F = (2 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSWROFFTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

For ADVn falling edge (ADVn activated):

- Case where GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER = 0x0

  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1

  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and ADVONTIME are odd) or (CLKACTIVATIONTIME and ADVONTIME are even)

  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period otherwise
- Case where GPMCFCLKDIVIDER = 0x2

  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (ADVONTIME - CLKACTIVATIONTIME) is a multiple of 3

  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVONTIME - CLKACTIVATIONTIME - 1) is a multiple of 3

  G = (2 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVONTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

For ADVn rising edge (ADVn de-activated) in reading mode:

- Case where [1-0] GPMCFCLKDIVIDER = 0x0

  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1

  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and ADVRDOFFTIME are odd) or (CLKACTIVATIONTIME and ADVRDOFFTIME are even)

  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period otherwise
- Case where GPMCFCLKDIVIDER = 0x2

  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (ADVRDOFFTIME - CLKACTIVATIONTIME) is a multiple of 3

  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVRDOFFTIME - CLKACTIVATIONTIME - 1) is a multiple of 3

  G = (2 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVRDOFFTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

For ADVn rising edge (ADVn de-activated) in writing mode:

- Case where [1-0] GPMCFCLKDIVIDER = 0x0

  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1

  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and

Copyright © 2011, Texas Instruments Incorporated

ADVWROFFTIME are odd) or (CLKACTIVATIONTIME and ADVWROFFTIME are even)

G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period otherwise

- Case where GPMCFCLKDIVIDER = 0x2

  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (ADVWROFFTIME - CLKACTIVATIONTIME) is a multiple of 3

  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVWROFFTIME - CLKACTIVATIONTIME - 1) is a multiple of 3

  G = (2 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVWROFFTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

For OEn falling edge (OEn activated):

- Case where GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER = 0x0

  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period

- Case where GPMCFCLKDIVIDER = 0x1

  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and OEONTIME are odd) or (CLKACTIVATIONTIME and OEONTIME are even)

  H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period otherwise

- Case where GPMCFCLKDIVIDER = 0x2

  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period, when (OEONTIME - CLKACTIVATIONTIME) is a multiple of 3

  H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEONTIME - CLKACTIVATIONTIME - 1) is a multiple of 3

  H = (2 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEONTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

For OEn rising edge (OEn de-activated):

- Case where [1-0] GPMCFCLKDIVIDER = 0x0

  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period

- Case where GPMCFCLKDIVIDER = 0x1

  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and OEOFFTIME are odd) or (CLKACTIVATIONTIME and OEOFFTIME are even)

  H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period otherwise

- Case where GPMCFCLKDIVIDER = 0x2

  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period, when (OEOFFTIME - CLKACTIVATIONTIME) is a multiple of 3

  H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEOFFTIME - CLKACTIVATIONTIME - 1) is a multiple of 3

  H = (2 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEOFFTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

For WEn falling edge (WEn activated):

- Case where GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER = 0x0

  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period

- Case where GPMCFCLKDIVIDER = 0x1

  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and WEONTIME are odd) or (CLKACTIVATIONTIME and WEONTIME are even)

  I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period otherwise

- Case where GPMCFCLKDIVIDER = 0x2

  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period, when (WEONTIME - CLKACTIVATIONTIME) is a multiple of 3

  I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEONTIME - CLKACTIVATIONTIME -

Copyright © 2011, Texas Instruments Incorporated

1) is a multiple of 3

I = (2 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEONTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

Copyright © 2011, Texas Instruments Incorporated

For WEn rising edge (WEn de-activated):

- Case where [1-0] GPMCFCLKDIVIDER = 0x0

  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1

  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and WEOFFTIME are odd) or (CLKACTIVATIONTIME and WEOFFTIME are even)

  I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period otherwise
- Case where GPMCFCLKDIVIDER = 0x2

  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period, when (WEOFFTIME - CLKACTIVATIONTIME) is a multiple of 3

  I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEOFFTIME - CLKACTIVATIONTIME - 1) is a multiple of 3

  I = (2 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEOFFTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

For GPMC_ADVn low pulse duration:

- Read operation

  K = (ADVRDOFFTIME - ADVONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
- Write operation

  K = (ADVWROFFTIME - ADVONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period

For GPMC_WAIT invalid to first data latching GPMC_CLK edge:

L = WAITMONITORINGTIME * (GPMCFCLKDIVIDER + 1) * GPMC_FCLK period + GPMC_CLK period

Figure 7-45 shows a synchronous NOR single read simplified example where formulas are associated with signal waves.

7.1.3.9.1.3 Asynchronous NOR Flash Timing Parameters Formulas

This section lists all formulas to use in order to calculate asynchronous NOR timing parameters. This is the case when [11-10] DEVICETYPE = 0x0 and when READTYPE or WRITETYPE are set to asynchronous mode.

Table 7-44. Asynchronous NOR Formulas Description Table

Configuration Parameter	Unit	Description
A	ns	Pulse duration - GPMC_CSn low
B	ns	Delay time - GPMC_CSn valid to GPMC_ADVn_ALE invalid
C	ns	Delay time - GPMC_CSn valid to GPMC_OEn invalid (single read)
D	ns	Pulse duration - address bus valid - 2nd, 3rd and 4th accesses
E	ns	Delay time - GPMC_CSn valid to GPMC_WEn valid
F	ns	Delay time - GPMC_CSn valid to GPMC_WEn invalid
G	ns	Address invalid duration between 2 successive R/W accesses
H	ns	Setup time - read data valid before GPMC_OEn high
I	ns	Delay time - GPMC_CSn valid to GPMC_OEn invalid (burst read)
J	ns	Delay time - address bus valid to GPMC_CSn valid
		Delay time - data bus valid to GPMC_CSn valid
		Delay time - GPMC_BE0n_CLE/GPMC_BE1n valid to GPMC_CSn valid
K	ns	Delay time - GPMC_CSn valid to GPMC_ADVn_ALE valid
L	ns	Delay time - GPMC_CSn valid to GPMC_OEn valid
M	ns	Delay time - GPMC_CS valid to first data latching edge
N	ns	Pulse duration - GPMC_BE0n_CLE/GPMC_BE1n valid time
O	ns	Delay time - GPMC_CSn valid to GPMC_ADVn_ALE valid

The configuration parameters are calculated through the following formulas. Note that these formulas are not exhaustive.

GPMC_CSn low pulse:

For single read: A = (CSRDOFFTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period

For burst read: A = (CSRDOFFTIME - CSONTIME + (N - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period, where N = page burst access number

For single write: A = (CSWROFFTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period

For burst write: A = (CSWROFFTIME - CSONTIME + (N - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period, where N = page burst access number

GPMC_CSn valid to GPMC_ADVn_ALE invalid delay:

For reading: B = ((ADVRDOFFTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY - CSEXTRADELAY)) * GPMC_FCLK period

For writing: B = ((ADVWROFFTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY - CSEXTRADELAY)) * GPMC_FCLK period

C = ((OEOFFTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (OEEXTRADELAY - CSEXTRADELAY)) * GPMC_FCLK period

D = PAGEBURSTACCESSTIME * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period

E = ((WEONTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (WEEXTRADELAY - CSEXTRADELAY)) * GPMC_FCLK period

F = ((WEOFFTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (WEEXTRADELAY - CSEXTRADELAY)) * GPMC_FCLK period

G = CYCLE2CYCLEDELAY * GPMC_FCLK period

Copyright © 2011, Texas Instruments Incorporated

H = ((OEOFFTIME - ACCESSTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * OEEXTRADELAY) * GPMC_FCLK period

I = ((OEOFFTIME + (N - 1) * PAGEBURSTACCESSTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (OEEXTRADELAY - CSEXTRADELAY)) * GPMC_FCLK period, where N = page burst access number

J = (CSONTIME * (TIMEPARAGRANULARITY + 1) + 0.5 * CSEXTRADELAY) * GPMC_FCLK period

K = ((ADVONTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY - CSEXTRADELAY)) * GPMC_FCLK period

L = ((OEONTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (OEEXTRADELAY - CSEXTRADELAY)) * GPMC_FCLK period M = ((ACCESSTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) - 0.5 * CSEXTRADELAY) * GPMC_FCLK period

GPMC_BE0n_CLE/GPMC_BE1n pulse:

For single read: N = RDCYCLETIME * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period

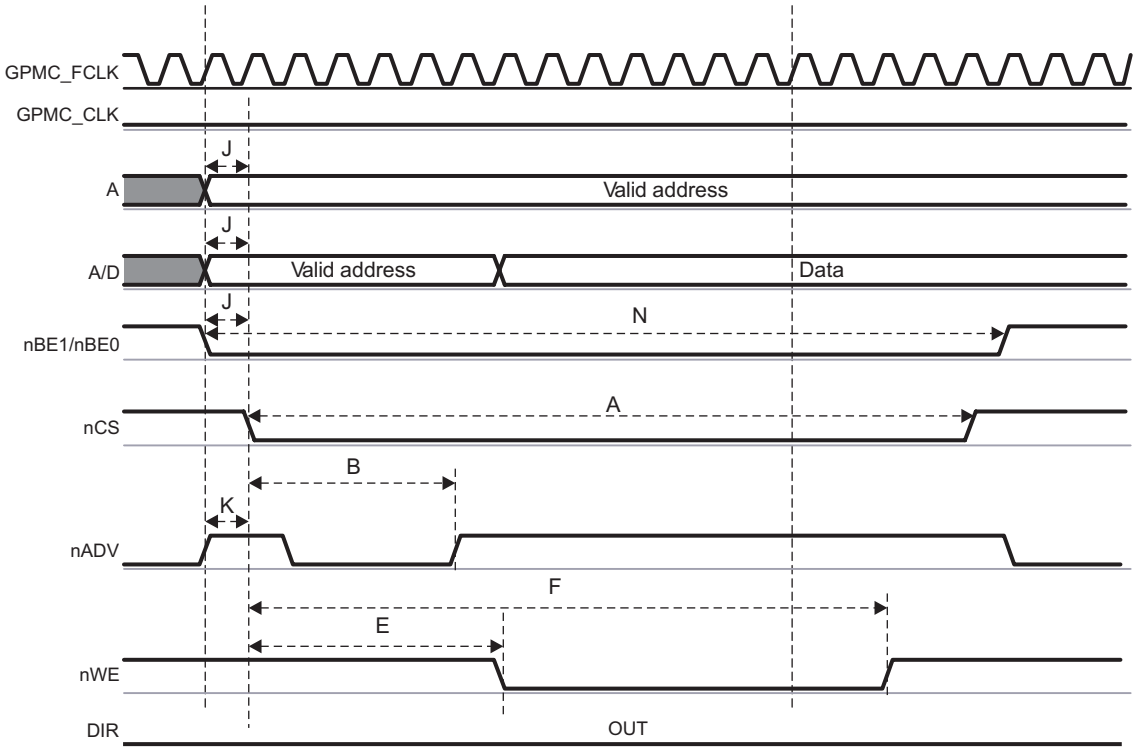
For burst read: N = (RDCYCLETIME + (N - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period, where N = page burst access number

For burst write: N = (WRCYCLETIME + (N - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period, where N = page burst access number

O = ((WRCYCLETIME + (N - 1) * PAGEBURSTACCESSTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY - CSEXTRADELAY)) * GPMC_FCLK period

Figure 7-46 shows an asynchronous NOR single write simplified example where formulas are associated with signal waves.

Figure 7-46. Asynchronous NOR Single Write Simplified Example



Write multiple access is not supported in asynchronous mode. If WRITEMULTIPLE is enabled with WRITETYPE as asynchronous, the GPMC processes single asynchronous accesses.

7.1.4 Use Cases

7.1.4.1 How to Set GPMC Timing Parameters for Typical Accesses

7.1.4.1.1 External Memory Attached to the GPMC Module

As discussed in the introduction to this chapter, the GPMC module supports the following external memory types:

- Asynchronous or synchronous, 8-bit or 16-bit-width memory or device
- 16-bit address/data-multiplexed or not multiplexed NOR flash device
- 8- or 16-bit NAND flash device

The following examples show how to calculate GPMC timing parameters by showing a typical parameter setup for the access to be performed.

The example is based on a 512-Mb multiplexed NOR flash memory with the following characteristics:

- Type: NOR flash (address/data-multiplexed mode)
- Size: 512M bits
- Data Bus: 16 bits wide
- Speed: 104 MHz clock frequency
- Read access time: 80 ns

7.1.4.1.2 Typical GPMC Setup

Table 7-45 lists some of the I/Os of the GPMC module.

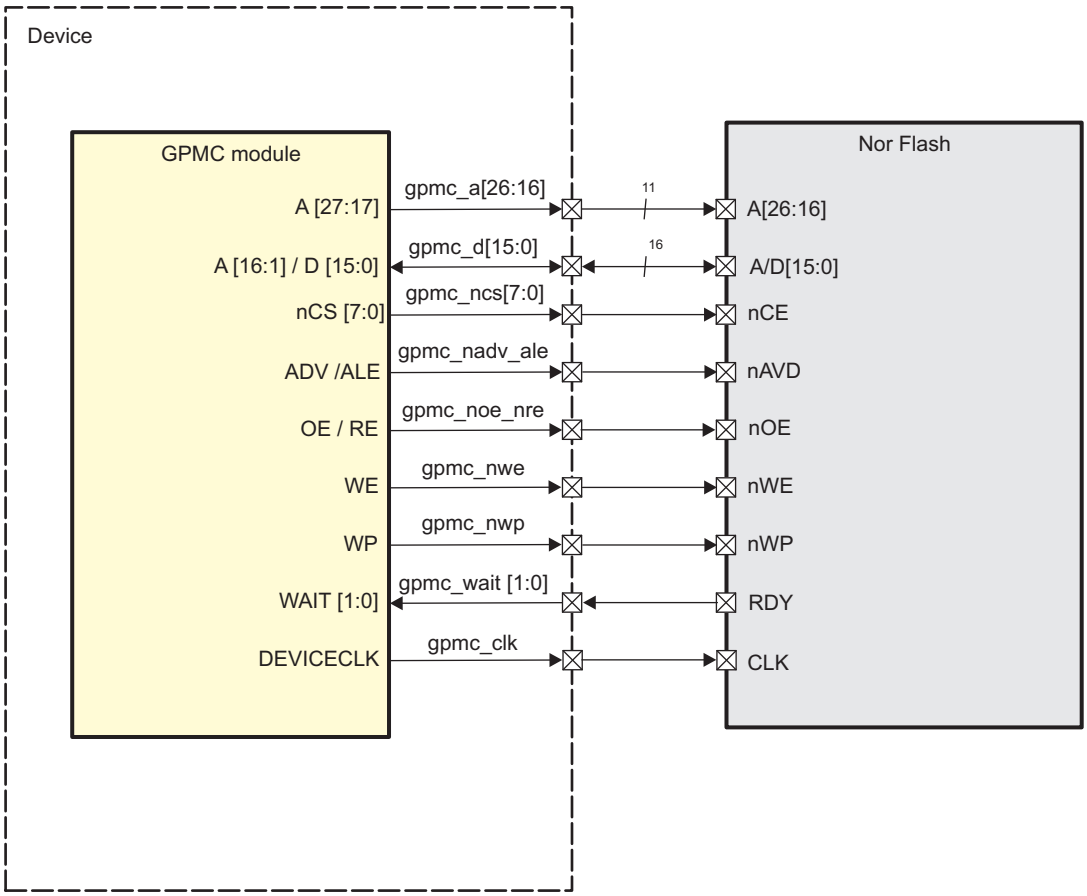
Table 7-45. GPMC Signals

Signal Name	I/O	Description
GPMC_FCLK	Internal	Functional and interface clock. Acts as the time reference.
GPMC_CLK	O	External clock provided to the external device for synchronous operations
GPMC_A[27:17]	O	Address
GPMC_AD[15: 0]	I/O	Data-multiplexed with addresses A[16:1] on memory side
GPMC_CSxn	O	Chip-select (where x = 0, or 1)
GPMC_ADVn_ALE	O	Address valid enable
GPMC_OE_REn	O	Output enable (read access only)
GPMC_WEn	O	Write enable (write access only)
GPMC_WAIT[1:0]	I	Ready signal from memory device. Indicates when valid burst data is ready to be read

Copyright © 2011, Texas Instruments Incorporated

Figure 7-47 shows the typical connection between the GPMC module and an attached NOR Flash memory.

Figure 7-47. GPMC Connection to an External NOR Flash Memory



The following sections demonstrate how to calculate GPMC parameters for three access types:

- Synchronous burst read
- Asynchronous read
- Asynchronous single write

Copyright © 2011, Texas Instruments Incorporated

7.1.4.1.3 GPMC Configuration for Synchronous Burst Read Access

The clock runs at 104 MHz (f = 104 MHz; T = 9, 615 ns).

Table 7-46 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Table 7-47 shows how to calculate timings for the GPMC using the memory parameters.

Figure 7-48 shows the synchronous burst read access.

Table 7-46. Useful Timing Parameters on the Memory Side

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCES	CSn setup time to clock	0
tACS	Address setup time to clock	3
tIACC	Synchronous access time	80
tBACC	Burst access time valid clock to output delay	5,2
tCEZ	Chip-select to High-Impedance	7
tOEZ	Output enable to High-Impedance	7
tAVC	ADVn setup time	6
tAVD	AVDn pulse	6
tACH	Address hold time from clock	3

The following terms, which describe the timing interface between the controller and its attached device, are used to calculate the timing parameters on the GPMC side:

- Read Access time (GPMC side): Time required to activate the clock + read access time requested on the memory side + data setup time required for optimal capture of a burst of data
- Data setup time (GPMC side): Ensures a good capture of a burst of data (as opposed to taking a burst of data out). One word of data is processed in one clock cycle (T = 9,615 ns). The read access time between 2 bursts of data is tBACC = 5,2 ns. Therefore, data setup time is a clock period - tBACC = 4,415 ns of data setup.
- Access completion (GPMC side): (Different from page burst access time) Time required between the last burst access and access completion: CSn/OEn hold time (CSn and OEn must be released at the end of an access. These signals are held to allow the access to complete).
- Read cycle time (GPMC side): Read Access time + access completion
- Write cycle time for burst access: Not supported for NOR flash memory

7.1.4.1.4 GPMC Configuration for Asynchronous Read Access

The clock runs at 104 MHz (f = 104 MHz; T = 9, 615 ns).

Table 7-48 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Table 7-49 shows how to calculate timings for the GPMC using the memory parameters.

Figure 7-49 shows the asynchronous read access.

Table 7-48. AC Characteristics for Asynchronous Read Access

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCE	Read Access time from CSn low	80
tAAVDS	Address setup time to rising edge of ADVn	3
tAVDP	ADVn low time	6
tCAS	CSn setup time to ADVn	0
tOE	Output enable to output valid	6
tOEZ	Output enable to High-Impedance	7

Use the following formula to calculate the RdCycleTime parameter for this typical access:

RdCycleTime = RdAccessTime + AccessCompletion = RdAccessTime + 1 clock cycle + tOEZ

- First, on the memory side, the external memory makes the data available to the output bus. This is the memory-side read access time defined in Table 7-49: the number of clock cycles between the address capture (ADVn rising edge) and the data valid on the output bus.

The GPMC requires some hold time to allow the data to be captured correctly and the access to be finished.

- To read the data correctly, the GPMC must be configure to meet the data setup time requirement of the memory; the GPMC module captures the data on the next rising edge. This is access time on the GPMC side.
- There must also be a data hold time for correctly reading the data (checking that there is no OEn/CSn deassertion while reading the data). This data hold time is 1 clock cycle (that is, AccessTime + 1).
- To complete the access, OEn/CSn signals are driven to high-impedance. AccessTime + 1 + tOEZ is the read cycle time.
- Addresses can now be relatched and a new read cycle begun.

Table 7-49. GPMC Timing Parameters for Asynchronous Read Access

Parameter Name on GPMC side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Register Configurations
ClkActivationTime	n/a (asynchronous mode)			
AccessTime	round max (tCE)	80	9	ACCESSTIME = 9h
PageBurstAccessTime	n/a (single access)			
RdCycleTime	AccessTime + 1cycle + tOEZ	96, 615	11	RDCYCLETIME = Bh
CsOnTime	tCAS	0	0	CSONTIME = 0
CsReadOffTime	AccessTime + 1 cycle	89, 615	10	CSRDOFFTIME = Ah
AdvOnTime	tAAVDS	3	1	ADVONTIME = 1
AdvRdOffTime	tAAVDS + tAVDP	9	1	ADVRDOFFTIME = 1
OeOnTime	OeOnTime ≥ AdvRdOffTime (multiplexed mode)	-	3, for instance	OEONTIME = 3h
OeOffTime	AccessTime + 1cycle	89, 615	10	OEOFFTIME = Ah

Figure 7-49. Asynchronous Single Read Access (Timing Parameters in Clock Cycles)

7.1.4.1.5 GPMC Configuration for Asynchronous Single Write Access

The clock runs at 104 MHz: (f = 104 MHz; T = 9, 615 ns).

Table 7-50 shows how to calculate timings for the GPMC using the memory parameters.

Table 7-51 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Figure 7-50 shows the synchronous burst write access.

Table 7-50. AC Characteristics for Asynchronous Single Write (Memory Side)

AC Characteristics on the Memory Side	Description	Duration (ns)
tWC	Write cycle time	60
tAVDP	ADVn low time	6
tWP	Write pulse width	25
tWPH	Write pulse width high	20
tCS	CSn setup time to WEn	3
tCAS	CSn setup time to ADVn	0
tAVSC	ADVn setup time	3

For asynchronous single write access, write cycle time is WrCycleTime = WeOffTime + AccessCompletion = WeOffTime + 1. For the AccesCompletion, the GPMC requires 1 cycle of data hold time (CSn de-assertion).

Copyright © 2011, Texas Instruments Incorporated

Table 7-51. GPMC Timing Parameters for Asynchronous Single Write

Parameter Name on GPMC side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Register Configurations
ClkActivationTime	n/a (asynchronous mode)			
AccessTime	Applicable only to WAITMONITORING (the value is the same as for read access)			
PageBurstAccessTime	n/a (single access)			
WrCycleTime	WeOffTime + AccessCompletion	57, 615	6	WRCYCLETIME = 6h
CsOnTime	tCAS	0	0	CSONTIME = 0
CsWrOffTime	WeOffTime + 1	57, 615	6	CSWROFFTIME = 6h
AdvOnTime	tAVSC	3	1	ADVONTIME = 1
AdvWrOffTime	tAVSC + tAVDP	9	1	ADVWROFFTIME = 1
WeOnTime	tCS	3	1	WEONTIME = 1
WeOffTime	tCS + tWP + tWPH	48	5	WEOFFTIME = 5h

7.1.4.2 How to Choose a Suitable Memory to Use With the GPMC

This section is intended to help the user select a suitable memory device to interface with the GPMC controller.

7.1.4.2.1 Supported Memories or Devices

NAND flash and NOR flash architectures are the two flash technologies. The GPMC supports various types of external memory or device, basically any one that supports NAND or NOR protocols:

- 8- and 16-bit width asynchronous or synchronous memory or device (8-bit: non burst device only)
- 16-bit address and data multiplexed NOR flash devices (pSRAM, , ...)
- 8- and 16-bit NAND flash device

7.1.4.2.2 Memory Pin Multiplexing

This section highlights the interfacing differences of the GPMC supported memories (see Table 7-52).

Table 7-52. Supported Memory Interfaces

7.1.4.2.3 NAND Interface Protocol

NAND flash architecture, introduced in 1989, is a flash technology. NAND is a page-oriented memory device, that is, read and write accesses are done by pages. NAND achieves great density by sharing common areas of the storage transistor, which creates strings of serially connected transistors (in NOR devices, each transistor stands alone). Thanks to its high density NAND is best suited to devices requiring high capacity data storage, such as pictures, music, or data files. NAND non-volatility, makes of it a good storage solution for many applications where mobility, low power, and speed are key factors. Low pin count and simple interface are other advantages of NAND.

Table 7-53 summarizes the NAND interface signals level applied to external device or memories.

Table 7-53. NAND Interface Bus Operations Summary

Bus Operation	CLE	ALE	CEn	WEn	REn	WPn
Read (cmd input)	H	L	L	RE	H	x
Read (add input)	L	H	L	RE	H	x
Write (cmd input)	H	L	L	RE	H	H
Write (add input)	L	H	L	RE	H	H
Data input	L	L	L	RE	H	H
Data output	L	L	L	H	FE	x
Busy (during read)	x	x	H	H	H	x
Busy (during program)	x	x	x	x	x	H
Busy (during erase)	x	x	x	x	x	H
Write protect	x	x	x	x	x	L
Stand-by	x	x	H	x	x	H/L

7.1.4.2.4 NOR Interface Protocol

NOR flash architecture, introduced in 1988, is a flash technology. Unlike NAND, which is a sequential access device, NOR is directly addressable; i.e., it is designed to be a random access device. NOR is best suited to devices used to store and run code or firmware, usually in small capacities. While NOR has fast read capabilities it has slow write and erase functions compared to NAND architecture.

Table 7-54 summarizes the NOR interface signals level applied to external device or memories.

Table 7-54. NOR Interface Bus Operations Summary

Bus Operation	CLK	ADVn	CSn	OEn	WEn	WAIT	DQ[15:0]
Read (asynchronous)	x	L	L	L	H	Asserted	Output
Read (synchronous)	Running	L	L	L	H	Driven	Output
Read (burst suspend)	Halted	x	L	H	H	Active	Output
Write	x	L	L	H	L	Asserted	Input
Output disable	x	x	L	H	H	Asserted	High-Z
Standby	x	x	H	x	x	High-Z	High-Z

7.1.4.2.5 Other Technologies

Other supported device type interact with the GPMC through the NOR interface protocol.

OneNAND Flash is a high-density and low-power memory device. It is based on single- or multi-level-cell NAND core with SRAM and logic, and interfaces as a synchronous NOR Flash, plus has synchronous write capability. It reads faster than conventional NAND and writes faster than conventionnal NOR flash. Hence, it is appropriate for both mass storage and code storage.

pSRAM stands for pseudo-static random access memory. pSRAM is a low-power memory device for mobile applications. pSRAM is based on the DRAM cell with internal refresh and address control features, and interfaces as a synchronous NOR Flash, plus has synchronous write capability.

7.1.4.2.6 Supported Protocols

The GPMC supports the following interface protocols when communicating with external memory or external devices:

- Asynchronous read/write access
- Asynchronous read page access (4-8-16 Word16)
- Synchronous read/write access
- Synchronous read burst access without wrap capability (4-8-16 Word16)
- Synchronous read burst access with wrap capability (4-8-16 Word16)

7.1.4.2.7 GPMC Features and Settings

This section lists GPMC features and settings:

- Supported device type: up to four NAND or NOR protocol external memories or devices
- Operating Voltage: 3.3V
- Maximum GPMC addressing capability: 512 MBytes divided into eight chip-selects
- Maximum supported memory size: 256 MBytes (must be a power-of-2)
- Minimum supported memory size: 16 MBytes (must be a power-of-2). Aliasing occurs when addressing smaller memories.
- Data path to external memory or device: 8- and 16-bit wide
- Burst and page access: burst of 4-8-16 Word16
- Supports bus keeping
- Supports bus turn around

Copyright © 2011, Texas Instruments Incorporated

7.1.5 Registers

Table 7-55 provides a summary of the GPMC registers. All GPMC registers are aligned to 32-bit address boundaries. All register file accesses, except the GPMC_NAND_DATA_i register, are little-endian. If the GPMC_NAND_DATA_i register is accessed, the endianness is access-dependent.

In this section, i corresponds to the chip-select number, i = 0 to 6.

Table 7-55. GPMC Registers

R-0	

15	13	12	4	3	1	0
Reserved		TIMEOUTSTARTVALUE		Reserved		TIMEOUTENABLE
R-0		R/W-0		R-0		R/W-0

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 7-61. GPMC_TIMEOUT_CONTROL Field Descriptions

Bit	Field	Value	Description
31-13	Reserved	0	Reserved
12-4	TIMEOUTSTARTVALUE	0-1FFh	Start value of the time-out counter (000 corresponds to 0 GPMC.FCLK cycle, 1h corresponds to 1 GPMC.FCLK cycle, and 1FFh corresponds to 511 GPMC.FCLK cycles)
3-1	Reserved	0	Reserved
0	TIMEOUTENABLE		Enable bit of the TimeOut feature
		0	TimeOut feature is disabled
		1	TimeOut feature is enabled

7.1.5.7 GPMC_ERR_ADDRESS

The GPMC_ERR_ADDRESS register stores the address of the illegal access when an error occurs.

Figure 7-57. GPMC_ERR_ADDRESS

31	30	0
Rsvd	ILLEGALADD	
R-0	R/W-0	

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 7-62. GPMC_ERR_ADDRESS Field Descriptions

Bit	Field	Value	Description
31	Reserved	0	Reserved
30-0	ILLEGALADD	0-7FFF FFFFh	Address of illegal access: A30 (0 for memory region, 1 for GPMC register region) and A29-A0 (1GByte maximum)

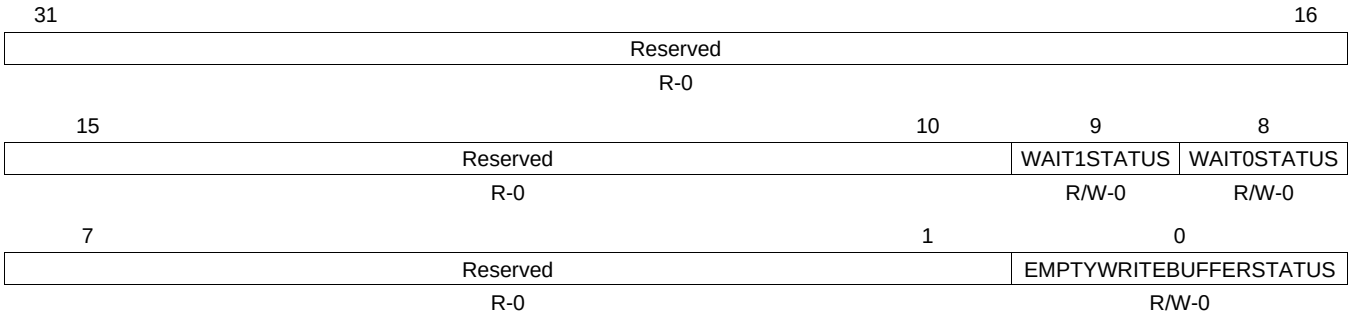
7.1.5.10 GPMC_STATUS

The status register provides global status bits of the GPMC.

Figure 7-60. GPMC_STATUS



LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 7-65. GPMC_STATUS Field Descriptions

Bit	Field	Value	Description
31-10	Reserved	0	Reserved
9	WAIT1STATUS		Is a copy of input pin WAIT1. (Reset value is WAIT1 input pin sampled at IC reset)
		0	WAIT1 asserted (inactive state)
		1	WAIT1 de-asserted
8	WAIT0STATUS		Is a copy of input pin WAIT0. (Reset value is WAIT0 input pin sampled at IC reset)
		0	WAIT0 asserted (inactive state)
		1	WAIT0 de-asserted
7-1	Reserved	0	Reserved
0	EMPTYWRITEBUFFERSTATUS		Stores the empty status of the write buffer
		0	Write Buffer is not empty
		1	Write Buffer is empty

Copyright © 2011, Texas Instruments Incorporated

7.1.5.11 GPMC_CONFIG1_i

The configuration 1 register sets signal control parameters per chip select.

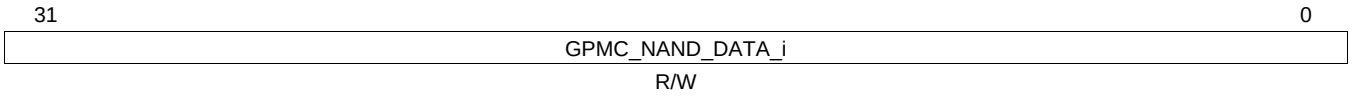
Table 7-74. GPMC_NAND_ADDRESS_i Field Descriptions

Bit	Field	Value	Description
31-0	GPMC_NAND_ADDRESS_i	0-FFFF FFFFh	Writing data at the GPMC_NAND_ADDRESS_i location places the data as the NAND partial address value on the bus, using a regular asynchronous write access.

7.1.5.20 GPMC_NAND_DATA_i

This register is not a true register, just an address location.

Figure 7-70. GPMC_NAND_DATA_i



LEGEND: R/W = Read/Write; R = Read only; W = Write only; -n = value after reset

Table 7-75. GPMC_NAND_DATA_i Field Descriptions

Bit	Field	Value	Description
31-0	GPMC_NAND_DATA_i	0-FFFF FFFFh	Reading data from the GPMC_NAND_DATA_i location or from any location in the associated chip-select memory region activates an asynchronous read access.

7.2 OCMC-RAM

7.2.1 Introduction

7.2.1.1 OCMC RAM Features

The on-chip memory controller consists of two separate modules that are OCP to ACE wrappers for ACE memories. The first wrapper is for a ROM; the second is for a RAM. Each wrapper has its own dedicated interface to the L3 interconnect. This device uses only the RAM wrapper which supports both BRGS single port and GLG single port CRAM.

- 32- or 64-bit width
- Initial latency max 2 cycles (due to OCP to memory core wrapper).
- Multiple memory bank control based on address MSBs
- Full OCP IP 2.0 Burst support. No wait state.

7.2.1.2 Unsupported OCMC RAM Features

For this device, the OCMC RAM implementation does not support parity.

Copyright © 2011, Texas Instruments Incorporated

7.2.2 Integration

This device includes a single instantiation of the on-chip memory controller interfacing to a single 64-K bank of RAM.

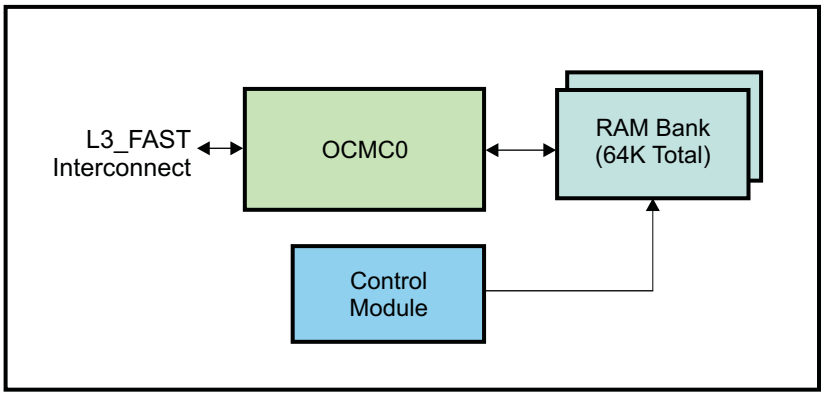

Figure 7-87. OCMC RAM Integration

7.2.2.1 OCMC RAM Connectivity Attributes

The general connectivity attributes for the OCMC RAM modules are summarized in Table 7-92.

Table 7-92. OCMC RAM Connectivity Attributes

Attributes	Type
Power Domain	Peripheral Domain
Clock Domain	PD_PER_L3_GCLK
Reset Signals	PER_DOM_RST_N
Idle/Wakeup Signals	Smart Idle
Interrupt Requests	None
DMA Requests	None
Physical Address	L3 Fast slave port

7.2.2.2 OCMC RAM Clock and Reset Management

The OCMC module uses a single clock for the module and its OCP interface.

Table 7-93. OCMC RAM Clock Signals

Clock Signal	Max Freq	Reference / Source	Comments
prcm_ocmc_clock Interface / Functional clock	200 MHz	CORE_CLKOUTM4	pd_per_l3_gclk From PRCM

7.2.2.3 OCMC RAM Pin List

The OCMC RAM module does not include any external interface pins.

Copyright © 2011, Texas Instruments Incorporated

7.3 EMIF

7.3.1 Introduction

7.3.1.1 FeatuUpdated res

The general features of the EMIF module are as follows:

- 16-bit data path to external SDRAM memory
- One 128-bit OCPIP 2.2 interface
- Support for the following memory types:
  - mDDR (LPDDR1)
  - DDR2
  - DDR3

External memory configurations supported:

- Memory device capacity
  - Up to 1G Byte addressability
- Flexible bank/row/column/chip-select address multiplexing schemes
- Device driver strength feature for mobile DDR supported
- Supports following CAS latencies:
  - DDR2 => 2, 3, 4, 5, 6, and 7
  - DDR3 => 5, 6, 7, 8, 9, 10, and 11
  - mDDR => 2, 3, and 4
- Supports following number of internal banks:
  - DDR2 => 1, 2, 4, and 8
  - DDR3 => 1, 2, 4, and 8
  - mDDR => 1, 2, and 4
- Supports 256, 512, 1024, and 2048-word page sizes
- Supports burst length of 8 (sequential burst)
- Write/read leveling/calibration and data eye training in conjunction with DID
- Self Refresh and Power-Down modes for low power:
  - Flexible OCP to DDR address mapping to support Partial Array Self Refresh in LPDDR1, DDR2 and DDR3.
  - Temperature Controlled Self Refresh for LPDDR1 and DDR3 having on-chip temperature sensor.
- Periodic ZQ calibration for DDR3
- ODT on DDR2 and DDR3
- Prioritized refresh scheduling
- Programmable SDRAM refresh rate and backlog counter
- Programmable SDRAM timing parameters
- Big and little endian modes

Copyright © 2011, Texas Instruments Incorporated

7.3.1.2 Unsupported EMIF Features

The following EMIF4DC module features are not supported in this device.

Table 7-94. Unsupported EMIF Features

Feature	Reason
32-bit data	Only 16 bits pinned out
Multiple DDR banks	Only 1 CS/ODT pinned out
DDR2 CAS Latency 2	Not supported by DID

Copyright © 2011, Texas Instruments Incorporated

7.3.2 Integration

7.3.2.1 EMIF Connectivity Attributes

The general connectivity attributes for the EMIF are shown in Table 7-95.

Table 7-95. EMIF Connectivity Attributes

Attributes	Type
Power Domain	Peripheral Domain
Clock Domain	PD_PER_L3_GCLK (OCP) PD_PER_EMIF_GCLK (Func)
Reset Signals	POR_N
Idle/Wakeup Signals	Smart Idle
Interrupt Requests	1 interrupt to MPU Subsystem (DDRERR0)
DMA Requests	None
Physical Address	L3 Fast Slave Port

7.3.2.2 EMIF Clock Management

The EMIF4 OCP interface (ocp_clk) is clocked by the L3 Fast clock sourced from the Core PLL. The DDR Command and Data macros are clocked by the DDR PLL. The PRCM divides this clock by two to create the EMIF functional clock (m_clk).

The OCP and functional clocks may be asynchronous because synchronization is managed in the EMIF4 internal FIFO (EMIF4 is set in asynchronous mode).

Table 7-96. EMIF Clock Signals

Clock Signal	Max Freq	Reference Source	Comments
ocp_clk (Interface clock)	200 Mhz	CORE_CLKOUTM4	pd_per_l3_gclk From PRCM
m_clk (EMIF functional clock)	100 Mhz	DDR PLL CLKOUT / 2	pd_per_emif_gclk From PRCM
cmd0_dfi_clk cmd1_dfi_clk cmd2_dfi_clk data0_dfi_clk data1_dfi_clk (Macro clocks)	200 MHz	DDR PLL CLKOUT	clkout_po From DDR PLL

7.3.2.3 EMIF Pin List

The EMIF/DDR external interface signals are shown in Table 7-97.

Table 7-97. EMIF Pin List

Pin	Type	Description

7.3.3 Functional Description

7.3.3.1 Signal Descriptions

The DDR2/3/mDDR memory controller signals are shown in Figure 7-88 and described in Table 7-98. The following features are included:

- The maximum width for the data bus (DDR_D[15:0]) is 16-bits
- The address bus (DDR_A[15:0]) is 16-bits wide with an additional 3 bank address pins (DDR_BA[2:0])
- Two differential output clocks (DDR_CK and DDR_nCK) driven by internal clock sources
- Command signals: Row and column address strobe (DDR_RASn and DDR_CASn), write enable strobe

(DDR_WEn), data strobe (DDR_DQS[1:0] and DDR_DQSn[1:0]), and data mask (DDR_DQM[1:0]).

- One chip select signal (DDR_CSN0) and one clock enable signal (DDR_CKE)
- One on-die termination output signals (DDR_ODT).

Figure 7-88. DDR2/3/mDDR Memory Controller Signals

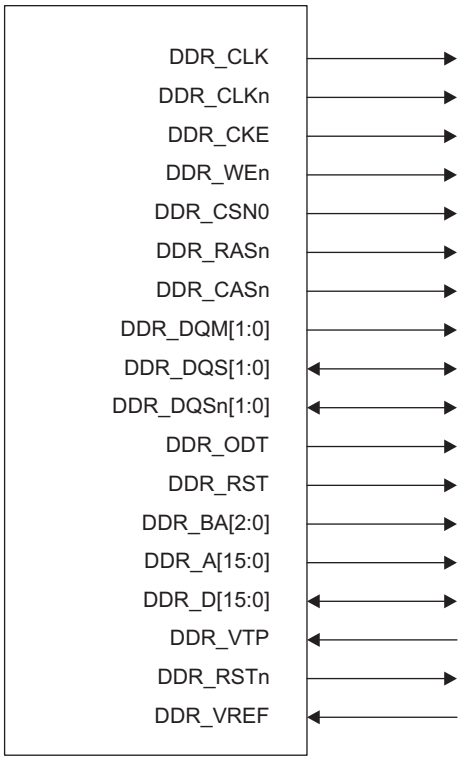

Table 7-98. DDR2/3/mDDR Memory Controller Signal Descriptions

Pin	Description
DDR_D[15:0]	Bidirectional data bus. Input for data reads and output for data writes.
DDR_A[15:0]	External address output.
DDR_CSN0	Chip select output.
DDR_DQM[1:0]	Active-low output data mask.
DDR_CLK/DDR_CLKn	Differential clock outputs. All DDR2/3/mDDR interface signals are synchronous to these clocks.
DDR_CKE	Clock enable. Used to select Power-Down and Self-Refresh operations.
DDR_CASn	Active-low column address strobe.
DDR_RASn	Active-low row address strobe.
DDR_WEn	Active-low write enable.

Table 7-98. DDR2/3/mDDR Memory Controller Signal Descriptions (continued)

Pin	Description
DDR_DQS[1:0]/DDR_DQSn[1:0]	Differential data strobe bidirectional signals. Edge-aligned inputs on reads and center-aligned outputs on writes.
DDR_ODT	On-die termination signal to external DDR2/3 SDRAM. ODT is not supported for mDDR.
DDR_BA[2:0]	Bank-address control outputs.
DDR_VREF	Memory Controller reference voltage. This voltage must be supplied externally. See the device-specific data manual for more details.
DDR_VTP	DDR2/3/mDDR VTP Compensation Resistor Connection.
DDR_RESETn	Reset output. Asynchronous reset for DDR3 devices.

7.3.3.2 Clock Control

DDR2/3/mDDR clock is derived directly from the DDR PLL's VCO output. The frequency of DDR_CLK can be determined by using the following formula:

DDR_CLK frequency = (DDRPLL input clock frequency x mulitplier)/((pre-divider+1)*post-divider)

The second output clock of the DDR2/3/mDDR memory controller DDR_CLKn, is the inverse of DDR_CLK. You can change the muliplier, pre-divier and post-divider to get the desired DDR_CLK frequency.

For detailed information on DDRPLL, see Section 8.1, *Power Management and Clock Module (PRCM)*.

7.3.3.3 DDR2/3/mDDR Memory Controller Subsytem Overview

The DDR2/3/mDDR memory controller can gluelessly interface to most standard DDR2/3/mDDR SDRAM devices and supports such features as self-refresh mode and prioritized refresh. In addition, it provides flexibility through programmable parameters such as the refresh rate, CAS latency, and many SDRAM timing parameters. The DDR2/3/mDDR subsystem consists of the following:

- DDR2/3/mDDR memory controller
- Command macro
- Data macro
- VTP controller macro
- IOs for DQS gate

The subsystem supports JEDEC standard compliant DDR2/DDR3 and mDDR(LPDRR1)devices. It does not support CAS latency of 2 for DDR2 due to data and command macro limitations. It supports a 128-bit wide OCP interface on the core side for programmability. The subsystem can be used to connect to 16-bit memory devices.

Figure 7-89 shows the DDR2/3/mDDR subsystem block diagram.

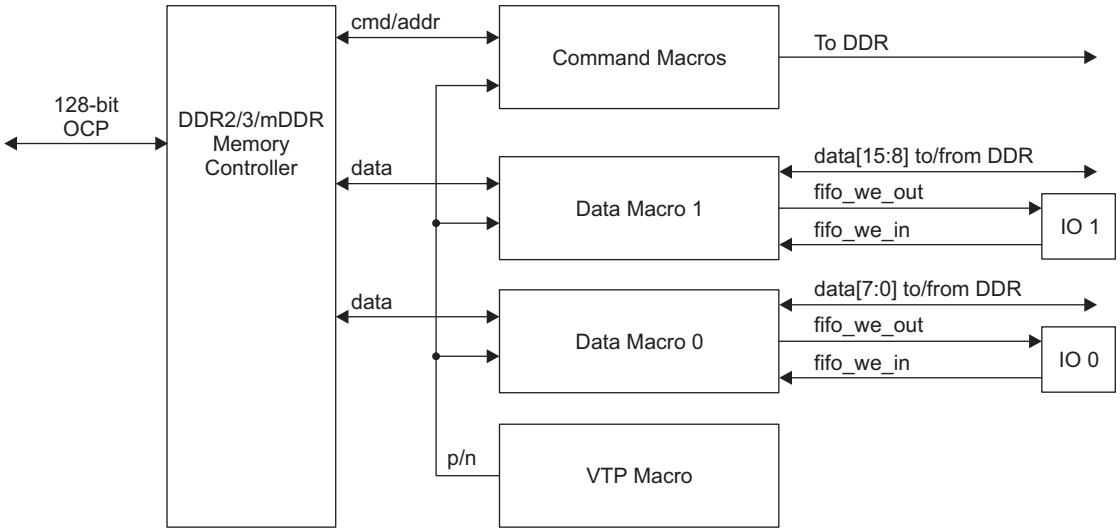
Figure 7-89. DDR2/3/mDDR Subsystem Block Diagram



Where
fifo_we_out = DQS enable output for timing match between DQS and system (Memory) clock.
fifo_we_in = DQS enable input for timing match between DQS and system (Memory) clock.

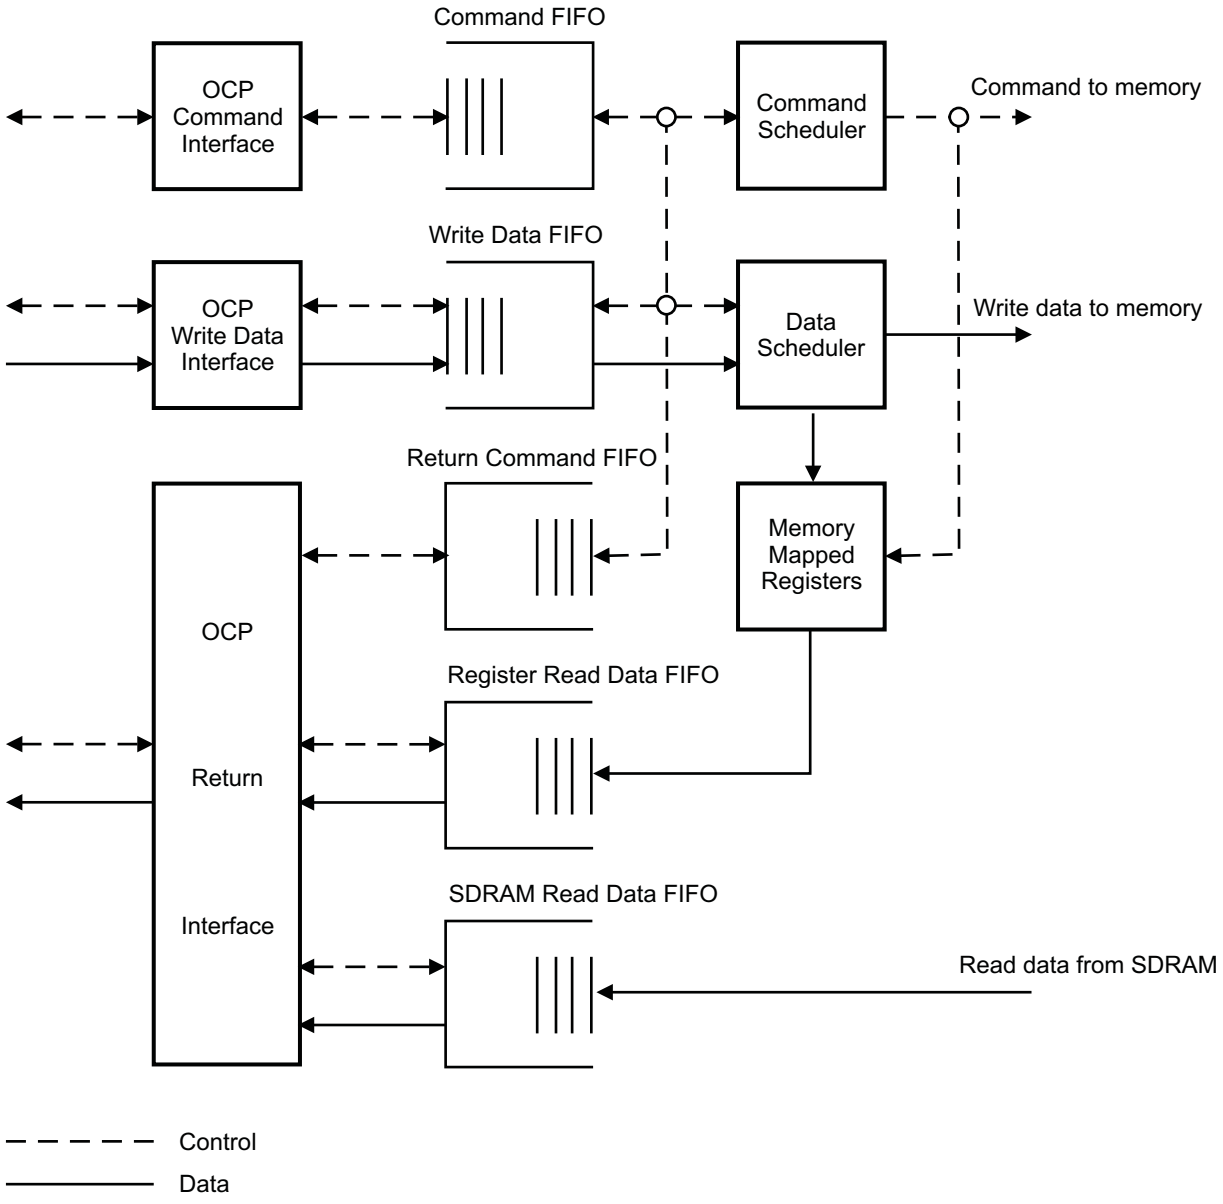
7.3.3.3.1 DDR2/3/mDDR Memory Controller Interface

To move data efficiently from on-chip resources to external DDR2/3/mDDR SDRAM device, the DDR2/3/mDDR memory controller makes use of a command FIFO, a write data FIFO, a return command FIFO, and two Read Data FIFOs. Purpose of each FIFO is described below.

Figure 7-90 shows the block diagram of the DDR2/3/mDDR memory controller FIFOs. Commands, write data, and read data arrive at the DDR2 memory controller parallel to each other. The same peripheral bus is used to write and read data from external memory as well as internal memory-mapped registers.

Copyright © 2011, Texas Instruments Incorporated

Figure 7-90. DDR2/3/mDDR Memory Controller FIFO Block Diagram



The command FIFO stores all the commands coming in on the OCP command interface.

The Write Data FIFO stores the write data for all the write transactions coming in on the OCP write data interface.

The Return Command FIFO stores all the return transactions that are to be issued to the OCP return interface. These include the write status return and the read data return commands.

There are two Read Data FIFOs that store the read data to be sent to the OCP return interface. One Read Data FIFO stores read data from the memory mapped registers and other Read Data FIFO stores read data from external memory.

7.3.3.3.2 Data Macro

The data macro consists of 8 data channels, one pair of complementary strobes (one pair for 8 bits of data), and one data mask channel (one for 8 bits of data).

The data macros consists of PHY Data Macro, DLLs and IOs integrated into a macro.

Copyright © 2011, Texas Instruments Incorporated

The data macro is a bidirectional interface. It is used to transmit data from the memory controller to the external memory chip during a write operation and receive data from memory and transmit it to the memory controller during a read operation.

During a write operation, the data macro translates 32/16-bit words from memory controller to 8-bit words and transmits them at double the bit rate to the memory along with the strobe. The strobe is center-aligned to the data. Data can be prevented from writing to the memory using data mask signal.

During a read operation, the data macro receives 8-bit DDR data along with the strobe and converts it to 32/16- bit words and transmits them to the memory controller along with the read-valid signals.

7.3.3.3.3 Command Macro

It consists of PHY Command Macro, DLLs and the IOs integrated together. The command macro acts as a unidirectional macro that transmits address and control bits from memory controller to the memory chip. The clocks DDR_CLK and DDR_CLKn are used by the memory to register the command and address transmitted on the transmit channels. All address and control signals are transmitted clock-centered with respect to DDR_CLK and DDR_CLKn. The memory, on the positive edge of DDR_CLK and the negative edge of DDR_CLKn, samples all address and control signals.

7.3.3.3.4 VTP Controller Macro

The VTP controller macro evaluates silicon performance at current voltage, temperature, and process (VTP) to enable IO drivers to set constant predetermined output driver impedance. The controller operates by comparing driver impedances to the external reference resistor and adjusting driver impedance to obtain an impedance match. VTP Controller supports the following features:

- The VTP controller generates information regarding the Voltage, temperature, and process(VTP) on a chip to be shared with the device's IO drivers
- Requires a Clock input from the core running at 20MHz or less
- 56 Clock cycles are needed to guarantee the VTP outputs are initially set after reset is removed
- Can be used in static or dynamic update mode of operation
- The VTP controller has internal noise filtering which allows it to control spurious update requests due to noise

Impedance of the drivers and terminations must be updated often even while in operation. In such scenarios where Voltage and Temperature are variables VTP macro can be configured in dynamic update mode. In contrast, static mode of operation does not allow dynamic calibration of IO impedance, and hence consumes lesser power compared to dynamic update mode.

It is possible that under noisy conditions, dynamic update controller can generate too frequent update requests. Noise can cause the controller to request a change in the impedance that can again be quickly reversed on subsequent clock cycles. To prevent the controller from making excessive numbers of impedance changes, a digital filter is included which can be configured to regulate the update rate. For example if the user configures the filter value as F2=0,F1=1 and F0=1, then an impedance update will be performed only if four successive update requests are generated from the VTP controller. It is recommended to use a filter value of 011'b.

Table 7-99 shows the configuration details of the digital filter.

Table 7-99. Digital Filter Configuration

F2	F1	F0	Description
0	0	0	Off
0	0	1	Update on 2 consecutive update requests
0	1	0	Update on 3 consecutive update requests
0	1	1	Update on 4 consecutive update requests
1	0	0	Update on 5 consecutive update requests
1	0	1	Update on 6 consecutive update requests
1	1	0	Update on 7 consecutive update requests

Table 7-99. Digital Filter Configuration (continued)

F2	F1	F0	Description
1	1	1	Update on 8 consecutive update requests

7.3.3.3.5 DQS-Gate IOs

To effectively model the I/O delay on the DQS gating signal during a read request (the DQS receiver and the CLK driver I/Os), the signal is expected to be looped on a single I/O connecting fifo_we_in to fifo_we_out. The board and memory delay, being fairly constant across PTV variations, are calibrated within the IDID using a compensated delay line. The loop-back is done at the die level without bringing the signals out to the package level. Each Data Macro supports delay compensation independent of each other.

The data and command macros are responsible for System level flight time compensation. The following controls are supported by the DDR2/3/mDDR controller Sub System.

- Aligning DDR_DQS w.r.t DDR_CLK during Write Cycle: For DDR3 operation, initiate the write leveling state machine on each rank in turn to capture the proper delay settings to align DDR_DQS with DDR_CLK clock for each memory chip. If one wants to do this in a manual way one can write to the control register that controls the delay of DDR_DQS vs DDR_CLK Clock position. To produce a given amount of skew to center the DDR_DQS vs. Clock at the SDRAM the following register can be programmed.

Data Macro 0/1 Write DQS Slave Ratio Register=256 x ([command delay] – [DDR_DQS delay]) / DDR_CLK Clock period.

- Aligning ADDR/CMD w.r.t DDR_CLK
- Aligning DDR_DQ[15:0] w.r.t DDR_DQS during Write Operation
- Offset DDR_D[15:0] w.r.t DDR_DQS during Read Operation
- Align FIFO WE Window

7.3.3.4 Address Mapping

The DDR2/3/mDDR memory controller views external DDR2/3/mDDR SDRAM as one continuous block of memory. This statement is true regardless of the number of memory devices located on the chip select space. The DDR2/3/mDDR memory controller receives DDR2/3/mDDR memory access requests along with a 32-bit logical address from the rest of the system. In turn, DDR2/3/mDDR memory controller uses the logical address to generate a row/page, column, and bank address for the DDR2/3/mDDR SDRAM. The number of column, row and bank address bits used is determined by the IBANK, RSIZE and PAGESIZE fields (see Table 7-100). The DDR2/3/mDDR memory controller uses up to 16 bits for the row/page address.

Table 7-100. IBANK, RSIZE and PAGESIZE Fields Information

Bit Field	Bit Value	Bit Description
RSIZE		Defines the number of address lines to be connected to DDR2/3/mDDR memory device
	0	9 row bits
	1h	10 row bits
	2h	11 row bits
	3h	12 row bits
	4h	13 row bits
	5h	14 row bits
	6h	15 row bits
	7h	16 row bits
PAGESIZE		Defines the page size of each page of the external DDR2/3/mDDR memory device
	0	256 words (requires 8 column address bits)
	1h	512 words (requires 9 column address bits)

Copyright © 2011, Texas Instruments Incorporated

Table 7-100. IBANK, RSIZE and PAGESIZE Fields Information (continued)

Bit Field	Bit Value	Bit Description
	2h	1024 words (requires 10 column address bits)
	3h	2048 words (requires 11 column address bits)
IBANK		Defines the number of internal banks on the external DDR2/3/mDDR memory device
	0	1 bank
	1h	2 banks
	2h	4 banks
	3h	8 banks
EBANK		Defines the number of DDR2/3/mDDR memory controller chip selects
	0	CS0 only
	1h	Reserved

When addressing SDRAM, if the REG_IBANK_POS field in the SDRAM Config register is set to 0, and the REG_EBANK_POS field in the SDRAM Config 2 register is also set to 0, the DDR2/3/mDDR memory controller uses the three fields, IBANK, EBANK and PAGESIZE in the SDRAM Config register to determine the mapping from source address to SDRAM row, column, bank, and chip select. If the REG_IBANK_POS field in the SDRAM Config register is set to 1, 2, or 3, or the REG_EBANK_POS field in the SDRAM Config 2 register is set to 1, the DDR2/3/mDDR memory controller uses the 4 fields - IBANK, EBANK, PAGESIZE, and ROWSIZE in the SDRAM Config register to determine the mapping from source address to SDRAM row, column, bank, and chip select. In all cases the DDR2/3/mDDR memory controller considers its SDRAM address space to be a single logical block regardless of the number of physical devices or whether the devices are mapped across 1 or 2 DDR2/3/mDDR memory controller chip selects.

7.3.3.4.1 Address Mapping when REG_IBANK_POS=0 and REG_EBANK_POS=0

For REG_IBANK_POS=0 and REG_EBANK_POS=0, the effect of address mapping scheme is that as the source address increments across DDR2/3/mDDR memory device page boundaries, the DDR2/3/mDDR controller moves onto the same page in the next bank in the current device DDR_CSn[0]. This movement along the banks of the current proceeds to the same page in the next device(if EBANK=1, DDR_CSn[1]) and proceeds through the same page in all its banks before moving over to the next page in the first device(DDR_CSn[0]). The DDR2/3/mDDR controller exploits this traversal across internal banks and chip selects while remaining on the same page to maximize the number of open DDR2/3/mDDR memory device banks within the overall DDR2/3/mDDR memory device space.

Thus, the DDR2/3/mDDR controller can keep a maximum of 16 banks (8 internal banks across 2 chip selects) open at a time, and can interleave among all of them.

Table 7-101. OCP Address to DDR2/3/mDDR Address Mapping for REG_IBANK_POS=0 and REG_EBANK_POS=0

Logical Address			
Row Address	**Chip Select**	**Bank Address**	**Column Address**
	# of bits defined by EBANK of SDRCR	# of bits defined by IBANK of SDRCR	# of bits defined by PAGESIZE of SDRCR
15 bits	EBANK=0 => 0 bits	IBANK=0 => 0 bits	PAGESIZE=0 => 8 bits
	EBANK=1 => 1 bit	IBANK=1 => 1 bit	PAGESIZE=1 => 9 bits
		IBANK=2 => 2 bits	PAGESIZE=2 => 10 bits
		IBANK=3 => 3 bits	PAGESIZE=3 => 11 bits

7.3.3.4.2 Address Mapping when REG_IBANK_POS = 1 and REG_EBANK_POS = 0

For REG_IBANK_POS = 1 and REG_EBANK_POS = 0, the interleaving of banks within a device (per chip select) is limited to 4 banks. However, it can still interleave banks between the two chip selects. Thus, the DDR2/3/mDDR controller can keep a maximum of 16 banks (8 internal banks across 2 chip selects) open at a time, but can only interleave among eight of them.

Table 7-102. OCP Address to DDR2/3/mDDR Address Mapping for REG_IBANK_POS=1 and REG_EBANK_POS=0

Logical Address				
Bank Address[2]	**Row Address**	**Chip Select**	**Bank Address[1:0]**	**Column Address**
# of bits defined by IBANK of SDRCR	# of bits defined by RSIZE of SDRCR	# of bits defined by EBANK of SDRCR	# of bits defined by IBANK of SDRCR	# of bits defined by PAGESIZE of SDRCR

	RSIZE=6 => 15 bits			
	RSIZE=7 => 16 bits			

7.3.3.4.3 Address Mapping when REG_IBANK_POS=2 and REG_EBANK_POS = 0

For REG_IBANK_POS=2 and REG_EBANK_POS = 0, the interleaving of banks within a device (per chip select) is limited to 2 banks. However, it can still interleave banks between the two chip selects. Thus, the DDR2/3/mDDR controller can keep a maximum of 16 banks (eight internal banks across 2 chip selects) open at a time, but can only interleave among four of them.

Table 7-103. OCP Address to DDR2/3/mDDR Address Mapping for REG_IBANK_POS=2 and REG_EBANK_POS=0

		RSIZE=6 => 15 bits	
		RSIZE=7 => 16 bits	

Since the DDR2/3/mDDR memory controller interleaves among less number of banks when IBANK_POS!= 0 or EBANK_POS= 1, these cases are lower in performance than the IBANK_POS= 0 case. Thus these cases are only recommended to be used along with partial array self-refresh where performance can be traded off for power savings.

7.3.3.5 Performance Management

7.3.3.5.1 Command Ordering and Scheduling

The DDR2/3/mDDR memory controller performs command re-ordering and scheduling in an attempt to achieve efficient transfers with maximum throughput. The goal is to maximize the utilization of the data, address, and command buses while hiding the overhead of opening and closing DDR2/3/mDDR SDRAM rows. Command re-ordering takes place within the command FIFO.

The DDR2/3/mDDR memory controller examines all the commands stored in the command FIFO to schedule commands to the external memory. All commands from same master will complete in order, regardless of the master priority. The memory controller does not guarantee ordering between commands from different masters. However, the memory controller will maintain data coherency. Therefore, the memory controller will block a command, regardless of master priority, if that command is to the same block address (2048 bytes) as an older command. Thus, the memory controller might have one or more pending read or write for each master. Among all pending reads, the memory controller selects all reads that have their corresponding SDRAM banks already open. Similarly, among all pending writes, the memory controller selects all writes that have their corresponding SDRAM banks already open.

As a result of the above reordering, at any point of time the memory controller might have several pending reads and writes that have their corresponding banks open. The memory controller then selects the highest priority read from pending reads, and the highest priority write from pending writes. If two or more commands have the highest priority, the memory controller selects the oldest command. As a result, the memory controller might now have a final read and a final write command. The memory controller will pick either the read or the write command depending on the value programmed in the Read Write Execution Threshold register. The memory controller will keep executing reads until the read threshold is met and then switch to executing writes. The memory controller will then keep executing writes until the write threshold is met and then switch back to executing reads. The memory controller will satisfy meeting the threshold values only if that type of command is available for execution, otherwise it will switch to the other type. Similarly, the memory controller will satisfy meeting the threshold value only if the FIFOs for that type have space (Read Data FIFO for reads and Write Status FIFO for writes), otherwise it will switch to the other type.

The memory controller completes executing an OCP command before it switches to another command.

All the accesses to an SDRAM are pipe-lined to maximize the external bus utilization. In other words accesses to an SDRAM are issued back to back such that there are minimum idle cycles between any two accesses. This includes the scheduling listed above to minimize the overhead of opening and closing of SDRAM banks. All of these is done while fulfilling the access timing requirements of an SDRAM.

Besides commands received from on-chip resources, the DDR2/3/mDDR memory controller also issues refresh commands. The DDR2/3/mDDR memory controller attempts to delay refresh commands as long as possible to maximize performance while meeting the SDRAM refresh requirements. As the DDR2/3/mDDR memory controller issues read, write, and refresh commands to DDR2/3/mDDR SDRAM device, it follows the following priority scheme:

1. (Highest priority) SDRAM refresh request due to Refresh Must level of refresh urgency reached (Refer Section Refresh Scheduling)

Copyright © 2011, Texas Instruments Incorporated

2. Request for a read or a write.
3. SDRAM Activate commands.
4. SDRAM Deactivate commands.
5. SDRAM Deep Power-Down request.
6. SDRAM clock stop or Power-Down request.
7. SDRAM refresh request due to Refresh May or Release level of refresh urgency reached (Refer Section Refresh Scheduling)
8. (Lowest priority) SDRAM self-refresh request.

7.3.3.5.2 Command Starvation

The reordering and scheduling rules listed above may lead to command starvation, which is the prevention of certain commands from being processed by the DDR2/3/mDDR memory controller. Command starvation results from the following conditions:

- A continuous stream of high-priority read commands can block a low-priority write command
- A continuous stream of DDR2/3/mDDR SDRAM commands to a row in an open bank can block commands to the closed row in the same bank.

To avoid these conditions, the DDR2/3/mDDR memory controller can momentarily raise the priority of the oldest command in the command FIFO after a set number of transfers have been made. The REG_COS_COUNT_1,REG_COS_COUNT_2 field in the Peripheral Bus Burst Priority Register (PBBPR) sets the number of the transfers that must be made before the DDR2/3/mDDR memory controller will raise the priority of the oldest command. See Class of Service(COS) section for more details.

NOTE: Leaving the REG_COS bits at their default value (FFh) in PBBPR register disables this feature of the DDR2/3/mDDR memory controller. This means commands can stay in the command FIFO indefinitely. Therefore, these bits should be set to FEh immediately following reset to enable this feature with the highest level of allowable memory transfers. It is suggested that system-level prioritization be set to avoid placing high-bandwidth masters on the highest priority levels. These bits can be left as FEh unless advanced bandwidth/prioritization control is required.

7.3.3.5.3 Possible Race Condition

A race condition may exist when certain masters write data to the DDR2/3/mDDR memory controller. For example, if master A passes a software message via a buffer in DDR2/3/mDDR memory and does not wait for indication that the write completes, when master B attempts to read the software message it may read stale data and therefore receive an incorrect message. In order to confirm that a write from master A has landed before a read from master B is performed, master A must wait for the write completion status from the DDR2/3/mDDR memory controller before indicating to master B that the data is ready to be read. If master A does not wait for indication that a write is complete, it must perform the following workaround:

1. Perform the required write.
2. Perform a dummy write to the DDR2 memory controller module ID and revision register.
3. Perform a dummy read to the DDR2 memory controller module ID and revision register.
4. Indicate to master B that the data is ready to be read after completion of the read in step 3.

The completion of the read in step 3 ensures that the previous write was done.

For a list of the master peripherals that need this workaround, see the device-specific data sheet.

7.3.3.5.4 Class of Service (COS)

The commands in the Command FIFO can be mapped to 2 classes of service namely 1 and 2. The mapping of commands to a particular class of service can be done based on the priority or the connection ID.

Copyright © 2011, Texas Instruments Incorporated

The mapping based on priority can be done by setting the appropriate values in the Priority to Class of Service Mapping register (PRI_COS_MAP).

The mapping based on connection ID can be done by setting the appropriate values of connection ID and the masks in the Connection ID to Class of Service Mapping registers(CONNID_COS_1_MAP and CONNID_COS_2_MAP).

There are 3 connection ID and mask values that can be set for each class of service. In conjunction with the masks, each class of service can have a maximum of 144 connection IDs mapped to it. For example, a connection ID value of 0xFF along with a mask value of 0x3 will map all connection IDs from 0xF8 to 0xFF to that particular class of service.

Each class of service has an associated latency counter (REG_COS_COUNT). The value of this counter can be set in the Peripheral Bus Burst Priority Register (PBBPR). When the latency counter for a command expires, i.e., reaches the value programmed for the class of service that the command belongs to, that command will be the one that is executed next. If there are more than one commands that have expired latency counters, the command with the highest priority will be executed first. One exception to this rule is, if the oldest command in the queue has an expired reg_pr_old_count, that command will be executed first irrespective of priority or class of service. This is done to prevent a continuous block effect.

The connection ID mapping allows the same connection ID to be put in both class of service 1 and 2. Also, a transaction might belong to one class of service if viewed by connection ID and might belong to another class of service if viewed by priority. In these cases, the command will belong to both class of service. The DDR2/3/mDDR memory controller will try executing the command as soon as possible, when the smaller of the two counters (REG_COS_COUNT_1 OR REG_COS_COUNT_2) expire.

7.3.3.5.5 Refresh Scheduling

The DDR2/3/mDDR memory controller issues autorefresh (REFR) commands to DDR2/3/mDDR SDRAM devices at a rate defined in the refresh rate (REFRESH_RATE) bit field in the SDRAM refresh control register (SDRFC). A refresh interval counter is loaded with the value of the REFRESH_RATE bit field and decrements by 1 each cycle until it reaches zero. Once the interval counter reaches zero, it reloads with the value of the REFRESH_RATE bit. Each time the interval counter expires, a refresh backlog counter increments by 1. Conversely, each time the DDR2/3/mDDR memory controller performs a REFR command, the backlog counter decrements by 1. This means the refresh backlog counter records the number of REFR commands the DDR2/3/mDDR memory controller currently has outstanding.

The DDR2/3/mDDR memory controller issues REFR commands based on the level of urgency. The level of urgency is defined below. Whenever the refresh level of urgency is reached, the DDR2/3/mDDR memory controller issues a REFR command before servicing any new memory access requests. Following a REFR command, the DDR2/3/mDDR memory controller waits T_RFC cycles, defined in the SDRAM timing 1 register (SDRTIM1), before rechecking the refresh urgency level.

The refresh counters do not operate when the SDRAM memory is in self-refresh mode.

Table 7-109. Refresh Modes

Urgency Level	Description
Refresh May	Backlog count is greater than 0. Indicates there is a backlog of REFR commands, when the DDR2/3/mDDR memory controller is not busy it will issue the REFR command.
Refresh Release	Backlog count is greater than 4. Indicates that the refresh backlog of REFR commands is getting high and when DDR2/3/mDDR memory controller is not busy it should issue the REFR command.
Refresh Must	Backlog count is greater than 7. Indicates that the refresh backlog of REFR commands is getting excessive and DDR2/3/mDDR memory controller should perform an auto refresh cycle before servicing any new memory access requests.

Copyright © 2011, Texas Instruments Incorporated

The DDR2/3/mDDR memory controller starts servicing new memory accesses after Refresh Release level is cleared. If any of the commands in the Command FIFO have class of service latency counters that are expired, the DDR2/3/mDDR memory controller will not wait for Refresh Release level to be cleared but will only perform one refresh command and exit the refresh state.

7.3.3.6 DDR3 Read-Write Leveling

The DDR2/3/mDDR memory controller supports read-write leveling in conjunction with the DDR PHY. The DDR2/3/mDDR memory controller supports two types of write/read leveling:

1. Full leveling
2. Incremental leveling

NOTE: Please refer the device specific data sheet to know the type of leveling supported.

Each leveling type has three parts:

1. Write leveling
2. Read DQS gate training
3. Read data eye training

Read and write leveling is only supported to DDR3 memory.

The DDR2/3/mDDR memory controller does not perform full leveling after initialization upon reset deassertion. Full leveling must be triggered by software after the DDR2/3/mDDR memory controller registers are properly configured. The DDR2/3/mDDR memory controller supports triggering of full leveling through software through the use of the REG_RDWRLVLFULL_START field in the Read-Write Leveling Control register(RWLCR). Since full leveling takes considerable amount of time and refreshes cannot be issued to DDR3 when DDR3 is put in leveling mode, refresh interval will be violated and data inside DDR3 can be lost. Although, this is not an issue at power-up, this might be an issue if full leveling is triggered when DDR3 is functional.

The memory controller supports incremental leveling to better track voltage and temperature changes during normal operation. The incremental leveling can be enabled by writing a non-zero value to the REG_WRLVLINC_INT, REG_RDLVLGATEINC_INT, and REG_RDLVLINC_INT fields in the Read-Write Leveling Control register(RWLCR). The memory controller periodically triggers incremental write leveling every time REG_WRLVLINC_INT expires. In other words, the REG_WRLVLINC_INT defines the interval between successive incremental write leveling.

Similarly, the memory controller periodically triggers incremental read DQS gate training every time REG_RDLVLGATEINC_INT expires, and triggers incremental read data eye training every time REG_RDLVLINC_INT expires.

To minimize impact on bandwidth, the software can program these intervals such that these three intervals do not expire at same time. The value of interval programmed is dependent on the slope of voltage and temperature changes.

The memory controller supports increasing the rate of incremental leveling automatically for a defined period of time. This can be achieved by programming the Read-Write Leveling Ramp Window register(RDWR_LVL_RMP_WIN) and the Read-Write Leveling Ramp Control register(RDWR_LVL_RMP_CTRL). Whenever a pulse is received, the memory controller would use the intervals programmed in the Read-Write Leveling Ramp Control register until the REG_RDWRLVLINC_RMP_WIN in the Read-Write Leveling Ramp Window register expires. After the expiration of REG_RDWRLVLINC_RMP_WIN the memory controller switches back to use the intervals programmed in the Read-Write Leveling Control register.

To guarantee none of the incremental leveling events are missed, the REG_RDWRLVLINC_RMP_WIN must be programmed greater than the intervals in the Read-Write Leveling Ramp Control register.

If the memory controller is in Self-Refresh or Power-Down modes when any of the incremental leveling intervals expire, the memory controller will exit Self-Refresh or Power-Down mode, perform the required leveling, and then re-enter the Self-Refresh or Power-Down mode. The memory controller also triggers incremental leveling on Self-Refresh exit.

Copyright © 2011, Texas Instruments Incorporated

7.3.3.7 PRCM Sequence for DDR2/3/mDDR Memory controller

The memory controller clock, reset and power are handled by the device PRCM module. Refer to the Power Reset Clock Management (PRCM) chapter for the PRCM register details.

7.3.3.8 Interrupt Support

The DDR2/3/mDDR controller is compliant with Open Core Protocol Specification (OCP-IP 2.2). The controller supports only Idle, Write, Read, and WriteNonPost command types. Also, the controller supports only incrementing, wrapping, and 2-dimensional block addressing modes. The controller supports generation of an error interrupt if an unsupported command or a command with unsupported addressing mode is received.

7.3.3.9 EDMA Event Support

The DDR2/3/mDDR memory controller is a DMA slave peripheral and therefore does not generate EDMA events. Data read and write requests may be made directly by masters including the EDMA controller.

7.3.3.10 Emulation Considerations

The DDR2/3/mDDR memory controller will remain fully functional during emulation halts to allow emulation access to external memory.

7.3.3.11 Power Management

This section defines the power management capabilities and requirements.

7.3.3.11.1 Clock Stop Mode

The memory controller supports Clock Stop mode for LPDDR1/mDDR. The memory controller automatically stops the clocks to the memory, after the memory controller is idle for REG_CS_TIM number of DDR clock cycles and the REG_LP_MODE field is set to 1. The REG_LP_MODE and REG_CS_TIM fields can be programmed in the power management control register (PMCR).

When the clock to the memory is stopped, the memory controller services register accesses as normal. If an SDRAM access is requested, or the Refresh Must level is reached while in the Clock Stop mode, the memory controller will start the clocks. The memory controller now can issue any commands. If the power saving mode is changed by changing REG_LP_MODE from 1 to some other value, the memory controller will exit Clock Stop mode and enter the new power saving mode.

7.3.3.11.2 Self-Refresh Mode

The DDR2/3/mDDR memory controller supports self-refresh mode for low power. The memory controller automatically puts the SDRAM into self-refresh after the memory controller is idle for REG_SR_TIM number of DDR clock cycles and the REG_LP_MODE field is set to 2. The REG_LP_MODE and REG_SR_TIM fields can be programmed in the Power Management Control register(PMCR). The memory controller will complete all pending refreshes before it puts the SDRAM into self-refresh. Therefore, after the expiration of REG_SR_TIM, the memory controller will start issuing refreshes to complete the refresh backlog, and then issue a SELF-REFRESH command to the SDRAM.

In self-refresh mode, the memory controller automatically stops the clocks DDR_CLK to the SDRAM. The memory controller maintains DDR_CKE low to maintain the self-refresh state. When the SDRAM is in self-refresh, the memory controller services register accesses as normal. If the REG_LP_MODE field is set not equal to 2, or an SDRAM access is requested while it is in self-refresh, and T_CKE + 1 cycles have elapsed since the SELF-REFRESH command was issued, the memory controller will bring the SDRAM out of self-refresh. The value of T_CKE is taken from SDRAM Timing 2 register. For DDR3, memory controller will also exit self-refresh to perform incremental leveling.

Exit sequence of self-refresh mode for LPDDR1 device: The memory controller:

- Enables clocks.
- Drives DDR_CKE high.

Copyright © 2011, Texas Instruments Incorporated

- Waits for T_XSNR + 1 cycles. The value of T_XSNR is taken from SDRAM Timing 2 register.
- Starts an auto-refresh cycle in the next cycle.
- Enters its idle state and can issue any commands.

Exit sequence of self-refresh mode for DDR2 device: The memory controller:

- Enables clocks.
- Drives DDR_CKE high.
- Waits for T_XSNR + 1 cycles. The value of T_XSNR is taken from SDRAM Timing 2 register.
- If the REG_DDR_DISABLE_DLL bit in the SDRAM Config register is 1, issues a LOAD MODE REGISTER command to the extended mode register 1 with the pad_a_o bits set as follows:

Bits	Value	Description
DDR_A[15:13]	0x0	!reg_ddr2_ddqs
DDR_A[12]	0x0	Output buffer enabled
DDR_A[11]	0x0	RDQS disable
DDR_A[10]	!reg_ddr2_ddqs	Differential DQS enable value from SDRAM Config register
DDR_A[9:7]	0x0	Exit OCD calibration mode
DDR_A[6]	reg_ddr_term[1]	DDR2 termination resistor value from SDRAM Config register
DDR_A[5:3]	0x0	Additive latency = 0
DDR_A[2]	reg_ddr_term[0]	DDR2 termination resistor value from SDRAM Config register
DDR_A[1]	reg_sdram_drive	SDRAM drive strength from SDRAM Config register
DDR_A[0]	0x1	Disable DLL

- Starts an auto-refresh cycle in the next cycle.
- Enters its idle state and can issue any other commands except a write or a read. A write or a read will only be issued after T_XSRD + 1 clock cycles have elapsed since DDR_CKE is driven high. The value of T_XSRD is taken from SDRAM Timing 2 register.

Exit sequence of self-refresh mode for DDR3 device: The memory controller:

- Enables clocks.
- Drives DDR_CKE high.
- Waits for T_XSNR + 1 cycles. The value of T_XSNR is taken from SDRAM Timing 2 register.
- If the REG_DDR_DISABLE_DLL bit in the SDRAM Config register is 1, issues a LOAD MODE REGISTER command to the extended mode register 1 with the pad_a_o bits set as follows:

Bits	Value	Description
DDR_A[15:13]	0x0	Reserved
DDR_A[12]	0x0	Output buffer enabled
DDR_A[11]	0x0	TDQS disable
DDR_A[10]	0x0	Reserved
DDR_A[9]	reg_ddr_term[2]	DDR3 termination resistor value from SDRAM Config register
DDR_A[8]	0x0	Reserved
DDR_A[7]	0x0	Write leveling disabled
DDR_A[6]	reg_ddr_term[1]	DDR3 termination resistor value from SDRAM Config register
DDR_A[5]	reg_sdram_drive[1]	SDRAM drive strength from SDRAM Config register
DDR_A[4:3]	0x0	Additive latency = 0
DDR_A[2]	reg_ddr_term[0]	DDR3 termination resistor value from SDRAM Config register
DDR_A[1]	reg_sdram_drive[0]	SDRAM drive strength from SDRAM Config register
DDR_A[0]	0x1	Disable DLL

Copyright © 2011, Texas Instruments Incorporated

- Starts an auto-refresh cycle in the next cycle.
- Performs one write incremental leveling.
- Performs read DQS incremental training.
- Performs read data-eye incremental training.
- Enters its idle state and can issue any other commands except a write or a read. A write or a read will only be issued after T_XSRD + 1 clock cycles have elapsed since DDR_CKE is driven high. The value of T_XSRD is taken from SDRAM Timing 2 register.

7.3.3.11.3 Power Down Mode

The memory controller also supports power-down mode for low power. The memory controller automatically puts the SDRAM into power-sDown after the memory controller is idle for REG_PD_TIM number of DDR clock cycles and the REG_LP_MODE field is set to 4. The REG_LP_MODE and REG_PD_TIM fields can be programmed in the Power Management Control register (PMCR). If the Refresh Must level is not reached before the entry into power-down, the memory controller will not precharge all banks before issuing the POWER-DOWN command. This will result in SDRAM entering active power-down mode.

If the Refresh Must level is reached before the entry into power-down, the memory controller will precharge all banks and issue refreshes until the Refresh Release Level is reached before issuing the POWER-DOWN command. This will result in SDRAM entering precharge power-down mode.

In power-down mode, the memory controller does not stop the clocks DDR_CLK to the SDRAM. The memory controller maintains DDR_CKE low to maintain the power-down state.

When the SDRAM is in power-down, the memory controller services register accesses as normal. If the REG_LP_MODE field is set not equal to 4, or an SDRAM access is requested, or the Refresh Must level is reached while the SDRAM is in power-down, the memory controller will bring the SDRAM out of power-down. For DDR3, memory controller will also exit power-down to perform incremental leveling.

Exit sequence of power-down mode for DDR2, DDR3 and LPDDR1: The memory controller

- Drives DDR_CKE high after T_CKE + 1 cycles have elapsed since the POWER-DOWN command was issued. The value of T_CKE is taken from SDRAM Timing 2 register.
- Waits for T_XP + 1 cycles. The value of T_XP is taken from SDRAM Timing 2 register.
- Enters its idle state and can issue any commands.

7.3.3.11.4 Deep Power-Down Mode

For ultimate power savings, the memory controller supports deep power-down mode for LPDDR1.

The SDRAM can be forced into deep power-down through software by setting the reg_dpd_en field in the Power Management Control register to 1. In this case, the memory controller will continue normal operation until all SDRAM memory access requests have been serviced. At this point the memory controller will issue a DEEP POWER-DOWN command. The memory controller then maintains pad_cke_o low to maintain the Deep Power-Down state. In deep power-down mode, the memory controller automatically stops the clocks to the SDRAM.

Setting the REG_DPD_EN field to 1 overrides the setting of REG_LP_MODE field. Therefore, if the SDRAM is in Clock Stop, Self Refresh, or Power-Down mode, and REG_DPD_EN field is set to 1, the memory controller will exit those modes and go into deep power-down mode.

When the SDRAM is in deep power-down, the memory controller services register accesses as normal.

If the REG_DPD_EN field is set to 0, or an SDRAM access is requested, the memory controller will bring the SDRAM out of deep power-down.

Exit sequence for LPDDR1: The memory controller:

- Performs SDRAM initialization as specified in the LPDDR1(mDDR) SDRAM Memory Initialization section.
- Enters its idle state and can issue any commands.

Copyright © 2011, Texas Instruments Incorporated

Since the memory controller performs initialization upon deep power-down exit, the REG_REFRESH_RATE field in the SDRAM Refresh Control register must be set appropriately to meet the 200µs wait requirement for LPDDR1.

7.3.3.11.5 Save and Restore Mode

The DDR2/3/mDDR memory controller supports save and restore mechanism to completely switch off power to the DDR2/3/mDDR memory controller. The following sequence of operations is followed to put DDR2/3/mDDR memory controller in off mode:

An external master reads the following memory mapped registers and saves their value external to the DDR2/3/mDDR memory controller.

1. SDRAM Config register (SDRCR)
2. SDRAM Config 2 register
3. SDRAM Refresh Control register (SDRRCR)
4. SDRAM Refresh Control Shadow register (SDRRCSR)
5. SDRAM Timing 1 register (SDRTIM1)
6. SDRAM Timing 1 Shadow register (SDRTIM1SR)
7. SDRAM Timing 2 register (SDRTIM2)
8. SDRAM Timing 2 Shadow register (SDRTIM2SR)
9. SDRAM Timing 3 register (SDRTIM3)
10. SDRAM Timing 3 Shadow register (SDRTIM3SR)
11. Power Management Control register (PMCR)
12. Power Management Control Shadow register (PMCSR)
13. Peripheral Bus Burst Priority Register (PBBPR)
14. System OCP Interrupt Enable Set Register (SOIESR)
15. DDR PHY Control 1 register (DDRPHYCR)
16. DDR PHY Control 1 Shadow register (DDRPHYCSR)

- Memory controller completes all pending transactions and drains all its FIFOs.
- Memory controller puts the SDRAM in Self Refresh.
- Memory controller copies all shadow memory mapped registers to its main registers. It is assumed that the shadow register always has the same value as its corresponding main register.
- Memory controller waits for all interrupts to be serviced.
- Memory controller acknowledges assertion of internal power down request.
- The internal module reset signal is asserted.
- The clocks and power to the memory controller can now be switched off.

To restore power to the memory controller, the following sequence of operations is followed:

- The power and clocks to the Memory controller are switched on.
- The internal module reset signal is deasserted, indicating to the Memory controller that it is waking up from off mode.
- The memory controller does not perform SDRAM initialization and forces its state machine to be in self-refresh.
- The external master restores all of the above memory mapped registers.
- The external master restores all of the above memory mapped registers.
- The system can now perform access to the external memory.

7.3.3.11.6 EMIF PHY Clock Gating

The clock to the DDR2/3/mDDR PHY can be gated off to achieve power saving. Refer to the EMIF0/1 Clock Gate Control register (EMIF_CLK_GATE).

Copyright © 2011, Texas Instruments Incorporated

7.3.4 Use Cases

For details on connecting this device to mDDR/DDR2/DDR3 devices, see the device-specific data sheet, which will include specific instructions and routing guidelines for interfacing to mDDR (LPDDR), DDR2, and DDR3 devices.

7.3.5 EMIF4D Registers

Table 7-110 lists the memory-mapped registers for the EMIF4D. All other register offset addresses not listed in Table 7-110 should be considered as reserved locations and the register contents should not be modified.

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 7-113. SDRAM_CONFIG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-29	reg_sdram_type	R/W	0h	SDRAM Type selection. Set to 0 for DDR1, set to 1 for LPDDR1, set to 2 for DDR2, set to 3 for DDR3, and set to 4 for LPDDR2. All other values are reserved.
28-27	reg_ibank_pos	R/W	0h	Internal bank position. Set to 0 to assign internal bank address bits from lower OCP address bits as shown in tables. Set to 1, 2, or 3 to assign internal bank address bits from higher OCP address as shown in tables.
26-24	reg_ddr_term	R/W	0h	DDR2 and DDR3 termination resistor value. Set to 0 to disable termination. For DDR2, set to 1 for 75 ohm, set to 2 for 150 ohm, and set to 3 for 50 ohm. For DDR3, set to 1 for RZQ/4, set to 2 for RZQ/2, set to 3 for RZQ/6, set to 4 for RZQ/12, and set to 5 for RZQ/8. All other values are reserved.
23	reg_ddr2_ddqs	R/W	0h	DDR2 and LPDDR2 differential DQS enable. Set to 0 for single ended DQS. Set to 1 for differential DQS.
22-21	reg_dyn_odt	R/W	0h	DDR3 Dynamic ODT. Set to 0 to turn off dynamic ODT. Set to 1 for RZQ/4 and set to 2 for RZQ/2. All other values are reserved.
20	reg_ddr_disable_dll	R/W	0h	Disable DLL select. Set to 1 to disable DLL inside SDRAM.
19-18	reg_sdram_drive	R/W	0h	SDRAM drive strength. For DDR1/DDR2, set to 0 for normal, and set to 1 for weak drive strength. For DDR3, set to 0 for RZQ/6 and set to 1 for RZQ/7. For LPDDR1, set to 0 for full, set to 1 for 1/2, set to 2 for 1/4, and set to 3 for 1/8 drive strength. All other values are reserved.
17-16	reg_cwl	R/W	0h	DDR3 CAS Write latency. Value of 0, 1, 2, and 3 (CAS write latency of 5, 6, 7, and 8) are supported. Use the lowest value supported for best performance. All other values are reserved.

Copyright © 2011, Texas Instruments Incorporated

Table 7-113. SDRAM_CONFIG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
15-14	reg_narrow_mode	R/W	0h	SDRAM data bus width. Set to 0 for 32-bit and set to 1 for 16-bit. All other values are reserved.
13-10	reg_cl	R/W	0h	CAS Latency. The value of this field defines the CAS latency to be used when accessing connected SDRAM devices. Value of 2, 3, 5, and 6 (CAS latency of 2, 3, 1.5, and 2.5) are supported for DDR1. Value of 2, 3, 4, and 5 (CAS latency of 2, 3, 4, and 5) are supported for DDR2. Value of 2, 4, 6, 8, 10, 12, and 14 (CAS latency of 5, 6, 7, 8, 9, 10, and 11) are supported for DDR3. Value of 2 and 3 (CAS latency of 2 and 3) are supported for LPDDR1. Value of 3, 4, 5, 6, 7, and 8 (CAS latency of 3, 4, 5, 6, 7, and 8) are supported for LPDDR2-SDRAM. All other values are reserved.
9-7	reg_rowsize	R/W	0h	Row Size. Defines the number of row address bits of connected SDRAM devices. Set to 0 for 9 row bits, set to 1 for 10 row bits, set to 2 for 11 row bits, set to 3 for 12 row bits, set to 4 for 13 row bits, set to 5 for 14 row bits, set to 6 for 15 row bits, and set to 7 for 16 row bits. This field is only used when reg_ibank_pos field in SDRAM Config register is set to 1, 2, or 3, or reg_ebank_pos field in SDRAM Config_2 register is set to 1.
6-4	reg_ibank	R/W	0h	Internal Bank setup. Defines number of banks inside connected SDRAM devices. Set to 0 for 1 bank, set to 1 for 2 banks, set to 2 for 4 banks, and set to 3 for 8 banks. All other values are reserved.
3	reg_ebank	R/W	0h	External chip select setup. Defines whether SDRAM accesses will use 1 or 2 chip select lines. Set to 0 to use pad_cs_o_n[0] only. All other values reserved. This bit will automaticlly be set to 0 if reg_cs1nvmen field in the LPDDR2-NVM is set to 1.
2-0	reg_pagesize	R/W	0h	Page Size. Defines the internal page size of connected SDRAM devices. Set to 0 for 256-word page (8 column bits), set to 1 for 512-word page (9 column bits), set to 2 for 1024-word page (10 column bits), and set to 3 for 2048-word page (11 column bits). All other values are reserved.

15	14	13	12	11	10	9	8
reg_refresh_rate							
R/W-0h							
7	6	5	4	3	2	1	0
reg_refresh_rate							
R/W-0h							

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 7-115. SDRAM_REF_CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31	reg_initref_dis	R/W	0h	Initialization and Refresh disable. When set to 1, EMIF will disable SDRAM initialization and refreshes, but will carry out SDRAM write/read transactions.
30	Reserved	R	XXXh	
29	reg_srt	R/W	0h	DDR3 Self Refresh temperature range. Set to 0 for normal operating temperature range and set to 1 for extended operating temperature range when the reg_asr field is set to 0. This bit must be set to 0 if the reg_asr field is set to 1. A write to this field will cause the EMIF to start the SDRAM initialization sequence.
28	reg_asr	R/W	0h	DDR3 Auto Self Refresh enable. Set to 1 for auto Self Refresh enable. Set to 0 for manual Self Refresh reference indicated by the reg_srt field. A write to this field will cause the EMIF to start the SDRAM initialization sequence.
27	Reserved	R	XXXh	
26-24	reg_pasr	R/W	0h	Partial Array Self Refresh. These bits get loaded into the Extended Mode Register of an LPDDR1 or DDR3 during initialization. For LPDDR1, set to 0 for full array, set to 1 for 1/2 array, set to 2 for 1/4 array, set to 5 for 1/8 array, and set to 6 for 1/16 array to be refreshed. For DDR3, set to 0 for full array, set to 1 or 5 for 1/2 array, set to 2 or 6 for 1/4 array, set to 3 or 7 for 1/8 array, and set to 4 for 3/4 array to be refreshed. All other values are reserved. A write to this field will cause the EMIF to start the SDRAM initialization sequence.
23-16	Reserved	R	XXXh	

Copyright © 2011, Texas Instruments Incorporated

Table 7-115. SDRAM_REF_CTRL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
15-0	reg_refresh_rate	R/W	0h	Refresh Rate. Value in this field is used to define the rate at which connected SDRAM devices will be refreshed. SDRAM refresh rate = EMIF rate / reg_refresh_rate where EMIF rate is equal to m_clk rate. If reg_refresh_rate andlt (8*reg_t_rfc)+reg_t_rp+reg_t_rcd+20 then it will be loaded with (8*reg_t_rfc)+reg_t_rp+reg_t_rcd+20. This is done to avoid lock-up situations when illegal values are programmed.

Copyright © 2011, Texas Instruments Incorporated

7.3.5.6 SDRAM_REF_CTRL_SHDW Register (offset = 14h) [reset = 0h]

SDRAM_REF_CTRL_SHDW is shown in Figure 7-96 and described in Table 7-116.

Table 7-132. IODFT_TLGC Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3-1	reg_pc	R/W	0h	Pattern code. Defines the type of pattern that is selected for the pattern generators. Set to 0 for functional mode and set to 4 to hold current register value. For output pattern generator, set to 1 for random XOR, set to 2 for random XNOR, and set to 3 for an 8 bit shifter. For input pattern generator, set to 5 for random XOR, set to 6 for random XNOR, and set to 7 for an 8 bit shifter.
0	reg_tm	R/W	1h	Functional mode enable. Set to 1 for functional mode, and set to 0 for IODFT mode.

Bit	Field	Type	Reset	Description
31-4	reg_ddr_phy_ctrl_1	R/W	0h	This register is used to control the DDR PHY. The bit field definitions are DDR PHY specific and should be described in the DDR PHY specification.
3-0	reg_read_latency	R/W	0h	This field defines the read latency for the read data from SDRAM in number of m_clk cycles. This field is used by the EMIF as well as the PHY. The EMIF will expect the first read data to arrive (reg_read_latency + 3) m_clk cycles from the read command. Refer to the PHY specification for information on programming this field.

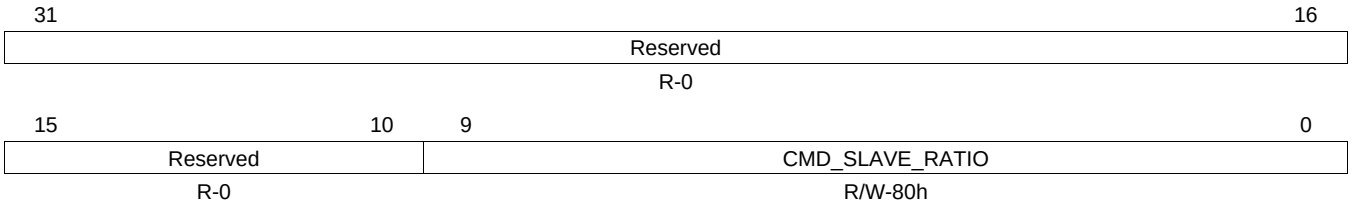
7.3.6.1 DDR PHY Command 0/1/2 Address/Command Slave Ratio Register (CMD0/1/2_REG_PHY_CTRL_SLAVE_RATIO_0)

The DDR PHY Command 0/1/2 Address/Command Slave Ratio Register (CMD0/1/2_REG_PHY_CTRL_SLAVE_RATIO_0) is shown in the figure and table below.

Figure 7-140. DDR PHY Command 0/1/2 Address/Command Slave Ratio Register (CMD0/1/2_REG_PHY_CTRL_SLAVE_RATIO_0)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

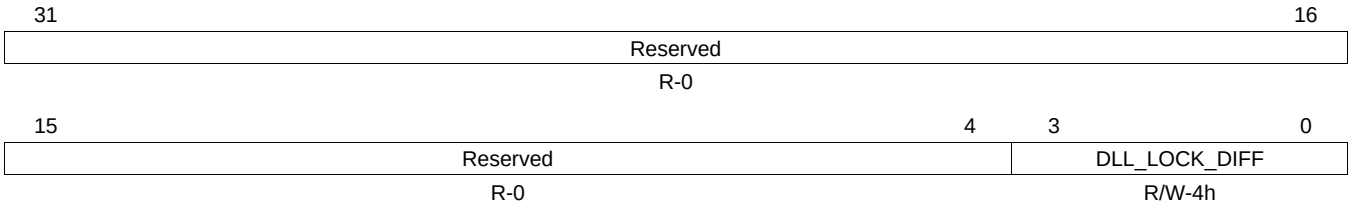
Table 7-161. DDR PHY Command 0/1/2 Address/Command Slave Ratio Register (CMD0/1/2_REG_PHY_CTRL_SLAVE_RATIO_0) Field Descriptions

Bit	Field	Value	Description
31-10	Reserved		Reserved
9-0	CMD_SLAVE_RATIO	0-80h	Ratio value for address/command launch timing in DDR PHY macro. This is the fraction of a clock cycle represented by the shift to be applied to the read DQS in units of 256ths. In other words, the full-cycle tap value from the master DLL will be scaled by this number over 256 to get the delay value for the slave delay line.

7.3.6.2 DDR PHY Command 0/1/2 Address/Command DLL Lock Difference Register(CMD0/1/2_REG_PHY_DLL_LOCK_DIFF_0)

The DDR PHY Command 0/1/2 Address/Command DLL Lock Difference Register (CMD0/1/2_REG_PHY_DLL_LOCK_DIFF_0) is shown in the figure and table below.

Figure 7-141. DDR PHY Command 0/1/2 Address/Command DLL Lock Difference Register(CMD0/1/2_REG_PHY_DLL_LOCK_DIFF_0)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 7-162. DDR PHY Command 0/1/2 Address/Command DLL Lock Difference Register(CMD0/1/2_REG_PHY_DLL_LOCK_DIFF_0) Field Descriptions

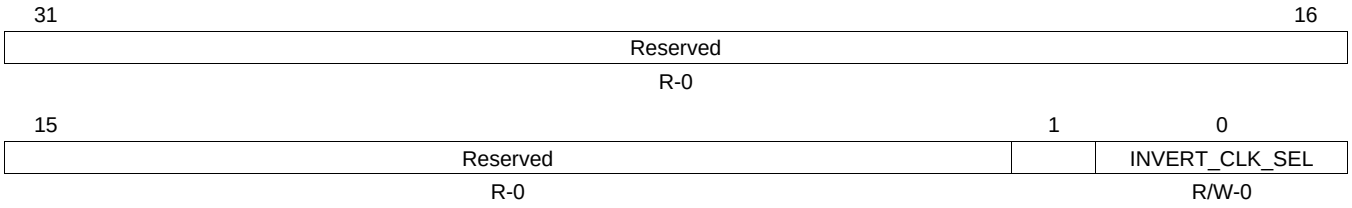
Bit	Field	Value	Description
31-4	Reserved		Reserved
3-0	DLL_LOCK_DIFF	0-4h	The max number of delay line taps variation allowed while maintaining the master DLL lock.This is calculated as total jitter/ delay line tap size, where total jitter is half of (incoming clock jitter (pp) + delay line jitter (pp)).

Copyright © 2011, Texas Instruments Incorporated

7.3.6.3 DDR PHY Command 0/1/2 Invert Clockout Selection Register(CMD0/1/2_REG_PHY_INVERT_CLKOUT_0)

The CDDR PHY Command 0/1/2 Invert Clockout Selection Register(CMD0/1/2_REG_PHY_INVERT_CLKOUT_0) is shown in the figure and table below.

Figure 7-142. DDR PHY Command 0/1/2 Invert Clockout Selection Register(CMD0/1/2_REG_PHY_INVERT_CLKOUT_0)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

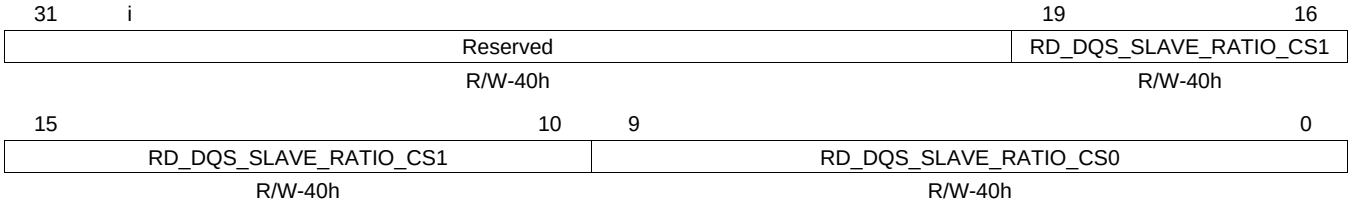
Table 7-163. DDR PHY Command 0/1/2 Invert Clockout Selection Register(CMD0/1/2_REG_PHY_INVERT_CLKOUT_0) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved
0	INVERT_CLK_SEL		Inverts the polarity of DRAM clock.
		0	Core clock is passed on to DRAM
		1	inverted core clock is passed on to DRAM

7.3.6.4 DDR PHY Data Macro 0/1 Read DQS Slave Ratio Register (DATA0/1_REG_PHY_RD_DQS_SLAVE_RATIO_0)

The DDR PHY Data Macro 0/1 Read DQS Slave Ratio Register(DATA0/1_REG_PHY_RD_DQS_SLAVE_RATIO_0) is shown in the figure and table below.

Figure 7-143. DDR PHY Data Macro 0/1 Read DQS Slave Ratio Register (DATA0/1_REG_PHY_RD_DQS_SLAVE_RATIO_0))



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 7-164. DDR PHY Data Macro 0/1 Read DQS Slave Ratio Register (DATA0/1_REG_PHY_RD_DQS_SLAVE_RATIO_0) Field Descriptions

Bit	Field	Value	Description
31-20	Reserved		Reserved
19-10	RD_DQS_SLAVE_RATIO_CS1	40h	Ratio value for Read DQS slave DLL for CS1. This is the fraction of a clock cycle represented by the shift to be applied to the read DQS in units of 256ths. In other words, the full-cycle tap value from the master DLL will be scaled by this number over 256 to get the delay value for the slave delay line.
9-0	RD_DQS_SLAVE_RATIO_CS0	40h	Ratio value for Read DQS slave DLL for CS0. This is the fraction of a clock cycle represented by the shift to be applied to the read DQS in units of 256ths. In other words, the full-cycle tap value from the master DLL will be scaled by this number over 256 to get the delay value for the slave delay line.

7.4 ELM

7.4.1 Introduction

Non-managed NAND flash memories can be dense and nonvolatile in their own nature, but error-prone. When reading from NAND flash memories, some level of error-correction is required. In the case of NAND modules with no internal correction capability, sometimes referred to as bare NANDs, the correction process is delegated to the memory controller.

The general-purpose memory controller (GPMC) probes data read from an external NAND flash and uses this to compute checksum-like information, called syndrome polynomials, on a per-block basis. Each syndrome polynomial gives a status of the read operations for a full block, including 512 bytes of data, parity bits, and an optional spare-area data field, with a maximum block size of 1023 bytes. Computation is based on a Bose-ChaudhurI-Hocquenghem (BCH) algorithm. The error-location module (ELM) extracts error addresses from these syndrome polynomials.

Based on the syndrome polynomial value, the ELM can detect errors, compute the number of errors, and give the location of each error bit. The actual data is not required to complete the error-correction algorithm. Errors can be reported anywhere in the NAND flash block, including in the parity bits.

The maximum acceptable number of errors that can be corrected depends on a programmable configuration parameter. 4-, 8-, and 16-bit error-correction levels are supported. The ELM relies on a static and fixed definition of the generator polynomial for each error-correction level that corresponds to the generator polynomials defined in the GPMC (there are three fixed polynomial for the three correction error levels). A larger number of errors than the programmed error-correction level may be detected, but the ELM cannot correct them all. The offending block is then tagged as uncorrectable in the associated computation exit status register. If the computation is successful, that is, if the number of errors detected does not exceed the maximum value authorized for the chosen correction capability, the exit status register contains the information on the number of detected errors.

When the error-location process completes, an interrupt is triggered to inform the central processing unit (CPU) that its status can be checked. The number of detected errors and their locations in the NAND block can be retrieved from the module through register accesses.

7.4.1.1 ELM Features

The ELM has the following features:

- 4, 8, and 16 bits per 512-byte block error-location based on BCH algorithms
- Eight simultaneous processing contexts
- Page-based and continuous modes
- Interrupt generation on error-location process completion:
  - When the full page has been processed in page mode
  - For each syndrome polynomial in continuous mode

7.4.1.2 Unsupported ELM Features

There are no unsupported ELM features in this device.

Copyright © 2011, Texas Instruments Incorporated

7.4.2 Integration

The error location module (ELM) is used to extract error addresses from syndrome polynomials generated using a BCH algorithm. Each of these polynomials gives a status of the read operations for a 512 bytes block from a NAND flash and its associated BCH parity bits, plus optionally some spare area information.

The ELM is intended to be used in conjunction with the GPMC. Syndrome polynomials generated on-the-fly when reading a NAND Flash page and stored in GPMC registers are passed to the ELM module. The MPU can then easily correct the data block by flipping the bits pointed to by the ELM error locations outputs.

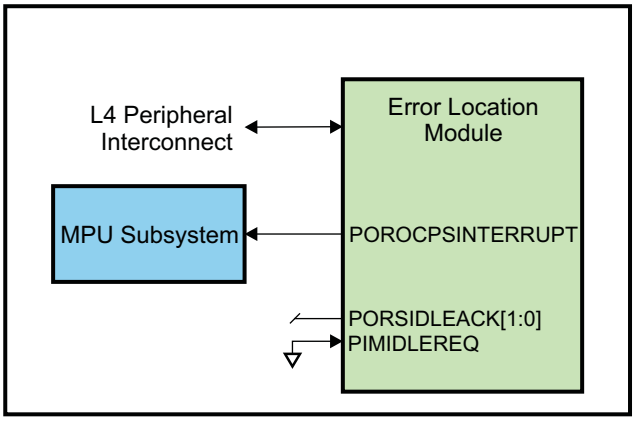

Figure 7-151. ELM Integration

7.4.2.1 ELM Connectivity Attributes

The general connectivity for the ELM module in this device is summarized in Table 7-174.

Table 7-174. ELM Connectivity Attributes

Attributes	Type
Power Domain	Peripheral Domain
Clock Domain	L4PER_L4LS_GCLK
Reset Signals	PER_DOM_RST_N
Idle/Wakeup Signals	Smart Idle
Interrupt Requests	1 interrupt to MPU Subsystem
DMA Requests	None
Physical Address	L4 Peripheral slave port

7.4.2.2 ELM Clock and Reset Management

The ELM operates from a single OCP interface clock.

Table 7-175. ELM Clock Signals

Clock Signal	Max Freq	Reference / Source	Comments
Functional/interface clock	100 MHz	CORE_CLKOUTM4 / 2	pd_per_l4ls_gclk From PRCM

7.4.2.3 ELM Pin List

The ELM module does not include any external interface pins.

Copyright © 2011, Texas Instruments Incorporated

7.4.3 Functional Description

The ELM is designed around the error-location engine, which handles the computation based on the input syndrome polynomials.

The ELM maps the error-location engine to a standard interconnect interface by using a set of registers to control inputs and outputs.

7.4.3.1 ELM Software Reset

To perform a software reset, write a 1 to the ELM_SYSCONFIG[1] SOFTRESET bit. The ELM_SYSSTATUS[0] RESETDONE bit indicates that the software reset is complete when its value is 1. When the software reset completes, the ELM_SYSCONFIG[1] SOFTRESET bit is automatically reset.

7.4.3.2 ELM Power Management

Table 7-176 describes the power-management features available to the ELM module.

Table 7-176. Local Power Management Features

Feature	Registers	Description
Clock autogating	ELM_SYSCONFIG[0] AUTOGATING bit	This bit allows a local power optimization inside the module by gating the ELM_FCLK clock upon the interface activity.
Slave idle modes	ELM_SYSCONFIG[4:3] SIDLEMODE bit field	Force-idle, No-idle, and Smart-idle modes are available.
Clock activity	ELM_SYSCONFIG[8] CLOCKACTIVITY bit	The clock can be switched-off or maintained during the wake-up period.
Master Standby modes	N/A	
Global Wake-up Enable	N/A	
Wake-up Sources Enable	N/A	

CAUTION

The PRCM module has no hardware means of reading CLOCKACTIVITY settings. Thus, software must ensure consistent programming between the ELM CLOCKACTIVITY and ELM clock PRCM control bits.

7.4.3.3 ELM Interrupt Requests

Table 7-177 lists the event flags, and their masks, that can cause module interrupts.

Table 7-177. Events

Event Flag	Event Mask	Map to	Description
ELM_IRQSTATUS[8] PAGE_VALID	ELM_IRQENABLE[8] PAGE_MASK	ELM_IRQ	Page interrupt
ELM_IRQSTATUS[7] LOC_VALID_7	ELM_IRQENABLE[7] LOCATION_MASK_7	ELM_IRQ	Error-location interrupt for syndrome polynomial 7
ELM_IRQSTATUS[6] LOC_VALID_6	ELM_IRQENABLE[6] LOCATION_MASK_6	ELM_IRQ	Error-location interrupt for syndrome polynomial 6
ELM_IRQSTATUS[5] LOC_VALID_5	ELM_IRQENABLE[5] LOCATION_MASK_5	ELM_IRQ	Error-location interrupt for syndrome polynomial 5
ELM_IRQSTATUS[4] LOC_VALID_4	ELM_IRQENABLE[4] LOCATION_MASK_4	ELM_IRQ	Error-location interrupt for syndrome polynomial 4
ELM_IRQSTATUS[3] LOC_VALID_3	ELM_IRQENABLE[3] LOCATION_MASK_3	ELM_IRQ	Error-location interrupt for syndrome polynomial 3
ELM_IRQSTATUS[2] LOC_VALID_2	ELM_IRQENABLE[2] LOCATION_MASK_2	ELM_IRQ	Error-location interrupt for syndrome polynomial 2

Copyright © 2011, Texas Instruments Incorporated

Table 7-177. Events (continued)

Event Flag	Event Mask	Map to	Description
ELM_IRQSTATUS[1] LOC_VALID_1	ELM_IRQENABLE[1] LOCATION_MASK_1	ELM_IRQ	Error-location interrupt for syndrome polynomial 1
ELM_IRQSTATUS[0] LOC_VALID_0	ELM_IRQENABLE[0] LOCATION_MASK_0	ELM_IRQ	Error-location interrupt for syndrome polynomial 0

7.4.3.4 Processing Initialization

ELM_LOCATION_CONFIG global setting parameters must be set before using the error-location engine. The ELM_LOCATION_CONFIG[1:0] ECC_BCH_LEVEL bit defines the error-correction level used (4-,8-, or 16-bit error-correction). The ELM_LOCATION_CONFIG[26:16] ECC_SIZE bit field defines the maximum buffer length beyond which the engine processing no longer looks for errors.

The CPU can choose to use the ELM in continuous mode or page mode. If all ELM_PAGE_CTRL[i] SECTOR_i bits are reset (i is the syndrome polynomial number, i = 0 to 7), continuous mode is used. In any other case, page mode is implicitly selected.

- Continuous mode: Each syndrome polynomial is processed independently – results for a syndrome can be retrieved and acknowledged at any time, whatever the status of the other seven processing contexts.
- Page mode: Syndrome polynomials are grouped into atomic entities – only one page can be processed at any given time, even if all eight contexts are not used for this page. Unused contexts are lost and cannot be affected to any other processing. The full page must be acknowledged and cleared before moving to the next page.

For completion interrupts to be generated correctly, all ELM_IRQENABLE[i] LOCATION_MASK_i bits (i = 0 to 7) must be forced to 0 when in page mode, and set to 1 in continuous mode. Additionally, the ELM_IRQENABLE[8] PAGE_MASK bit must be set to 1 when in page mode.

The CPU initiates error-location processing by writing a syndrome polynomial into one of the eight possible register sets. Each of these register sets includes seven registers: ELM_SYNDROME_FRAGMENT_0_i to ELM_SYNDROME_FRAGMENT_6_i. The first six registers can be written in any order, but ELM_SYNDROME_FRAGMENT_6_i must be written last because it includes the validity bit, which instructs the ELM that this syndrome polynomial must be processed (the ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID bit).

As soon as one validity bit is asserted (ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID = 0x1, with i = 0 to 7), error-location processing can start for the corresponding syndrome polynomial. The associated ELM_LOCATION_STATUS_i and ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i registers are not reset (i = 0 to 7). The software must not consider them until the corresponding ELM_IRQSTATUS[i] LOC_VALID_i bit is set.

7.4.3.5 Processing Sequence

While the error-location engine is busy processing one syndrome polynomial, further syndrome polynomials can be written. They are processed when the current processing completes.

The engine completes early when:

- No error is detected; that is, when the ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE bit is set to 1 and the ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS bit field is set to 0x0.
- Too many errors are detected; that is, when the ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE bit is set to 0 while the ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS bit field is set with the value output by the error-location engine. The reported number of errors is not ensured if ECC_CORRECTABLE is 0.

If the engine completes early, the associated error-location registers ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i are not updated (i = 0 to 7).

Copyright © 2011, Texas Instruments Incorporated

In all other cases, the engine goes through the entire error-location process. Each time an error-location is found, it is logged in the associated ECC_ERROR_LOCATION bit field. The first error detected is logged in the ELM_ERROR_LOCATION_0_i[12:0] ECC_ERROR_LOCATION bit field; the second in the ELM_ERROR_LOCATION_1_i[12:0] ECC_ERROR_LOCATION bit field, and so on.

Table 7-178. ELM_LOCATION_STATUS_i Value Decoding Table

ECC_CORRECTABLE Value	ECC_NB_ERRORS Value	Status	Number of Errors Detected	Action Required
1	0	OK	0	None
1	≠ 0	OK	ECC_NB_ERRORS	Correct the data buffer read based on the ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i results.
0	Any	Failed	Unknown	Software-dependant

7.4.3.6 Processing Completion

When the processing for a given syndrome polynomial completes, its ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID bit is reset. It must not be set again until the exit status registers, ELM_LOCATION_STATUS_i (i = 0 to 7), for this processing are checked. Failure to comply with this rule leads to potential loss of the first polynomial process data output.

The error-location engine signals the process completion to the ELM. When this event is detected, the corresponding ELM_IRQSTATUS[i] LOC_VALID_i bit is set (i = 0 to 7). The processing-exit status is available from the associated ELM_LOCATION_STATUS_i register, and error locations are stored in order in the ECC_ERROR_LOCATION fields. The software must only read valid error-location registers based on the number of errors detected and located.

Immediately after the error-location engine completes, a new syndrome polynomial can be processed, if any is available, as reported by the ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID validity bit, depending on the configured error-correction level. If several syndrome polynomials are available, a round-robin arbitration is used to select one for processing.

In continuous mode (that is, all bits in ELM_PAGE_CTRL are reset), an interrupt is triggered whenever a ELM_IRQSTATUS[i] LOC_VALID_i bit is asserted. The CPU must read the ELM_IRQSTATUS register to determine which polynomial is processed and retrieve the exit status and error locations (ELM_LOCATION_STATUS_i and ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i). When done, the CPU must clear the corresponding ELM_IRQSTATUS[i] LOC_VALID_i bit by writing it to 1. Other status bits must be written to 0 so that other interrupts are not unintentionally cleared. When using this mode, the ELM_IRQSTATUS[8] PAGE_VALID interrupt is never triggered.

In page mode, the module does not trigger interrupts for the processing completion of each polynomial because the ELM_IRQENABLE[i] LOCATION_MASK_i bits are cleared. A page is defined using the ELM_PAGE_CTRL register. Each SECTOR_i bit set means the corresponding polynomial i is part of the page processing. A page is fully processed when all tagged polynomials have been processed, as logged in the ELM_IRQSTATUS[i] LOC_VALID_i bit fields. The module triggers an ELM_IRQSTATUS[8] PAGE_VALID interrupt whenever it detects that the full page has been processed. To make sure the next page can be correctly processed, all status bits in the ELM_IRQSTATUS register must be cleared by using a single atomic-write access.

NOTE: Do not modify page setting parameters in the ELM_PAGE_CTRL register unless the engine is idle, no polynomial input is valid, and all interrupts have been cleared.

Because no polynomial-level interrupt is triggered in page mode, polynomials cleared in the ELM_PAGE_CTRL[i] SECTOR_i bit fields (i = 0 to 7) are processed as usual, but are essentially ignored. The CPU must manually poll the ELM_IRQSTATUS bits to check for their status.

7.4.4 Basic Programming Model

7.4.4.1 ELM Low Level Programming Model

7.4.4.1.1 Processing Initialization

Table 7-179. ELM Processing Initialization

Step	Register/ Bit Field / Programming Model	Value
Resets the module	ELM_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset is done.	ELM_SYSSTATUS[0] RESETDONE	0x1
Configure the slave interface power management.	ELM_SYSCONFIG[4:3] SIDLEMODE	Set value
Defines the error-correction level used	ELM_LOCATION_CONFIG[1:0] ECC_BCH_LEVEL	Set value
Defines the maximum buffer length	ELM_LOCATION_CONFIG[26:16] ECC_SIZE	Set value
Sets the ELM in continuous mode or page mode	ELM_PAGE_CTRL	Set value
If continuous mode is used	All ELM_PAGE_CTRL[i] SECTOR_i (i = 0 to 7)	0x0
Enables interrupt for syndrome polynomial i	ELM_IRQENABLE[i] LOCATION_MASK_i	0x1
else (page mode is used)	One syndrome polynomial i is set ELM_PAGE_CTRL[i] SECTOR_i (i = 0 to 7)	0x1
Disable all interrupts for syndrome polynomial and enable PAGE_MASK interrupt.	All ELM_IRQENABLE[i] LOCATION_MASK_i = 0x0 and ELM_IRQENABLE[8] PAGE_MASK = 0x1	Set value
endif		Set value
Set the input syndrome polynomial i.	ELM_SYNDROME_FRAGMENT_0_i	Set value
	ELM_SYNDROME_FRAGMENT_1_i	Set value
	ELM_SYNDROME_FRAGMENT_5_i	Set value
	ELM_SYNDROME_FRAGMENT_6_i	Set value
Initiates the computation process	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID	0x1

7.4.4.1.2 Read Results

The engine goes through the entire error-location process and results can be read. Table 7-180 and Table 7-181 describe the processing completion for continuous and page modes, respectively.

Table 7-180. ELM Processing Completion for Continuous Mode

Step	Register/ Bit Field / Programming Model	Value
Wait until process is complete for syndrome polynomial i: Wait until the ELM_IRQ interrupt is generated, or poll the status register.		
Read for which i the error-location process is complete.	ELM_IRQSTATUS[i] LOC_VALID_i	0x1
if the process fails (too many errors)	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x0
It is software dependant.		
else (process successful, the engine completes)	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x1
Read the number of errors.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS	
Read the error-location bit addresses for syndrome polynomial i of the ECC_NB_ERRORS first registers. It is the software responsibility to correct errors in the data buffer.	ELM_ERROR_LOCATION_0_i[12:0] ECC_ERROR_LOCATION	
	ELM_ERROR_LOCATION_1_i[12:0] ECC_ERROR_LOCATION	
	...	
	ELM_ERROR_LOCATION_15_i[12:0] ECC_ERROR_LOCATION	

Copyright © 2011, Texas Instruments Incorporated

Table 7-180. ELM Processing Completion for Continuous Mode (continued)

Step	Register/ Bit Field / Programming Model	Value
endif		
Clear the corresponding i interrupt.	ELM_IRQSTATUS[i] LOC_VALID_i	0x1

A new syndrome polynomial can be processed after the end of processing (ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID = 0x0) and after the exit status register check (ELM_LOCATION_STATUS_i).

Table 7-181. ELM Processing Completion for Page Mode

Step	Register/ Bit Field / Programming Model	Value
Wait until process is complete for syndrome polynomial i: Wait until the ELM_IRQ interrupt is generated, or poll the status register.		
Wait for page completed interrupt: All error locations are valid.	ELM_IRQSTATUS[8] PAGE_VALID	0x1
Repeat the following actions the necessary number of times. That is, once for each valid defined block in the page.		
Read the process exit status.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	
if the process fails (too many errors)	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x0
It is software dependant.		
else (process successful, the engine completes)	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x1
Read the number of errors.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS	
Read the error-location bit addresses for syndrome polynomial i of the ECC_NB_ERRORS first registers.	ELM_ERROR_LOCATION_0_i[12:0] ECC_ERROR_LOCATION	
	ELM_ERROR_LOCATION_1_i[12:0] ECC_ERROR_LOCATION	
	...	
	ELM_ERROR_LOCATION_15_i[12:0] ECC_ERROR_LOCATION	
endif		
End Repeat		
Clear the ELM_IRQSTATUS register.	ELM_IRQSTATUS	0x1FF

Next page can be correctly processed after a page is fully processed, when all tagged polynomials have been processed (ELM_IRQSTATUS[i] LOC_VALID_i = 0x1 for all syndrome polynomials i used in the page).

7.4.4.2 Use Case: ELM Used in Continuous Mode

In this example, the ELM module is programmed for an 8-bit error-correction capability in continuous mode. After reading a 528-byte NAND flash sector (512B data plus 16B spare area) with a 16-bit interface, a non-zero polynomial syndrome is reported from the GPMC (Polynomial syndrome 0 is used in the ELM):

- P = 0x0A16ABE115E44F767BFB0D0980

Table 7-182. Use Case: Continuous Mode

Step	Register/ Bit Field / Programming Model	Value
Resets the module	ELM_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset is done.	ELM_SYSSTATUS[0] RESETDONE	0x1
Configure the slave interface power management: Smart idle is used.	ELM_SYSCONFIG[4:3] SIDLEMODE	0x2

Table 7-182. Use Case: Continuous Mode (continued)

Step	Register/ Bit Field / Programming Model	Value
Defines the error-correction level used: 8 bits	ELM_LOCATION_CONFIG[1:0] ECC_BCH_LEVEL	0x1
Defines the maximum buffer length: 528 bytes (2x528 = 1056)	ELM_LOCATION_CONFIG[26:16] ECC_SIZE	0x420
Sets the ELM in continuous mode	ELM_PAGE_CTRL	0
Enables interrupt for syndrome polynomial 0	ELM_IRQENABLE[0] LOCATION_MASK_0	0x1
Set the input syndrome polynomial 0.	ELM_SYNDROME_FRAGMENT_0_i (i=0)	0xFB0D0980
	ELM_SYNDROME_FRAGMENT_1_i (i=0)	0xE44F767B
	ELM_SYNDROME_FRAGMENT_2_i (i=0)	0x16ABE115
	ELM_SYNDROME_FRAGMENT_3_i (i=0)	0x0000000A
Initiates the computation process	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID (i=0)	0x1
Wait until process is complete for syndrome polynomial 0: IRQ_ELM is generated or poll the status register.		
Read that error-location process is complete for syndrome polynomial 0.	ELM_IRQSTATUS[0] LOC_VALID_0	0x1
Read the process exit status: All errors were successfully located.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE (i=0)	0x1
Read the number of errors: Four errors detected.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS (i=0)	0x4
Read the error-location bit addresses for syndrome polynomial 0 of the 4 first registers: Errors are located in the data buffer at decimal addresses 431, 1062, 1909, 3452.	ELM_ERROR_LOCATION_0_i (i=0)	0x1AF
	ELM_ERROR_LOCATION_1_i (i=0)	0x426
	ELM_ERROR_LOCATION_2_i (i=0)	0x775
	ELM_ERROR_LOCATION_3_i (i=0)	0xD7C
Clear the corresponding interrupt for polynomial 0.	ELM_IRQSTATUS[0] LOC_VALID_0	0x1

The NAND flash data in the sector are seen as a polynomial of degree 4223 (number of bits in a 528 byte buffer minus 1), with each data bit being a coefficient in the polynomial. When reading from a NAND flash using the GPMC module, computation of the polynomial syndrome assumes that the first NAND word read at address 0x0 contains the highest-order coefficient in the message. Furthermore, in the 16-bit NAND word, bits are ordered from bit 7 to bit 0, then from bit 15 to bit 8. Based on this convention, an address table of the data buffer can be built. NAND memory addresses in Table 7-183 are given in decimal format.

258	87	86	85	84	83	82	81	80	95	94	93	92	91	90	89	88
259	71	70	69	68	67	66	65	64	79	78	77	76	75	74	73	72
260	55	54	53	52	51	50	49	48	63	62	61	60	59	58	57	56
261	39	38	37	36	35	34	33	32	47	46	45	44	43	42	41	40
262	23	22	21	20	19	18	17	16	31	30	29	28	27	26	25	24
263	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8

The table can now be used to determine which bits in the buffer were incorrect and must be flipped. In this example, the first bit to be flipped is bit 4 from the 49th byte read from memory. It is up to the processor to correctly map this word to the copied buffer and to flip this bit. The same process must be repeated for all detected errors.

7.4.4.3 Use Case: ELM Used in Page Mode

In this example, the ELM module is programmed for an 16-bit error-correction capability in page mode. After reading a 528-byte NAND flash sector (512B data plus 16B spare area) with a 16-bit interface, four non-zero polynomial syndromes are reported from the GPMC (Polynomial syndrome 0, 1, 2, and 3 are used in the ELM):

- P0 = 0xE8B0 12ADDB5A318E05BE B0693DB28330B5CC A329AA05E0B718EF
- P1 = 0xBAD0 49A0D932C22E6669 0948DF08BE093336 79C6BA10E5F935EB
- P2 = 0x69D9 B86ABCD5EC3697FA A6498FEE54556EA0 1579EF7D60BA3189
- P3 = 0x0

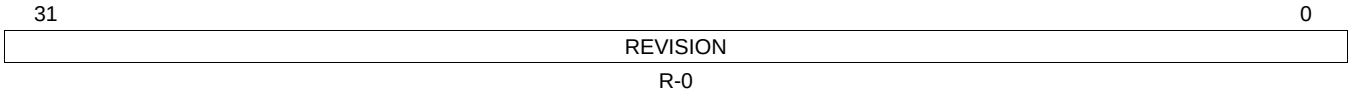
7.4.5.1 ELM Revision Register (ELM_REVISION)

This register contains the IP revision code. The ELM Revision Register (ELM_REVISION) is shown in Figure 7-152 and described in Table 7-186.

Figure 7-152. ELM Revision Register (ELM_REVISION)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

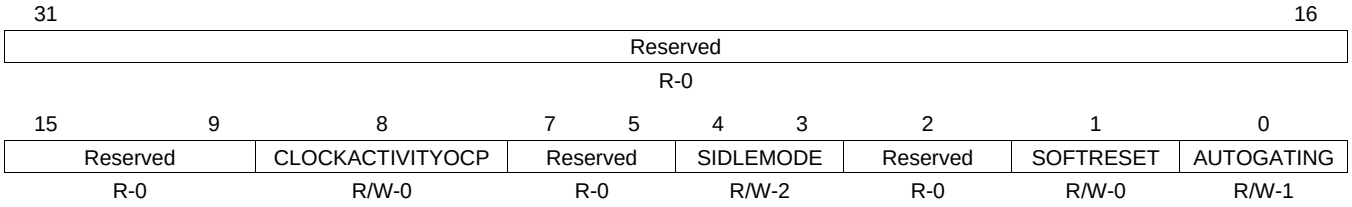
Table 7-186. ELM Revision Register (ELM_REVISION) Field Descriptions

Bit	Field	Value	Description
31-0	REVISION	0-FFFF FFFFh	IP Revision

7.4.5.2 ELM System Configuration Register (ELM_SYSCONFIG)

This register allows controlling various parameters of the OCP interface. The ELM System Configuration Register (ELM_SYSCONFIG) is shown in Figure 7-153 and described in Table 7-187.

Figure 7-153. ELM System Configuration Register (ELM_SYSCONFIG)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 7-187. ELM System Configuration Register (ELM_SYSCONFIG) Field Descriptions

Bit	Field	Value	Description
31-9	Reserved	0	Reserved
8	CLOCKACTIVITY OCP		OCP Clock activity when module is in IDLE mode (during wake up mode period).
		0	OCP Clock can be switch-off
		1	OCP Clock is maintained during wake up period
7-5	Reserved	0	Reserved
4-3	SIDLEMODE		Slave interface power management (IDLE req/ack control).
		0	FORCE Idle. IDLE request is acknowledged unconditionally and immediately. (Default *Dumb* mode for safety)
		1h	NO idle. IDLE request is never acknowledged.
		2h	SMART Idle. The acknowledgment to an IDLE request is given based on the internal activity.
		3h	Reserved - do not use
2	Reserved	0	Reserved
1	SOFTRESET		Module software reset. This bit is automatically reset by hardware (During reads, it always returns 0.). It has same effect as the OCP hardware reset.
		0	Normal mode.
		1	Start soft reset sequence.
0	AUTOGATING		Internal OCP clock gating strategy. (No module visible impact other than saving power.)
		0	OCP clock is free-running.
		1	Automatic internal OCP clock gating strategy is applied based on the OCP interface activity.

Power and Clock Management (PRCM)

This chapter describes the PRCM of the device.

Topic **Page**

8.1 Power Management and Clock Module (PRCM) 972

Copyright © 2011, Texas Instruments Incorporated

8.1 Power Management and Clock Module (PRCM)

8.1.1 Power, Reset, Clock Module

8.1.1.1 Introduction

The device power-management architecture ensures maximum performance and operation time for user satisfaction (audio/video support) while offering versatile power-management techniques for maximum design flexibility, depending on application requirements. This introduction contains the following information:

- Power-management architecture building blocks for the device
- State-of-the-art power-management techniques supported by the power-management architecture of the device

8.1.1.2 Device Power-Management Architecture Building Blocks

To provide a versatile architecture supporting multiple power-management techniques, the power-management framework is built with three levels of resource management: clock, power, and voltage management.

These management levels are enforced by defining the managed entities or building blocks of the power-management architecture, called the clock, power, and voltage domains. A domain is a group of modules or subsections of the device that share a common entity (for example, common clock source, common voltage source, or common power switch). The group forming the domain is managed by a policy manager. For example, a clock for a clock domain is managed by a dedicated clock manager within the power, reset, and clock management (PRCM) module. The clock manager considers the joint clocking constraints of all the modules belonging to that clock domain (and, hence, receiving that clock).

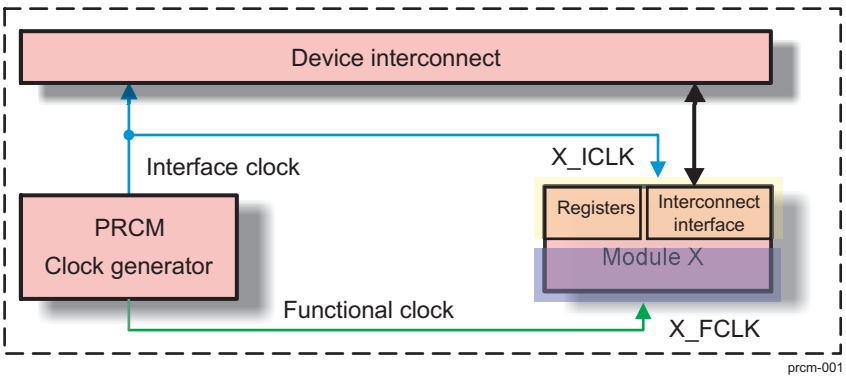
8.1.1.3 Clock Management

The PRCM module along with the control module manages the gating (that is, switching off) and enabling of the clocks to the device modules. The clocks are managed based on the requirement constraints of the associated modules. The following sections identify the module clock characteristics, management policy, clock domains, and clock domain management

8.1.1.3.1 Module Interface and Functional Clocks

Each module within the device has specific clock input characteristic requirements. Based on the characteristics of the clocks delivered to the modules, the clocks are divided into two categories: interface clocks and functional clocks

Figure 8-1. Functional and Interface Clocks



The interface clocks have the following characteristics:

- They ensure proper communication between any module/subsystem and interconnect.
- In most cases, they supply the system interconnect interface and registers of the module.

Copyright © 2011, Texas Instruments Incorporated

- A typical module has one interface clock, but modules with multiple interface clocks may also exist (that is, when connected to multiple interconnect buses).
- Interface clock management is done at the device level.
- From the standpoint of the PRCM module, an interface clock is identified by an _ICLK suffix.

Functional clocks have the following characteristics:

- They supply the functional part of a module or subsystem.
- A module can have one or more functional clocks. Some functional clocks are mandatory, while others are optional. A module needs its mandatory clock(s) to be operational. The optional clocks are used for specific features and can be shut down without stopping the module activity
- From the standpoint of the PRCM module, a functional clock is distributed directly to the related modules through a dedicated clock tree. It is identified with an _FCLK suffix

8.1.1.3.2 Module-Level Clock Management

Each module in the device may also have specific clock requirements. Certain module clocks must be active when operating in specific modes, or may be gated otherwise. Globally, the activation and gating of the module clocks are managed by the PRCM module. Hence, the PRCM module must be aware of when to activate and when to gate the module clocks. The PRCM module differentiates the clock-management behavior for device modules based on whether the module can initiate transactions on the device interconnect (called master module or initiators) or cannot initiate transactions and only responds to the transactions initiated by the master (called slave module or targets). Thus, two hardware-based power-management protocols are used:

- Master standby protocol: Clock-management protocol between the PRCM and master modules
- Slave idle protocol: Clock-management protocol between the PRCM and slave modules Master standby protocol

This protocol is used to indicate that a master module must initiate a transaction on the device interconnect and requests specific (functional and interface) clocks for the purpose. The PRCM module ensures that the required clocks are active when the master module requests the PRCM module to enable them. This is called a module wake-up transition and the module is said to be functional after this transition completes. Similarly, when the master module no longer requires the clocks, it informs the PRCM module, which can then gate the clocks to the module. The master module is then said to be in standby mode. Although the protocol is completely hardware-controlled, software must configure the clock-management behavior for the module. This is done by setting the module register bit field <Module>_SYSCONFIG. MIDLEMODE or <Module>_SYSCONFIG. STANDBYMODE. The behavior, identified by standby mode values, must be configured.

Table 8-1. Master Module Standby-Mode Settings

Standby Mode Value	Selected Mode	Description
0x0	Force-standby	The module unconditionally asserts the standby request to the PRCM module, regardless of its internal operations. The PRCM module may gate the functional and interface clocks to the module. This mode must be used carefully because it does not prevent the loss of data at the time the clocks are gated.
0x1	No-standby	The module never asserts the standby request to the PRCM module. This mode is safe from a module point of view because it ensures that the clocks remain active. However, it is not efficient from a power-saving perspective because it never allows the output clocks of the PRCM module to be gated

Copyright © 2011, Texas Instruments Incorporated

Table 8-1. Master Module Standby-Mode Settings (continued)

Standby Mode Value	Selected Mode	Description
0x2	Smart-standby	The module asserts the standby request based on its internal activity status. The standby signal is asserted only when all ongoing transactions are complete and the module is idled. The PRCM module can then gate the clocks to the module.
0x3	Smart-standbywakeup-capable mode	The module asserts the standby request based on its internal activity status. The standby signal is asserted only when all ongoing transactions are complete and the module is idle. The PRCM module can then gate the clocks to the module. The module may generate (master-related) wake-up events when in STANDBY state. The mode is relevant only if the appropriate module mwakeup output is implemented.

The standby status of a master module is indicated by the CM_<Power_domain>_<Module>_CLKCTRL[x]. STBYST bit in the PRCM module.

Table 8-2. Master Module Standby Status

STBYST Bit Value	Description
0x0	The module is functional.
0x1	The module is in standby mode

8.1.1.3.2.1 Slave Idle Protocol

This hardware protocol allows the PRCM module to control the state of a slave module. The PRCM module informs the slave module, through assertion of an idle request, when its clocks (interface and functional) can be gated. The slave can then acknowledge the request from the PRCM module and the PRCM module is then allowed to gate the clocks to the module. A slave module is said to be in IDLE state when its clocks are gated by the PRCM module. Similarly, an idled slave module may need to be wakened because of a service request from a master module or as a result of an event (called a wake-up event; for example, interrupt or DMA request) received by the slave module. In this situation the PRCM module enables the clocks to the module and then deasserts the idle request to signal the module to wake up. Although the protocol is completely hardware-controlled, software must configure the clock-management behavior for the slave module. This is done by setting the module register bit field <Module>_SYSCONFIG. SIDLEMODE or <Module>_SYSCONFIG. IDLEMODE. The behavior, listed in the Idle Mode Value column, must be configured by software.

Table 8-3. Module Idle Mode Settings

Idle Mode Value	Selected Mode	Description
0x0	Force-idle	The module unconditionally acknowledges the idle request from the PRCM module, regardless of its internal operations. This mode must be used carefully because it does not prevent the loss of data at the time the clock is switched off.
0x1	No-idle	The module never acknowledges any idle request from the PRCM module. This mode is safe from a module point of view because it ensures that the clocks remain active. However, it is not efficient from a power-saving perspective because it does not allow the PRCM module output clock to be shut off, and thus the power domain to be set to a lower power state.

Copyright © 2011, Texas Instruments Incorporated

Table 8-3. Module Idle Mode Settings (continued)

Idle Mode Value	Selected Mode	Description
0x2	Smart-idle	The module acknowledges the idle request basing its decision on its internal activity. Namely, the acknowledge signal is asserted only when all pending transactions, interrupts, or direct memory access (DMA) requests are processed. This is the best approach to efficient system power management.
0x3	Smart-idle wakeup-capable mode	The module acknowledges the idle request basing its decision on its internal wakeup-capable mode activity. Namely, the acknowledge signal is asserted only when all pending transactions, interrupts, or DMA requests are processed. This is the best approach to efficient system power management. The module may generate (IRQ- or DMA-request-related) wake-up events when in IDLE state. The mode is relevant only if the appropriate module swakeup output(s) is implemented.

The idle status of a slave module is indicated by the CM_<Powerdomain>_<Module>_CLKCTRL[x] IDLEST bit field in the PRCM module.

Table 8-4. Idle States for a Slave Module

IDLEST Bit VALUE	Idle Status	Description
0x0	Functional	The module is fully functional.The interface and functional clocks are active.
0x1	In transition	The module is performing a wake-up or a sleep transition
0x2	Interface idle	The module interface clock is idled. The module may remain functional if using a separate functional clock
0x3	Full idle	The module is fully idle. The interface and functional clocks are gated.

For the idle protocol management on the PRCM module side, the behavior of the PRCM module is configured in the CM_<Power domain>_<module>_CLKCTRL[x] MODULEMODE bit field. Based on the configured behavior, the PRCM module asserts the idle request to the module unconditionally (that is, immediately when the software requests).

Table 8-5. Slave Module Mode Settings in PRCM

MODULEMODE Bit VALUE	Selected Mode	Description
0x0	Disabled	The PRCM module unconditionally asserts the module idle request. This request applies to the gating of the functional and interface clocks to the module. If acknowledged by the module, the PRCM module can gate all clocks to the module (that is, the module is completely disabled)..
0x1	Reserved	NA

Copyright © 2011, Texas Instruments Incorporated

Table 8-5. Slave Module Mode Settings in PRCM (continued)

MODULEMODE Bit VALUE	Selected Mode	Description
0x2	Enabled	This mode applies to a module when the PRCM module manages its interface and functional clocks. The functional clock to the module remains active unconditionally, while the PRCM module automatically asserts/deasserts the module idle request based on the clock-domain transitions. If acknowledged by the module, the PRCM module can gate only the interface clock to the module.
0x3	Reserved	NA

In addition to the IDLE and STANDBY protocol, PRCM offers also the possibility to manage optional clocks, through a direct SW control: “OptFclken” bit from programming register.

Table 8-6. Module Clock Enabling Condition

Clock Enabling			
Clock associated with STANDBY protocol	AND	Clock Domain is ready	
		OR	MStandby is de-asserted
			Mwakeup is asserted
Clock associated with IDLE protocol, as interface clock	AND	Clock Domain is ready	
		OR	Idle status = FUNCT
			Idle status = TRANS
			SWakeup is asserted
Clock associated with IDLE protocol, as functional clock	AND	Clock Domain is ready	
		OR	Idle status = FUNCT
			Idle status = IDLE
			Idle status = TRANS
			SWakeup is asserted
Optional clock	AND	Clock domain is ready	
		OptFclken=Enabled ('1')	

8.1.1.3.3 Clock Domain

A clock domain is a group of modules fed by clock signals controlled by the same clock manager in the PRCM module By gating the clocks in a clock domain, the clocks to all the modules belonging to that clock domain can be cut to lower their active power consumption (that is, the device is on and the clocks to the modules are dynamically switched to ACTIVE or INACTIVE (GATED) states). Thus, a clock domain allows control of the dynamic power consumption of the device. The device is partitioned into multiple clock domains, and each clock domain is controlled by an associated clock manager within the PRCM module. This allows the PRCM module to individually activate and gate each clock domain of the device

Copyright © 2011, Texas Instruments Incorporated

Figure 8-2. Generic Clock Domain

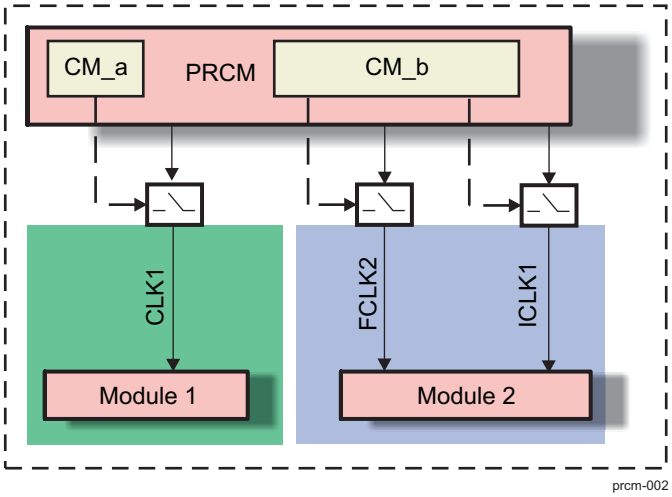


Figure above is an example of two clock managers: CM_a and CM_b. Each clock manager manages a clock domain. The clock domain of CM_b is composed of two clocks: a functional clock (FCLK2) and an interface clock (ICLK1), while the clock domain of CM_a consists of a clock (CLK1) that is used by the module as a functional and interface clock. The clocks to Module 2 can be gated independently of the clock to Module 1, thus ensuring power savings when Module 2 is not in use. The PRCM module lets software check the status of the clock domain functional clocks. The CM_<Clock domain>_CLKSTCTRL[x] CLKACTIVITY_<FCLK/Clock name_FCLK> bit in the PRCM module identifies the state of the functional clock(s) within the clock domain. Table shows the possible states of the functional clock.

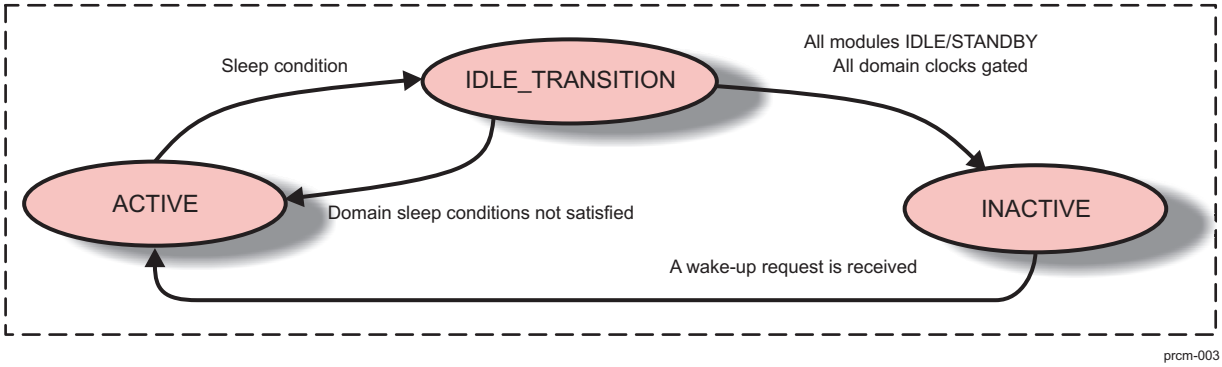
Table 8-7. Clock Domain Functional Clock States

CLKACTIVITY BIT Value	Status	Description
0x0	Gated	The functional clock of the clock domain is inactive
0x1	Active	The functional clock of the clock domain is running

8.1.1.3.3.1 Clock Domain-Level Clock Management

The domain clock manager can automatically (that is, based on hardware conditions) and jointly manage the interface clocks within the clock domain. The functional clocks within the clock domain are managed through software settings. A clock domain can switch between three possible states: ACTIVE, IDLE_TRANSITION, and INACTIVE. Figure 8-3 shows the sleep and wake-up transitions of the clock domain between ACTIVE and INACTIVE states.

Figure 8-3. Clock Domain State Transitions



Copyright © 2011, Texas Instruments Incorporated

Table 8-8. Clock Domain States

State	Description
ACTIVE	Every nondisabled slave module (that is, those whose MODULEMODE value is not set to disabled) is put out of IDLE state. All interface clocks to the nondisabled slave modules in the clock domain are provided. All functional and interface clocks to the active master modules (that is, not in STANDBY) in the clock domain are provided. All enabled optional clocks to the modules in the clock domain are provided.
IDLE_TRANSITION	This is a transitory state. Every master module in the clock domain is in STANDBY state. Every idle request to all the slave modules in the clock domain is asserted. The functional clocks to the slave module in enabled state (that is, those whose MODULEMODE values are set to enabled) remain active. All enabled optional clocks to the modules in the clock domain are provided.
INACTIVE	All clocks within the clock domain are gated. Every slave module in the clock is in IDLE state and set to disabled. Every slave module in the clock domain (that is, those whose MODULEMODE is set to disabled) is in IDLE state and set to disabled. Every optional functional clock in the clock domain is gated

Each clock domain transition behavior is managed by an associated register bit field in the CM_<Clock domain>_CLKSTCTRL[x] CLKTRCTRL PRCM module

Table 8-9. Clock Transition Mode Settings

CLKTRCTRL Bit Value	Selected Mode	Description
0x0	Reserved	NA
0x1	SW_SLEEP	A software-forced sleep transition. The transition is initiated when the associated hardware conditions are satisfied
0x2	SW_WKUP	A software-forced clock domain wake-up transition is initiated
0x3	Reserved	NA

8.1.1.4 Power Management

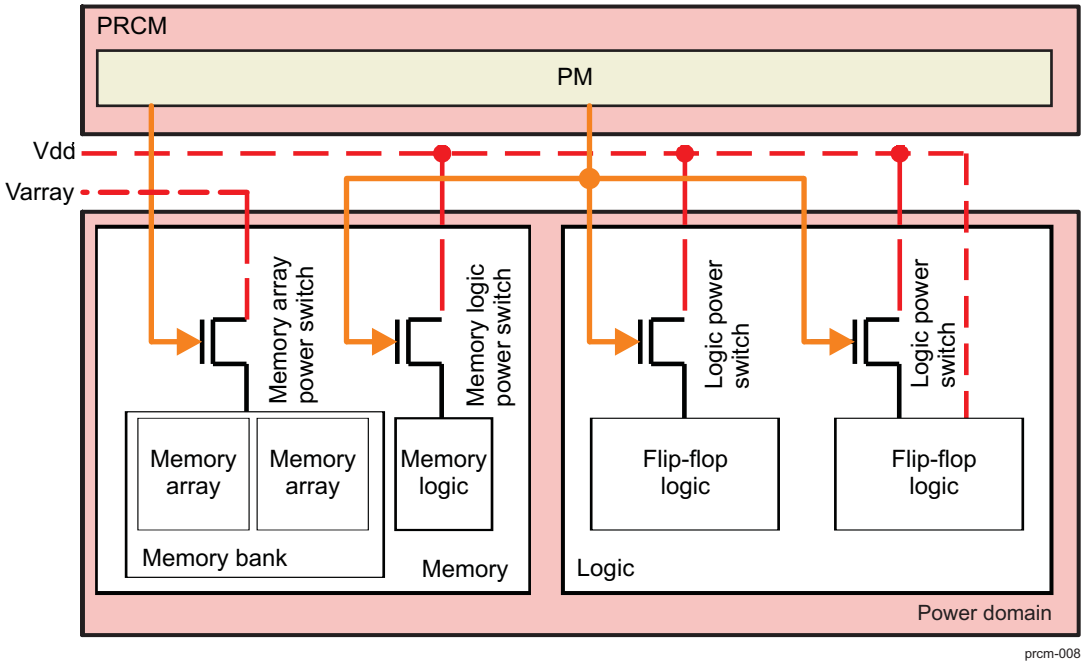
The PRCM module manages the switching on and off of the power supply to the device modules. To minimize device power consumption, the power to the modules can be switched off when they are not in use. Independent power control of sections of the device allows the PRCM module to turn on and off specific sections of the device without affecting the others.

8.1.1.4.1 Power Domain

A power domain is a section (that is, a group of modules) of the device with an independent and dedicated power manager (see Figure). A power domain can be turned on and off without affecting the other parts of the device.

Copyright © 2011, Texas Instruments Incorporated

Figure 8-4. Generic Power Domain Architecture



To minimize device power consumption, the modules are grouped into power domains. A power domain can be split into a logic area and a memory area.

Table 8-10. States of a Memory Area in a Power Domain

State	Description
ON	The memory array is powered and fully functional
OFF	The memory array is powered down

Table 8-11. States of a Logic Area in a Power Domain

State	Description
ON	Logic is fully powered
OFF	Logic power switches are off. All the logic (DFF) is lost

8.1.1.4.2 Power Domain Management

The power manager associated with each power domain is assigned the task of managing the domain power transitions. It ensures that all hardware conditions are satisfied before it can initiate a power domain transition from a source to a target power state

Table 8-12. Power Domain Control and Status Registers

Register/Bit Field	Type	Description
PM_<Power domain>_PWRSTCTRL[1:0] POWERSTATE	Control	Selects the target power state of the power domain among OFF, ON, or RETENTION.
PM_<Power domain>_PWRSTST[1:0] POWERSTATEST	Status	Identifies the current state of the power domain. It can be OFF, ON, or RETENTION.
PM_<Power domain>_PWRSTST[2] LOGICSTATEST	Status	Identifies the current state of the logic area in the power domain. It can be OFF or ON.

Copyright © 2011, Texas Instruments Incorporated

Table 8-12. Power Domain Control and Status Registers (continued)

Register/Bit Field	Type	Description
PM_<Power domain>_PWRSTST[5:4] MEMSTATEST	Status	Identifies the current state of the memory area in the power domain. It can be OFF, ON, or RETENTION

8.1.1.4.2.1 Power-Management Techniques

The following section describes the state-of-the-art power-management techniques supported by the device.

8.1.1.4.2.1.1 Adaptive Voltage Scaling

AVS is a power-management technique based in Smart Reflex that is used for automatic control of the operating voltages of the device to reduce active power consumption. With Smart Reflex, power-supply voltage is adapted to silicon performance, either statically (based on performance points predefined in the manufacturing process of a given device) or dynamically (based on the temperature-induced real-time performance of the device). A comparison of these predefined performance points to the real-time on-chip measured performance determines whether to raise or lower the power-supply voltage. AVS achieves the optimal performance/power trade-off for all devices across the technology process spectrum and across temperature variation. The device voltage is automatically adapted to maintain performance of the device

8.1.1.4.3 Power Modes

The following power modes are for easy reference applicable for typical use cases. The design does not restrict these to be the only modes. In order of the lowest power to the highest power, these modes are named RTC-Only, DeepSleep0, DeepSleep1, DeepSleep2, Standby and Active. All voltage supplies must be maintained for the each of the Deep Sleep, Standby and Active modes. In Active mode, all power domains are ON. In RTC mode, only the supplies to the RTC subsystem are supplied.

The contents of SDRAM are preserved in any of the Deep Sleep/Standby modes. This is done by placing SDRAM in self-refresh prior to entering Deep Sleep.

Table 8-13. Typical Power Modes

Use CasePower Mode	Application state	Power Domain States& Supply Voltages
RTC-Only	Only RTC voltage domain is alive. Optionally, SDRAM can be kept in self-refresh which will reduce the boot time.	VDD_MPU = 0v VDD_CORE = 0v VDDS_RTC supply is active. Optionally, IO supplies can be left ON
DeepSleep0	PD_PER peripheral & CortexA8 / MPU register information will be lost. On-chip peripheral register (context) information of PD_PER domain needs to be saved by application to SDRAM before entering this mode. SDRAM is in self-refresh. For wakeup, boot ROM executes and branches to peripheral context restore followed by system resume.	Master Oscillator = OFF VDD_MPU = 0.95v VDD_CORE = 0.95v PD_WKUP = ON PD_MPU = OFF PD_PER = OFF PD_GFX = OFF All IO supplies & RTC supplies are ON
DeepSleep1	On-chip peripheral registers are preserved. CortexA8 context/registers are lost and hence application needs to save them to MPU Subsystem or L3 OCMC RAM or SDRAM before entering DeepSleep. SDRAM is in self-refresh. For wakeup, boot ROM executes and branch to system resume.	Master Oscillator = OFF VDD_MPU = 0.95v VDD_CORE = 0.95v PD_WKUP = ON PD_MPU = OFF PD_PER = ON PD_GFX = OFF All IO supplies & RTC supplies are ON

Copyright © 2011, Texas Instruments Incorporated

Table 8-13. Typical Power Modes (continued)

Use CasePower Mode	Application state	Power Domain States& Supply Voltages
DeepSleep2	Everything is preserved including SDRAM.	Master Oscillator = OFF VDD_MPU = 0.95v VDD_CORE = 0.95v PD_WKUP = ON PD_MPU = ON PD_PER = ON PD_GFX = OFF All IO supplies & RTC supplies are ON
Standby	Everything is preserved including SDRAM. Only required module clocks are enabled, rest are clock gated.	Master Oscillator = ON One PLL is ON. VDD_MPU = 0.95v VDD_CORE = OPP50 PD_WKUP = ON PD_MPU = ON PD_PER = ON PD_GFX = OFF All IO supplies & RTC supplies are ON If more PLLs /power domains/ modules are required, the power will increase accordingly.
Active	All Features	Master Oscillator = ON One or more PLLs are ON VDD_MPU = ON VDD_CORE = ON PD_WKUP = ON PD_MPU = ON PD_PER = ON PD_GGX = ON

8.1.1.4.3.1 Active

In Active mode, the supply to all voltage rails must be maintained. All power domains come up in ON state and the device is fully functional.

8.1.1.4.3.2 Standby

In Standby mode, the supply to all voltage rails must be maintained. The power consumption can be minimized if the supply voltage placed at its minimum operating voltage. Using Software the required PLL's are made active depending upon wakeup or use case requirements and the rest are placed in low power bypass modes. All non-essential IP blocks are powered down. A peripheral interrupt to CortexM3, will cause it to un-clock gate the A8 after which A8 services the pending interrupt. SDRAM contents are preserved. This is useful for quick standby/resume kind of application.

8.1.1.4.3.3 Deepsleep0

In DeepSleep0 mode, the supply to all voltage rails are maintained, only the PD_RTC and PD_WKUP power domains are ON. The master crystal oscillator is disabled. PD_MPU is OFF. The contents of OCMC RAM are preserved. Additionally the contents of the SDRAM are preserved by placing the SDRAM in self-refresh. Activity on wake up peripherals via wake up events enables the master crystal oscillator using the oscillator control circuit. Also, the wake up events interrupt CortexM3.

8.1.1.4.3.4 Deepsleep1

In DeepSleep1 mode, the supply to all voltage rails are maintained, the PD_RTC, PD_WKUP & PD_PER

Copyright © 2011, Texas Instruments Incorporated

power domains are ON. The PD_GFX power domain is OFF (but could be optionally ON at the cost of more power). The master crystal oscillator is disabled. The contents of internal SRAM are preserved. Additionally the contents of the SDRAM are preserved by placing the SDRAM in self-refresh. Activity on wake up peripherals via wake up events enables the master crystal oscillator using the oscillator control circuit. Also, the wake up events interrupt CortexM3.

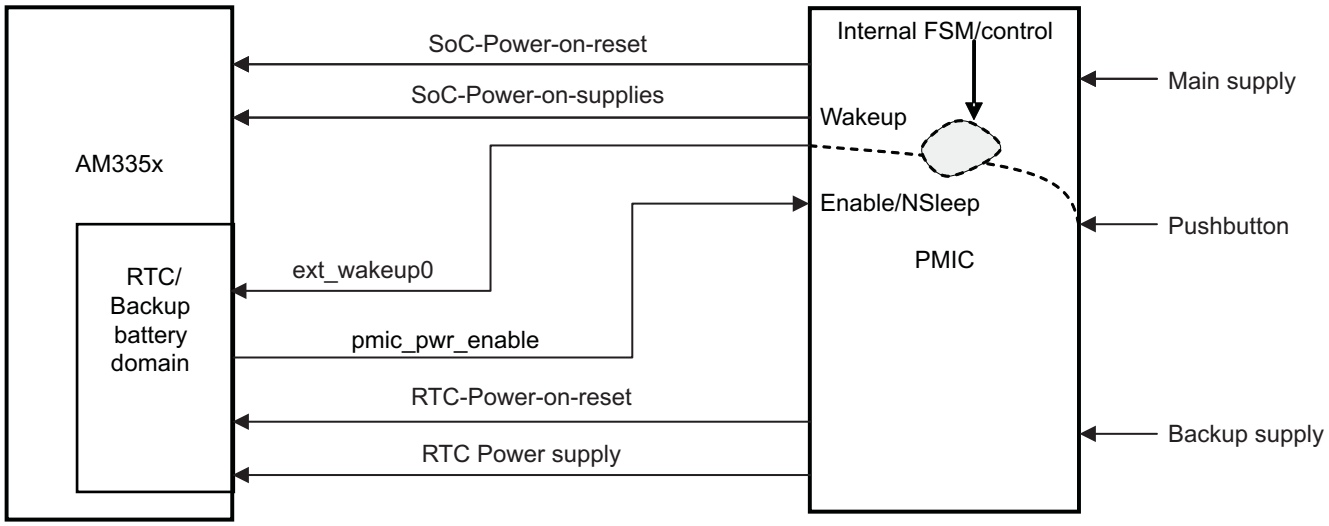
8.1.1.4.3.5 Deepsleep2

In DeepSleep2 mode, the supply to all voltage rails are maintained, all power domains are ON. The PD_GFX power domain is OFF (but could be optionally ON at the cost of more power). The master crystal oscillator is disabled. The contents of internal SRAM are preserved. Additionally the contents of the SDRAM are preserved by placing the SDRAM in self-refresh. Activity on wake up peripherals via wake events enables the master crystal oscillator using the oscillator control circuit. Also, the wake events up events interrupt CortexM3.

8.1.1.4.3.6 RTC-Only

The following diagram gives a high level view of system which implements the RTC-only mode.

Figure 8-5. High Level System View for RTC-only Mode



If RTC-only mode is not required or implemented by the end application, RTC power supply (CAP_VDD_RTC) may be connected to VDD_CORE or a separate 1.1-V power source. In addition, the RTC power-on reset (RTC_PWRONRSTn) can be connected to the SoC power-on reset (PWRONRSTn) if their power domains are at the same voltage level (i.e., VDDSHV6 is the same voltage as VDDS_RTC).

The RTC battery backup domain consists of RTCSS (subsystem), a dedicated on-chip 32.768 Hz crystal oscillator & I/Os associated with RTCSS - pmic_pwr_enable & ext_wakeup0.

In RTC-only mode, only the RTC power supply is expected to be ON. All the remaining supplies are expected to be OFF. For SDRAM to be in self-refresh during this mode, the CKE pin of the DDR interface needs to have a pull-down on the board.

8.1.1.4.4 Main Oscillator Control During Deep Sleep

The Deepsleep oscillator circuit is used to control the main oscillator by disabling it during deep sleep and enabling during active/wakeup. By default during reset, the oscillator is enabled and the oscillator control circuit comes up disabled (in-active).In order to activate the oscillator control circuit for deepsleep, DSENABLE bit of DEEPSLEEP_CTRL register must set. Once this is set and whenever wake M3 enters standby, the oscillator control will disable the oscillator causing the clock to be shut OFF. Any async event from the wakeup sources will cause the oscillator control to re-enable the oscillator after a period of DSCOUNT configured in DEEPSLEEP_CTRL register.

Copyright © 2011, Texas Instruments Incorporated

8.1.1.4.5 Wakeup Sources/Events

Following events will wake up the device from Deep sleep(low power) modes. These are part of the Wakeup Power domain and remain always ON.

- GPIO0 bank
- dmtimer1_1ms (timer based wakeup)
- USB2PHY (USB resume signaling from suspend) – Both USB ports supported.
- TSC (touch screen controller, ADC monitor functions)
- UART0 (Infra-red support)
- I2C0

These wake events apply on any of the deep sleep modes and standby mode.

8.1.1.4.6 Functional Sequencing for Power Management with Cortex M3

The AM335x device constains a dedicated Cortex M3 processor to handle the power management transitions. It is part of the Wake up Power domain (PD_WKUP). Implementing the Power modes are part of the MPU and Cortex A8 processors.

The power management sequence kicks off with Cortex A8 MPU executing a WFI instruction with the following steps:

1. During Active power mode, the Cortex A8 MPU executes a WFI instruction to enter IDLE mode.
2. Cortex M3 gets an interrupts and gets active, It powers down the MPU power domain(if required).
3. Registers interrupt for the Wake up peripheral(which is listed in Wake up sources in previous section).
4. Executes WFI and goes into idle state.
5. The wake up event triggers an interrupt to Cortex M3 system and it wakes up the Cortex A8 MPU.

Generally, A8 and CortexM3 are not expected to be active at the same time CortexM3 along with PRCM is the power manager primarily for PD_MPU and PD_PER. Other power domains (e.g., PD_GFX) may be handled directly using Cortex A8 MPU software. Figure 8-6 gives a system level view of the Power management system between Cortex A8 MPU and Cortex M3.

Copyright © 2011, Texas Instruments Incorporated

Figure 8-6. System Level View of Power Management of Cortex A8 MPU and Cortex M3

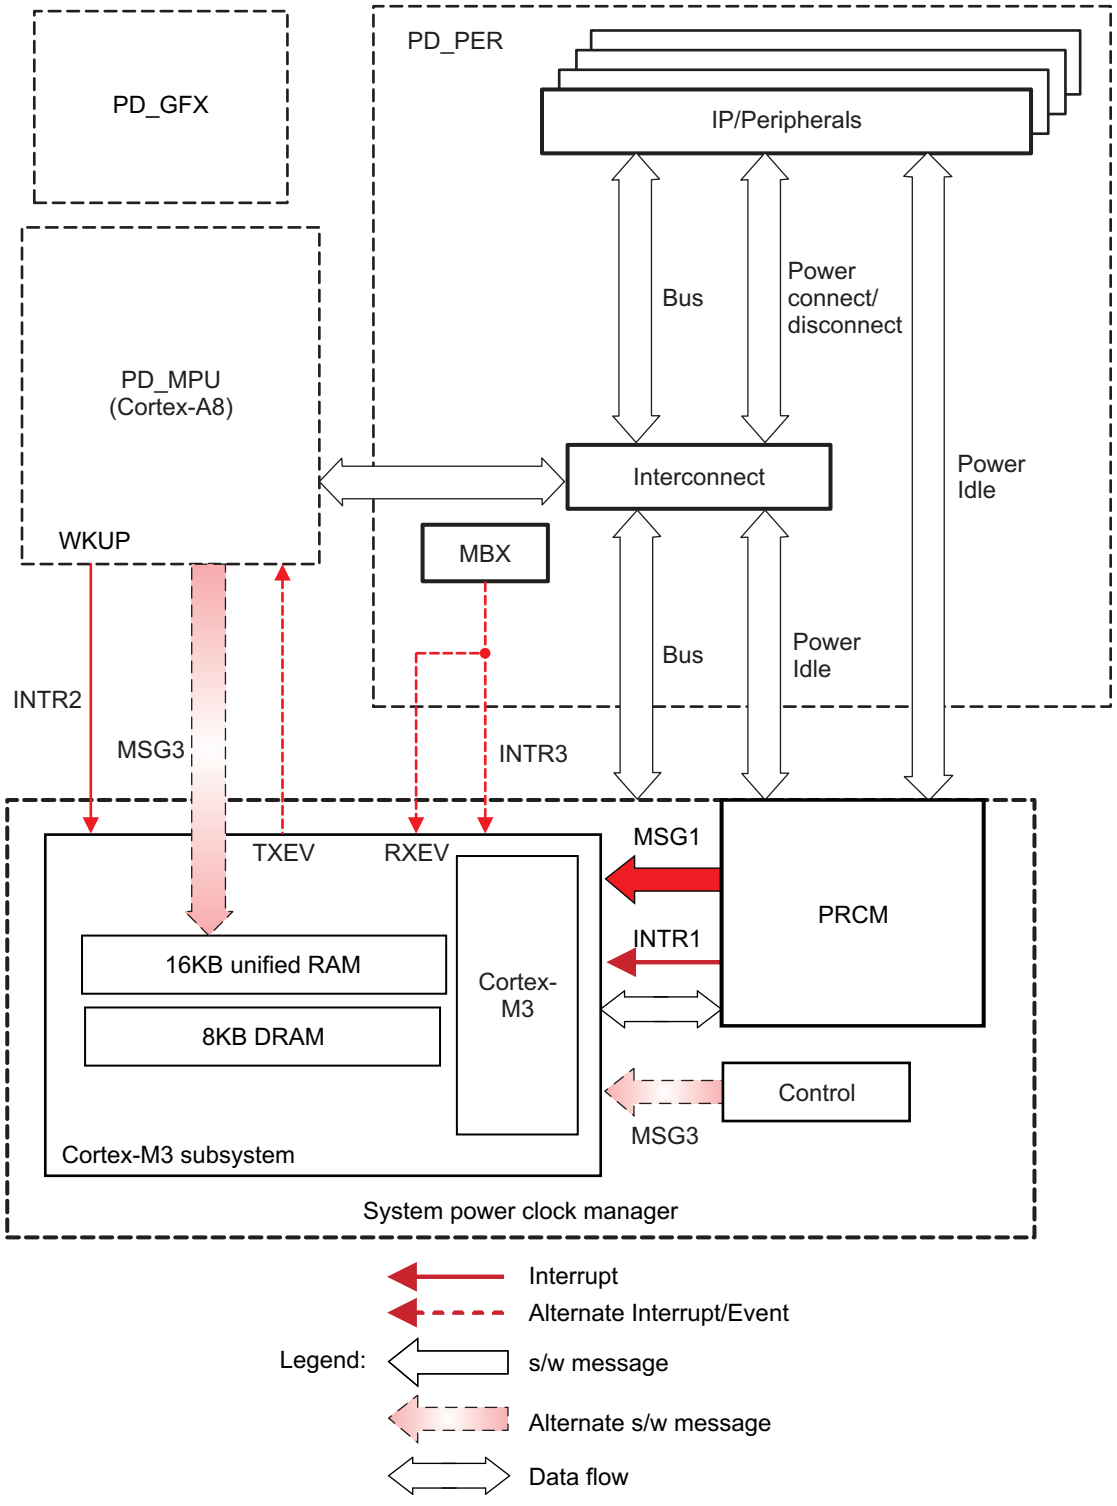


Table 8-14. M3 Interrupts 1–3

Interrupt Name	Interrupt Number in M3	Explanation
INTR1 (PRCM_M3_IRQ1)	16	Generated by PRCM when MPU power domain is clock gated.
INTR2 (PRCM_M3_IRQ2)	34	Generated by wakeup events

Copyright © 2011, Texas Instruments Incorporated

Table 8-14. M3 Interrupts 1–3 (continued)

Interrupt Name	Interrupt Number in M3	Explanation
INTR3 (MBINT0)	31	Mailbox interrupt to M3

8.1.1.4.6.1 Periodic Idling of Cortex A8 MPU

To implement Cortex A8 MPU periodic ON/OFF in the use case, the control flow could be implemented according to the following steps:

1. Cortex A8 MPU executes WFI instruction
2. Any peripheral interrupt in any of the next steps will trigger a wake interrupt to CortexM3 via MPU Subsystem's WKUP signal (INTR2 shown on the diagram). Cortex M3 powers down the MPU(PD_MPU)
3. On receiving an interrupt Cortex M3 switches ON the MPU power domain by turning on PD_MPU
4. Cortex M3 goes into idle mode using WFI instruction

8.1.1.4.6.2 Sleep Sequencing

This section gives the system level guidelines for sleep sequencing. The guidelines can serve as an example for implementing the sleep mode sequencing. The user can opt to implement a sequence with certain steps interchanged between the MPU and Cortex M3 processor.

1. Application saves context of peripherals to memories supporting retention and DDR – this step is only required for Deepsleep0.
2. MPU OCMC_RAM remains in retention
3. Unused power domains are turned OFF - program clock/power domains PWRSTCTRL, save contexts etc
4. Software populates L3_OCMC_RAM for wakeup restoration viz Save EMIF settings, public restoration pointers, etc.
5. Execute WFI from SRAM
6. Any peripheral interrupt will trigger a wake interrupt to CortexM3 via Cortex A8 MPU's WKUP signal (INTR2 shown on the diagram).
7. After MPU power domain is clock gated PRCM will provide an interrupt to CortexM3 (using INTR1 shown in the block diagram)
8. CortexM3 starts execution as follows:
   - CortexM3 configures PLL / HSDIVIDER power down States (bypass modes). During Idle bypass mode (low power mode) the PLL / HSDIVIDER goes into bypass and provides the clock outputs directly from the oscillator clock.
   - CortexM3 disables IP/Peripheral/Interconnects based on MSG1/MSG2/MSG3 sconnect/disconnect/Idle protocol kicks off and completes
   - PRCM turns OFF power domains based on MSG1/MSG2/MSG3 Only applicable for DeepSleep0 & DeepSleep1.
   - CortexM3 lowers the PMIC voltage to OPP50 voltage
   - CortexM3 configures I/O PADs for lowest power as dictated by CortexA8 using MSG2/MSG3
   - CortexM3 goes into WFI
9. Hardware oscillator control circuit disables the oscillator once CortexM3 goes into WFI

8.1.1.4.6.3 Wakeup Sequencing

This section gives the guidelines for Wakeup sequencing.

1. One of the wakeup event triggers (which was configured during the sleep sequencing) will initiate a wakeup sequence
2. The wake up event will switch on the oscillator (if it was configured to go OFF during sleep)

Copyright © 2011, Texas Instruments Incorporated

3. The wake up event will also trigger interrupt to Cortex M3
4. On the wakeup event due to interrupt Cortex M3 execute the following
   - Restore the voltages to normal Operating voltage
   - Enable PLL locking
   - Cortex M3 will switch ON the power domains and/or enable clocks for PD_PER
   - Cortex M3 will switch ON the power domains and/or enable clocks for PD_MPU
   - Executes WFI
5. Cortex A8 MPU starts executing from ROM reset vector
6. Restore the application context(only for Deep sleep 0)

8.1.1.5 PRCM Module Overview

The PRCM is structured using the architectural concepts presented in the 5000x Power Management Framework. This framework provides:

A set of modular, re-usable FSM blocks to be assembled into the full clock and power management mechanism. A register set and associated programming model. Functional sub-block definitions for clock management, power management, system clock source generation, and master clock generation.

The device supports an enhanced power management scheme based on four functional power domains:

Generic Domains

- WAKEUP
- MPU
- PER
- RTC

The PRCM provides the following functional features:

- Software configurable for direct, automatic, or a combination thereof, functional power domain state transition control
- Device power-up sequence control
- Device sleep / wake-up sequence control
- Centralized reset generation and management
- Centralized clock generation and management

The PRCM modules implement these general functional interfaces:

- OCP configuration ports
- Direct interface to device boundary
- Power switch control signals
- Device control signals
- Clocks control signals
- Resets signals
- A set of power management protocol signals for each module to control and monitor standby, idle and wake-up modes (CM and PRM)
- Emulation signals

8.1.1.5.1 Interface Descriptions

This section lists and shortly describes the different interfaces that allow PRCM to communicate with other modules or external devices.

Copyright © 2011, Texas Instruments Incorporated

8.1.1.5.1.1 OCP Interfaces

The PRCM has 1 target OCP interfaces, compliant with respect to the OCP/IP2 standard. The OCP port, for the PRCM module is used to control power, reset and wake-up Management.

8.1.1.5.1.2 OCP Slave Interfaces

PRCM implements a 32-bit OCP target interface compliant to the OCP/IP2.0 standard.

8.1.1.5.1.3 Power Control Interface

The Device does has power domain switches over the device, this interface provides PRCM control over power domain switches and receives responses from the power domains which indicate the switch status. It also controls the isolation signals. The control for power domain switches will be latched in PRCM Status Registers

8.1.1.5.1.4 Device Control Interface

This interface provides PRM management of several device-level features which are not specific to any single power domain. This PRM interface controls signals to/from the device for global control:

- Device Type coding
- IOs isolation control

8.1.1.5.1.5 Clocks Interface

This interface gathers all clock inputs and outputs managed by PRCM modules.

8.1.1.5.1.6 Resets Interface

This interface gathers all resets inputs and outputs managed by PRCM module.

8.1.1.5.1.7 Modules Power Management Control Interface

Modules or subsystems in the device are split over 2 categories:

- Initiator: an initiator is a module able to generate traffic on the device interconnects (typically: processors, MMU, EDMA).
- Target: a target is a module that cannot generate traffic on the device interconnects, but that can generate interrupts or DMA request to the system (typically: peripherals). PRCM handles a power management handshake protocol with each module or sub-system. This protocol allows performing proper clock and power transition taking into account each module activity or state.

8.1.1.5.1.8 Initiator Modules Interface

PRCM module handle all initiator modules power management interfaces: MStandby signal MWait signal

8.1.1.5.1.9 Targets Modules Interface

PRCM module handle all target modules power management interfaces: SIdleReq signal SIdleAck signal FCLKEN signal PRCM module handles all target modules wake-up: SWakeup signal

Note: USB Support for SWakeUp

8.1.1.6 Clock Generation and Management

PRCM provides a centralized control for the generation, distribution and gating of most clocks in the device. PRCM gathers external clocks and internally generated clocks for distribution to the other modules in the device. PRCM manages the system clock generation

8.1.1.6.1 Terminology

The PRCM produces 2 types of clock:

Copyright © 2011, Texas Instruments Incorporated

Interface clocks: these clocks primarily provide clocking for the system interconnect modules and the portions of device's functional modules which interface to the system interconnect modules. In most cases, the interface clock supplies the functional module's system interconnect interface and registers. For some modules, interface clock is also used as functional clock. In this specification, interface clocks are represented by blue lines.

Functional clock: this clock supplies the functional part of a module or a sub-system. In some cases, a module or a subsystem may require several functional clocks: 1 or several main functional clock(s), 1 or several optional clock(s). A module needs its main clock(s) to be operational. Optional clocks are used for specific features and can be shutdown without stopping the module

8.1.1.6.2 Clock Structure

To generate high-frequency clocks, the device supports multiple on-chip DPLLs controlled directly by the

PRCM module. They are of two types of PLLs, referred to ADPLLS and ADPLLLJ throughout this document.

The ADPLLS module is used for the Core, Display, ARM Subsystem and DDR PLLs

The ADPLLLJ module is used for the peripheral functional clocks

The device has two reference clocks which are generated by on-chip oscillators or externally. These are for the main clock tree and RTC block, respectively.

In the case of an external oscillator, a clock can directly be connected to XTALIN pin and the oscillator will be put in bypass mode. The 32-Khz crystal oscillator is controlled and configurable by RTC IP. This device also contains an on-chip RC oscillator. This oscillator is not configurable but may be enabled or disabled through the Control Module *RCOSC_CTRL* register.

The main oscillator on the device (see Chapter 26, *Initialization*, for possible frequencies) produces the master high frequency clock CLK_M_OSC.

8.1.1.6.3 ADPLLS

The ADPLLS is a high resolution frequency synthesizer PLL with built in level shifters which allows the generation of frequencies up to 1 Ghz. ADPLLS has a predivide feature which allows user to divide, for instance, a 24- or 26-MHz reference clock to 1-MHz and then multiply up to 1-GHz maximum.

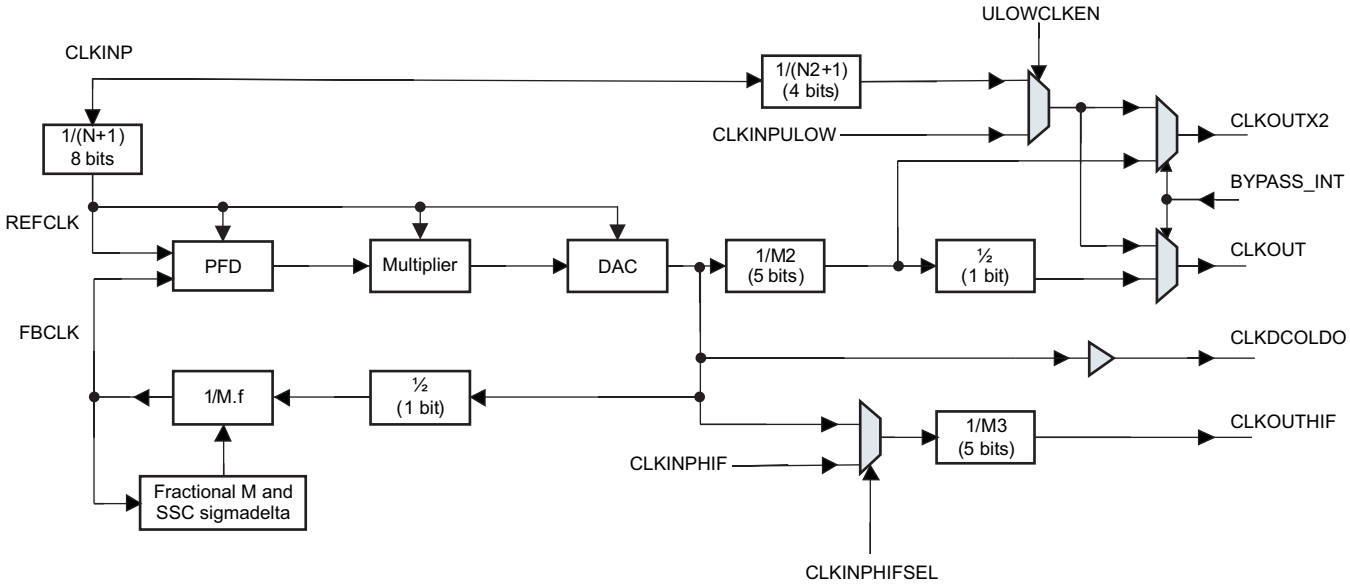
All PLLs will come-up in bypass mode at reset. SW needs to program all the pll settings appropriately and then wait for PLL to be locked. For more details, see the configuration procedure for each PLL.

The following PLLs are:

- MPU PLL
- Core PLL
- Display PLL
- DDR PLL

Copyright © 2011, Texas Instruments Incorporated

Figure 8-7. ADPLLS



The ADPLLS has three input clocks:

- CLKINP: Reference input clock
- CLKINPULOW: Low frequency input clock for bypass mode only.
- CLKINPHIF: High Frequency Input Clock for post-divider M3

The ADPLLS has four output clocks:

- CLKOUTHIF: High Frequency Output Clock from Post divider M3
- CLKOUTX2: Secondary 2x Output
- CLKOUT: Primary output clock
- CLKDCOLDO: Oscillator (DCO) output clock with no bypass

The DPLL has two internal clocks:

- REFCLK (Internal reference clock): This is generated by dividing the input clock CLKINP by the programmed value N+1. The entire loop of the PLL runs on the REFCLK.

  Here, REFCLK = CLKINP/(N+1).
- BCLK: Bus clock which is used for programming the various settings using registers

8.1.1.6.3.1 Fractional M-divider Programming

The frequency multiplication factor M can be programmed as fractional. This is achieved by having a sigma delta feedback divider (M). A fractional value (FractionalM) of 18 bits is supported enabling control to an accuracy of 1ppm. Fractional synthesis is not absolutely free in all cases, there is jitter overhead associated with it. To maintain 2.5% period jitter M should be greater than 100 for the default DPLL loop bandwidth (BW) setting. Allowing programmability of loop BW is also being evaluated to better control the jitter at lower M values.

M is the software-configured Integer Feedback Multiplier Value.

N is the software-configured Input Divider Value.

M2 is the software-configured post-divider value

N2 is the software-configured Bypass divider value.

Frac M is software-configured Fractional Feedback Multiplier.

M3 is the software-configured additional divider

8.1.1.6.3.2 Clock Functions

Table 8-15. Output Clocks in Locked Condition

Pin Name	Frequency	Comments
REGM4XEN='0'		
CLKOUT	[M / (N+1)] * CLKINP * [1/M2]	
CLKOUTX2	2 * [M / (N+1)] * CLKINP * [1/M2]	
CLKDCOLDO	2 * [M / (N+1)] * CLKINP	
CLKOUTHIF	CLKINPHIF / M3	CLKINPHIFSEL='1'
	2 * [M / (N+1)] * CLKINP * [1/M3]	CLKINPHIFSEL='0'
REGM4XEN='1'		
CLKOUT	[4M / (N+1)] * CLKINP * [1/M2]	
CLKOUTX2	2 * [4M / (N+1)] * CLKINP * [1/M2]	
CLKDCOLDO	2 * [4M / (N+1)] * CLKINP	
CLKOUTHIF	CLKINPHIF / M3	CLKINPHIFSEL='1'
	2 * [4M / (N+1)] * CLKINP * [1/M3]	CLKINPHIFSEL='0'

Table 8-16. Output Clocks Before Lock and During Relock Modes

Pin Name	Frequency	Comments
CLKOUT	CLKINP / (N2+1)	ULOWCLKEN='0'
	CLKINPULOW	ULOWCLKEN='1'
CLKOUTX2	CLKINP / (N2+1)	ULOWCLKEN='0'
	CLKINPULOW	ULOWCLKEN='1'
CLKDCOLDO	Low	
CLKOUTHIF	CLKINPHIF/M3	ULOWCLKEN='1'
	Low	ULOWCLKEN='0'

Note: Since M3 divider is running on the internal LDO domain, in the case when CLKINPHIFSEL='1', CLKOUTHIF could be active only when internal LDO is ON. Hence, whenever LDOPWDN goes low to high to powerdown LDO (happens when TINITZ activated / when entering slow relock bypass mode), output CLKOUTHIF will glitch and stop. To avoid this glitch, it is recommended to gate CLKOUTHIF using control CLKOUTHIFEN before asserting TINITZ / entering any slow relock bypass mode Frequency Range (MHz)

See the device-specific data manual for details on operating performance points (OPPs) supported by your device.

8.1.1.6.4 ADPLLLJ (Low Jitter DPLL)

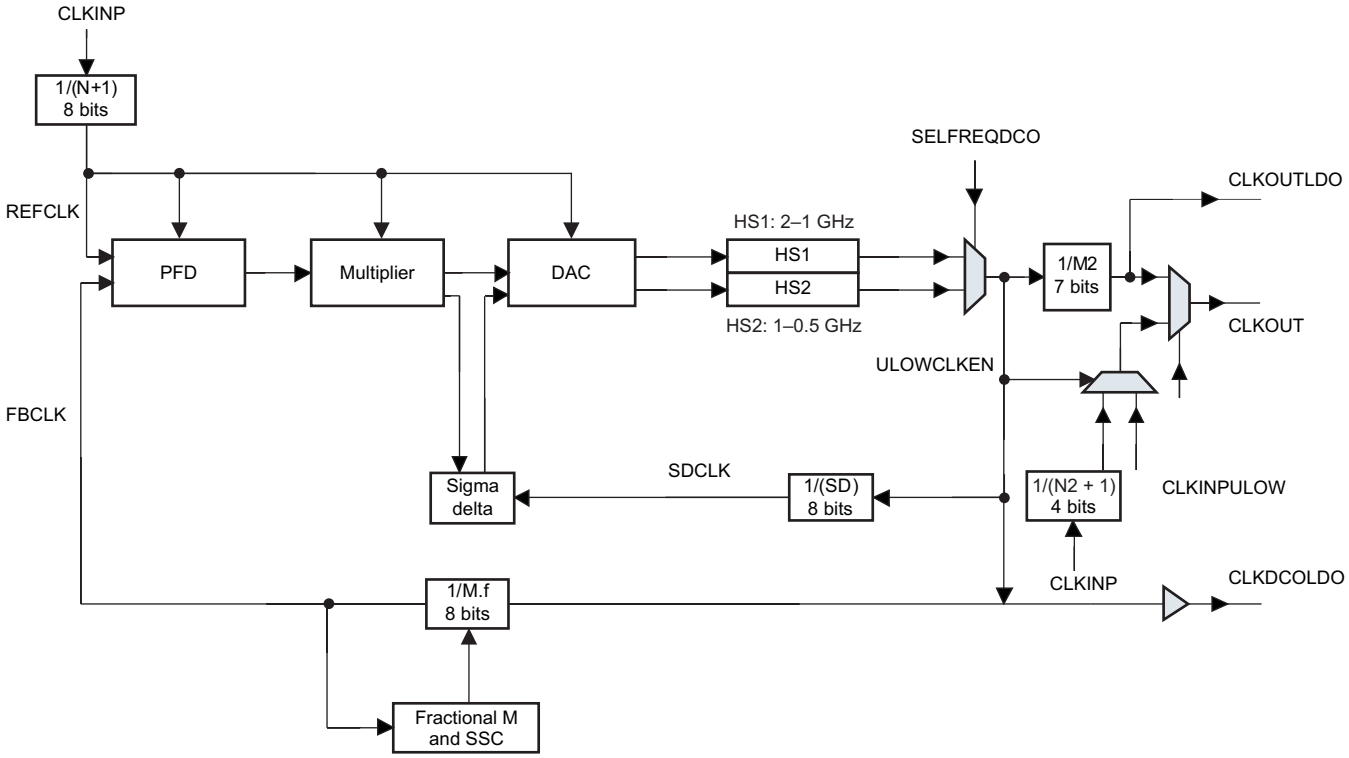
The ADPLLLJ is a low jitter PLL with a 2-GHz maximum output. ADPLLLJ has a predivide feature which allows user to divide, for instance, a 20-MHz or 27-MHz reference clock to 1MHz and then multiply up to 2-GHz maximum.

The ADPLLLJ also has a n 18b fractional multiplier which is useful for configuring very specific frequencies as desired for Audio and Video for instance.

All PLLs will come-up in bypass mode at reset. SW needs to program all the PLL settings appropriately and then wait for PLL to be locked. For more details, see the configuration procedure for each PLL.

Copyright © 2011, Texas Instruments Incorporated

Figure 8-8. Basic Structure of the ADPLLLJ



The Peripheral PLLs belong to type ADPLLLJ:

The DPLL has two input clocks:

- CLKINP: Reference input clock
- CLKINPULOW: Bypass input clock.

The DPLL has two internal clocks:

- REFCLK (Internal reference clock): This is generated by dividing the input clock CLKINP by the programmed value N+1. The entire loop of the PLL runs on the REFCLK.

  Here, REFCLK = CLKINP/(N+1).
- CLKDCO (Internal Oscillator clock.):This is the raw clock directly out of the digitally controlled oscillator (DCO) before the post-divider. The PLL output clock is synthesized by an internal oscillator which is phase locked to the refclk. There are two oscillators built within ADPLLLJ. The oscillators are user selectable based on the synthesized output clock frequency requirement. In locked condition, CLKDCO = CLKINP *[M/(N+1)].

The DPLL has three external output clocks:

- CLKOUTLDO: Primary output clock in VDDLDOOUT domain. Bypass option not available on this output.

  CLKOUTLDO = (M / (N+1))*CLKINP*(1/M2)
- CLKOUT:

  Primary output clock on digital core domain

  CLKOUT = (M / (N+1))*CLKINP*(1/M2)
- CLKDCOLDO:

  Oscillator (DCO) output clock before post-division in VDDLDOOUT domain. Bypass option is not available on this output.

  CLKDCOLDO = (M / (N+1))*CLKINP.

Copyright © 2011, Texas Instruments Incorporated

All clock outputs of the DPLL can be gated. The Control module provides the DPLL with a clock gating control signal to enable or disable the clock, and the DPLL provides the PRCM module with a clock activity status signal to let the PRCM module hardware know when the clock is effectively running or effectively gated. Output clock gating control for various clockouts: CLKOUTEN/CLKOUTLDOEN/CLKDCOLDOEN.

8.1.1.6.4.1 Fractional M-divider Programming

The frequency multiplication factor M can be programmed as fractional. This is achieved by having a sigma delta feedback divider (M). A fractional value (FractionalM) of 18 bits is supported enabling control to an accuracy of 1ppm. Fractional synthesis is not absolutely free in all cases, there is jitter overhead associated with it. To maintain 2.5% period jitter M should be greater than 100 for the default DPLL loop bandwidth (BW) setting. Allowing programmability of loop BW is also being evaluated to better control the jitter at lower M values.

M is the software-configured Integer Feedback Multiplier Value.

N is the software-configured Input Divider Value.

M2 is the software-configured post-divider value

N2 is the software-configured Bypass divider value.

SD is the software-configured Sigma2Delta Divider.

Frac M is software-configured Fractional Feedback Multiplier.

8.1.1.6.4.2 Clock Functions

Table 8-17. Output Clocks in Locked Condition

Pin Name	Frequency
CLKOUT	[M /(N+1)] * CLKINP * [1/M2]
CLKOUTLDO	[M /(N+1)] * CLKINP * [1/M2]
CLKDCOOUT	[M /(N+1)] * CLKINP

Table 8-18. Output Clocks Before Lock and During Relock Modes

Pin Name	Frequency	Comments
CLKOUT	CLKINP/(N2+1)	ULOWCLKEN='0'
	CLKINPLOW	ULOWCLKEN='1'
CLKDCOLDO	LOW	
CLKOUTLDO	LOW	

8.1.1.6.5 M2 and N2 Change On-the-Fly

The dividers M2 and N2 are designed to change on the fly and provide a glitch-free frequency switch from the old to new frequencies. In other words, they can be changed while the PLL is in a locked condition, without having to switch to bypass mode. A status toggle bit will give an indication if the new divisor was accepted. These dividers can also be changed in bypass mode, and the new divisor value will be reflected on output after the PLL relocks. For more details, see the PLL configuration procedures for each PLL.

8.1.1.6.6 Core PLL Description

The Core PLL provides the source for a majority of the device infrastructure and peripheral clocks. The Core PLL comprises an ADPLLS with HSDIVIDER and additional dividers and muxes located in the PRCM as shown in Figure 8-9.

Copyright © 2011, Texas Instruments Incorporated

CORE_CLKOUTM6	HSDIVIDER M6	-	Mstr Xtal	2	500	1	100

(1) Not all interfaces and peripheral modules are available in OPP50. For more information, see the device specific datasheet.

The ADPLLS module supports two different bypass modes via their internal MNBypass mode and their external Low Power Idle bypass mode. The PLLs are in the MNBypass mode after power-on reset and can be configured by software to enter Low Power Idle bypass mode for power-down.

When the Core PLL is configured in bypass mode, the HSDIVIDER enters bypass mode and the CLKINBYPASS input is driven on the M4, M5, and M6 outputs. CLKINBYPASS defaults to the master oscillator input (typically 24 MHz).

8.1.1.6.6.1 Core PLL Configuration

1. Switch PLL to bypass mode by setting CM_CLKMODE_DPLL_CORE.DPLL_EN to 0x4.
2. Wait for CM_IDLEST_DPLL_CORE.ST_MN_BYPASS = 1 to ensure PLL is in bypass (CM_IDLEST_DPLL_CORE.ST_DPLL_CLK should also change to 0 to denote the PLL is unlocked).
3. Configure Multiply and Divide values by setting CM_CLKSEL_DPLL_CORE.DPLL_MULT and DPLL_DIV to the desired values.
4. Configure M4, M5 and M6 dividers by setting HSDIVIDER_CLKOUT1_DIV bits in CM_DIV_M4_DPLL_CORE,CM_DIV_M5_DPLL_CORE, and CM_DIV_M6_DPLL_CORE to the desired values.
5. Switch over to lock mode by setting CM_CLKMODE_DPLL_CORE.DPLL_EN to 0x7.
6. Wait for CM_IDLEST_DPLL_CORE.ST_DPLL_CLK = 1 to ensure PLL is locked (CM_IDLEST_DPLL_CORE.ST_MN_BYPASS should also change to 0 to denote the PLL is out of bypass mode).

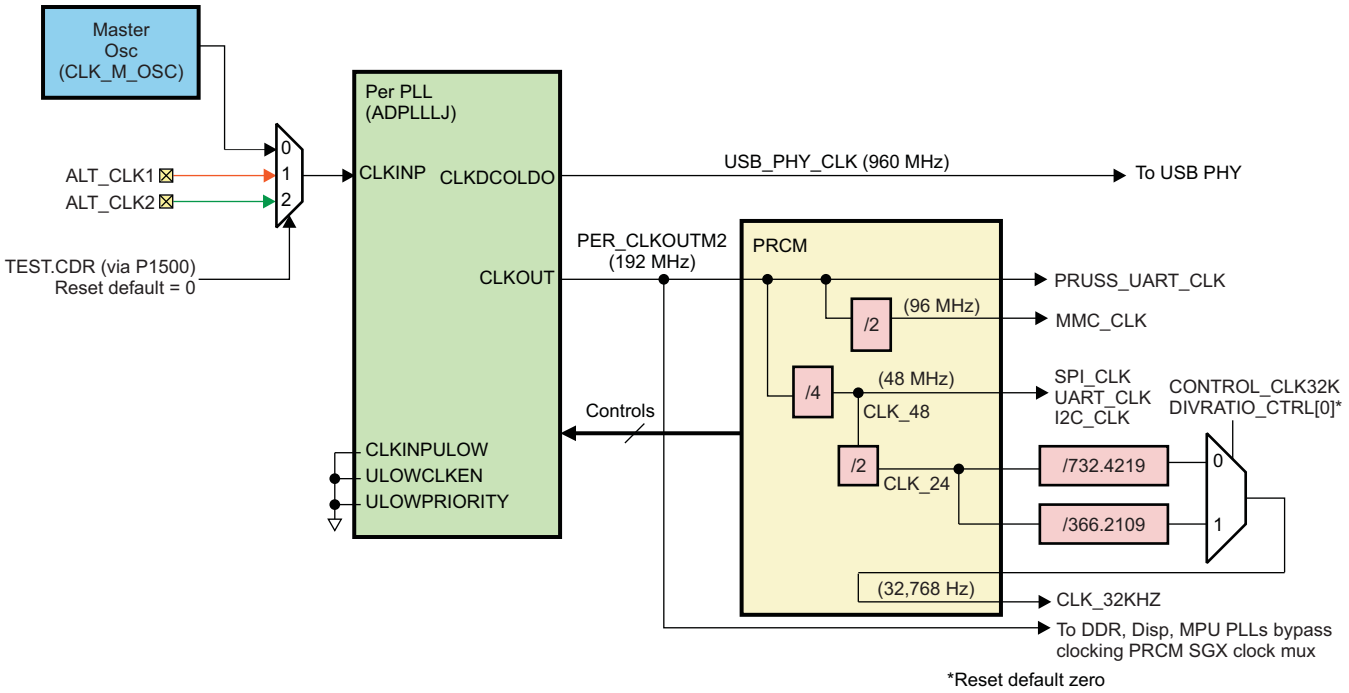
Note: M4, M5, and M6 dividers can also be changed on-the-fly so that there is no need to put the PLL in bypass and back to lock mode. After changing CM_DIV_Mx_DPLL_CORE.DPLL_CLKOUT_DIV, check CM_DIV_Mx_DPLL_CORE.DPLL_HSDIVIDER_CLKOUT1_DIVCHACK for a toggle (a change from 0 to 1 or 1 to 0) to see if the change was acknowledged by the PLL.

8.1.1.6.7 Peripheral PLL Description

The Per PLL provides the source for peripheral functional clocks. The Per PLL comprises an ADPLLLJ and additional dividers and muxes located in the PRCM as shown

Copyright © 2011, Texas Instruments Incorporated

Figure 8-10. Peripheral PLL Structure



ALT_CLKs are to be used for internal test purpose and should not be used in functional mode.

The PLL is locked at 960 MHz. The PLL output is divided by the M2 divider to generate a 192-MHz CLKOUT. This clock is gated in the PRCM to form the PRUSS UART clock. There is a /2 divider to create 96 MHz for MMC_CLK. The clock is also divided within the PRCM by a fixed /4 divider to create a 48-MHz clock for the SPI, UART and I2C modules. The 48-MHz clock is further divided by a fixed /2 divider and a fixed /732.4219 divider to create an accurate 32.768-KHz clock for Timer and debounce use.

Table 8-22. Per PLL Typical Frequencies (MHz)

Clock	Source	Power-On-Reset / PLL Bypass		Suggested Frequencies	
		DIV Value	Freq	DIV Value	Freq (MHz)
PLL Lock frequency	PLL	-	-	-	960
USB_PHY_CLK	CLKDCOLDO	-	Held Low	-	960
PER_CLKOUTM2	CLKOUT of ADPLLLJ CLKOUT uses PLL's M2 Divider when PLL is locked and PLL's N2 divider when PLL Bypass	N2 is 0 on power-on-reset	Mstr Xtal/ (N2+1)	5	192
MMC_CLK	PER_CLKOUTM2	2	Mstr Xtal/ ((N2+1)*2)	2	96
SPI_CLK, MMC_CLK, UART_CLK, I2C_CLK	PER_CLKOUTM2	4	Mstr Xtal/ ((N2+1)*4)	4	48
CLK_24	CLK_48	2	CLK_48 /2	2	24
CLK_32KHZ	CLK_24 (output of CLK_48/2)	732.4219	CLK_24 / <CLK32_DIV>	732.4219	0.032768

Copyright © 2011, Texas Instruments Incorporated

The ADPLLLJ module supports two different bypass modes via their internal MNBypass mode and their external Low Power Idle bypass mode. The PLLs are in the MNBypass mode after power-on reset and can be configured by software to enter Low Power Idle bypass mode for power-down.

The PER PLL can use the Low Power Idle bypass mode. When the internal bypass mode is selected, the CLKOUT output is driven by CLKINP/(N2+1) where N2 is driven by the PRCM. CLKINP defaults to the master oscillator input (typically 24 MHz)

8.1.1.6.7.1 Configuring the Peripheral PLL

The following steps detail how to configure the peripheral PLL.

1. Switch PLL to bypass mode by setting CM_CLKMODE_DPLL_PER.DPLL_EN to 0x4.
2. Wait for CM_IDLEST_DPLL_PER.ST_MN_BYPASS = 1 to ensure PLL is in bypass (CM_IDLEST_DPLL_PER.ST_DPLL_CLK should also change to 0 to denote the PLL is unlocked).
3. Configure Multiply and Divide values by setting CM_CLKSEL_DPLL_PER.DPLL_MULT and DPLL_DIV to the desired values.
4. Configure M2 divider by setting CM_DIV_M2_DPLL_PER.DPLL_CLKOUT_DIV to the desired value.
5. Switch over to lock mode by setting CM_CLKMODE_DPLL_PER.DPLL_EN to 0x7.
6. Wait for CM_IDLEST_DPLL_PER.ST_DPLL_CLK = 1 to ensure PLL is locked (CM_IDLEST_DPLL_PER.ST_MN_BYPASS should also change to 0 to denote the PLL is out of bypass mode).

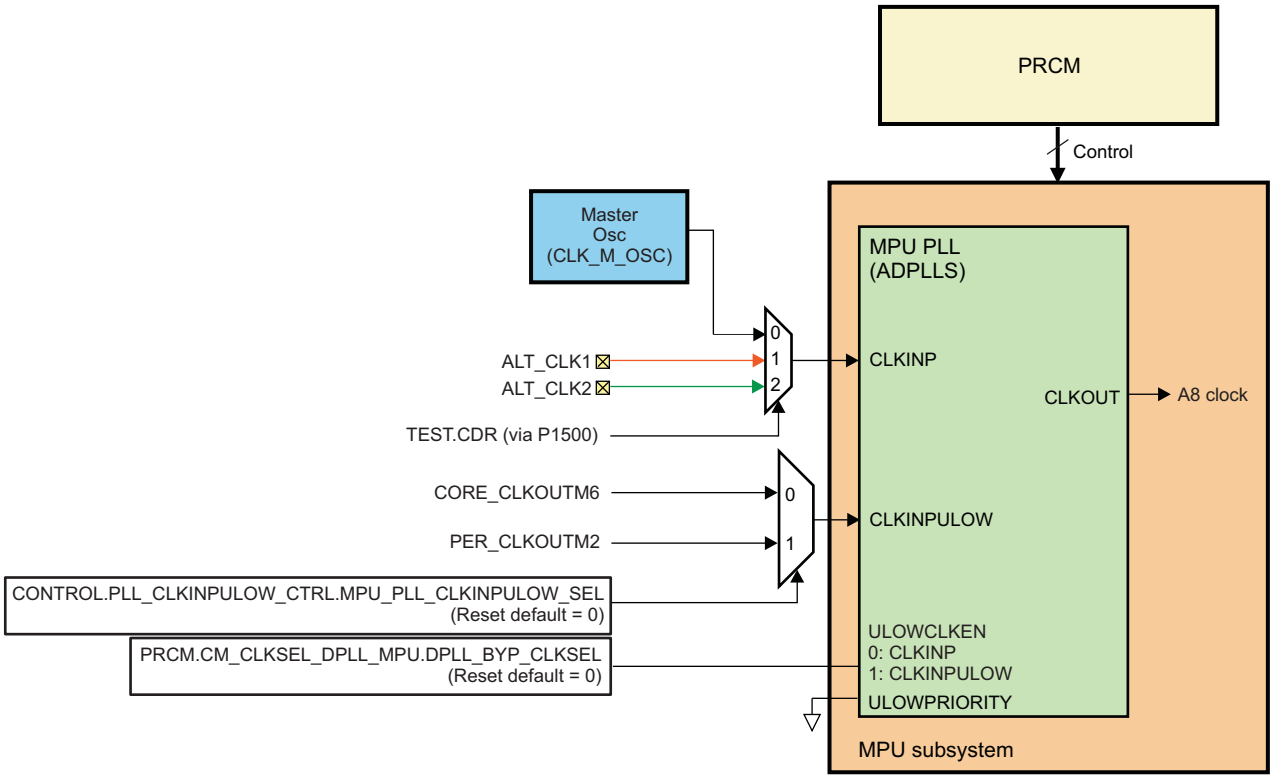
Note: M2 divider can also be changed on-the-fly (ie., there is no need to put the PLL in bypass and back to lock mode). After changing CM_DIV_M2_DPLL_PER.DPLL_CLKOUT_DIV, check CM_DIV_M2_DPLL_PER.DPLL_CLKOUT_DIVCHACK for a toggle (a change from 0 to 1 or 1 to 0) to see if the change was acknowledged by the PLL.

8.1.1.6.8 MPU PLL Description

The Cortex A8 MPU subsystem includes an internal ADPLLS for generating the required Cortex A8 MPU clocks. This PLL is driven by the master oscillator output with control provided by PRCM registers.

Copyright © 2011, Texas Instruments Incorporated

Figure 8-11. MPU Subsystem PLL Structure



For example:

For a frequency for MPU, say 600 MHz, the ADPLLS is configured (PLL locked at 1200 MHz and M2 Divider =1) so as to expect CLKOUT = 600 MHz .

The ULOWCLKEN input from a programmable PRCM register selects whether CLKINP or CLKINPULOW is the bypass clock source. This is a glitch free switch. When CLKINP is selected it is sourced through the ADPLLS 1/(N2+1) divider. The PRCM register defaults to 0 on power-up to select the CLKINP source.

The CLKINPULOW input may be sourced from the CORE_CLKOUTM6 from the Core PLL, or PER_CLKOUTM2 from the Per PLL. These PLL output clocks can be used as alternate clock sources in low power active use cases for the MPU Subsystem clock when the PLL is in bypass mode.

8.1.1.6.8.1 Configuring the MPU PLL

The following steps detail how to configure the MPU PLL.

1. Switch PLL to bypass mode by setting CM_CLKMODE_DPLL_MPU.DPLL_EN to 0x4.
2. Wait for CM_IDLEST_DPLL_MPU.ST_MN_BYPASS = 1 to ensure PLL is in bypass (CM_IDLEST_DPLL_MPU.ST_DPLL_CLK should also change to 0 to denote the PLL is unlocked).
3. Configure Multiply and Divide values by setting CM_CLKSEL_DPLL_MPU.DPLL_MULT and DPLL_DIV to the desired values.
4. Configure M2 divider by setting CM_DIV_M2_DPLL_MPU.DPLL_CLKOUT_DIV to the desired value.
5. Switch over to lock mode by setting CM_CLKMODE_DPLL_MPU.DPLL_EN to 0x7.
6. Wait for CM_IDLEST_DPLL_MPU.ST_DPLL_CLK = 1 to ensure PLL is locked (CM_IDLEST_DPLL_MPU.ST_MN_BYPASS should also change to 0 to denote the PLL is out of bypass mode).

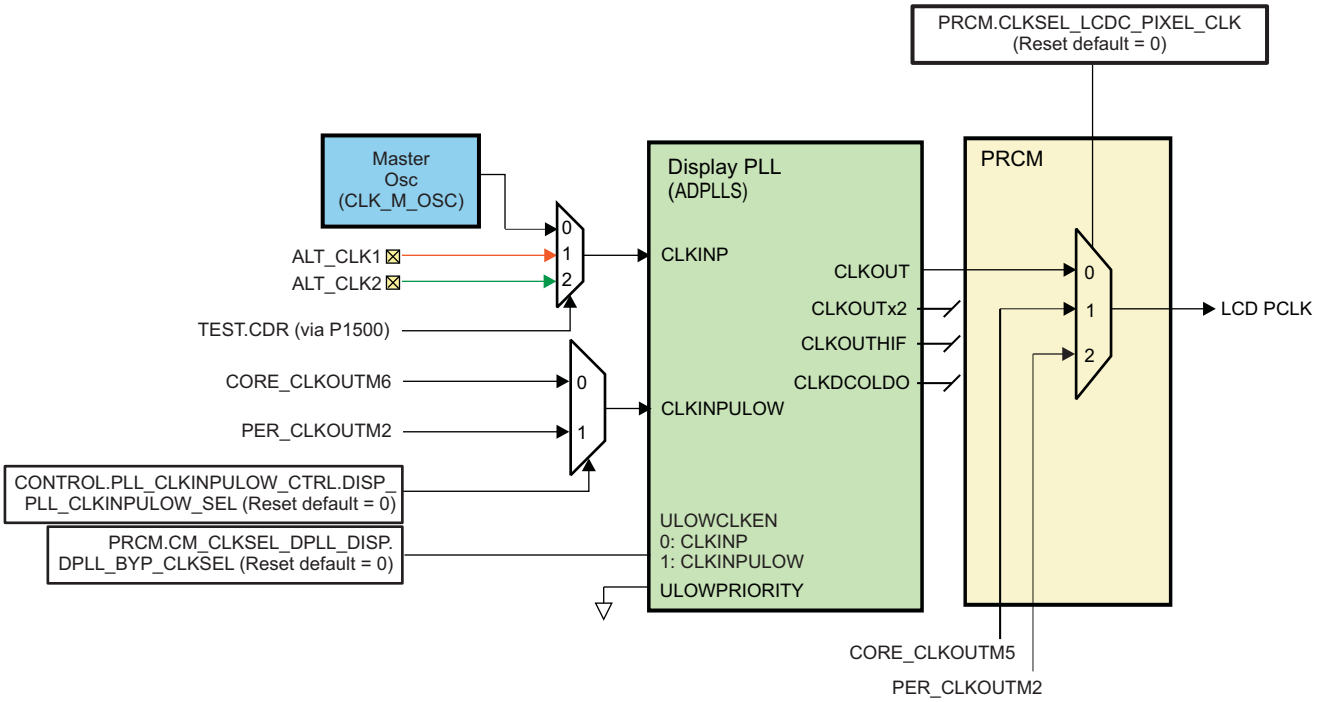
Note: M2 divider can also be changed on-the-fly (ie., there is no need to put the PLL in bypass and back to lock mode). After changing CM_DIV_M2_DPLL_MPU.DPLL_CLKOUT_DIV, check CM_DIV_M2_DPLL_MPU.DPLL_CLKOUT_DIVCHACK for a toggle (a change from 0 to 1 or 1 to 0) to see if the change was acknowledged by the PLL.

Copyright © 2011, Texas Instruments Incorporated

8.1.1.6.9 Display PLL Description

The Display PLL provides the pixel clock required for the LCD display and is independent from the other peripheral and infrastructure clocks. The PLL is clocked from the Master Oscillator. The ADPLLS M2 divider determines the output clock frequency which is clock gated by the PRCM as shown in Figure 8-12.

Figure 8-12. Display PLL Structure



For example: say frequency for pixel clock 100 MHz, the ADPLLS is configured (PLL locked at 200 MHz and M2 Divider =1) so as to expect CLKOUT = 100 MHz.

The ULOWCLKEN input from a programmable PRCM register selects whether CLKINP or CLKINPULOW is the bypass clock source. This is a glitch free switch. When CLKINP is selected it is sourced through the ADPLLS 1/(N2+1) divider. The PRCM register defaults to 0 on power-up to select the CLKINP source.

The CLKINPULOW input is sourced from the CORE_CLKOUTM6 from the Core PLL or PER_CLKOUTM2 from the Per PLL. This PLL output clock can be used as an alternate clock source in low power active use cases for the pixel clock when the Display PLL is in bypass mode.

8.1.1.6.9.1 Configuring the Display PLL

The following steps detail how to configure the display PLL.

1. Switch PLL to bypass mode by setting CM_CLKMODE_DPLL_DISP.DPLL_EN to 0x4.
2. Wait for CM_IDLEST_DPLL_DISP.ST_MN_BYPASS = 1 to ensure PLL is in bypass (CM_IDLEST_DPLL_DISP.ST_DPLL_CLK should also change to 0 to denote the PLL is unlocked).
3. Configure Multiply and Divide values by setting CM_CLKSEL_DPLL_DISP.DPLL_MULT and DPLL_DIV to the desired values.
4. Configure M2 divider by setting CM_DIV_M2_DPLL_DISP.DPLL_CLKOUT_DIV to the desired value.
5. Switch over to lock mode by setting CM_CLKMODE_DPLL_DISP.DPLL_EN to 0x7.
6. Wait for CM_IDLEST_DPLL_DISP.ST_DPLL_CLK = 1 to ensure PLL is locked (CM_IDLEST_DPLL_DISP.ST_MN_BYPASS should also change to 0 to denote the PLL is out of bypass mode).

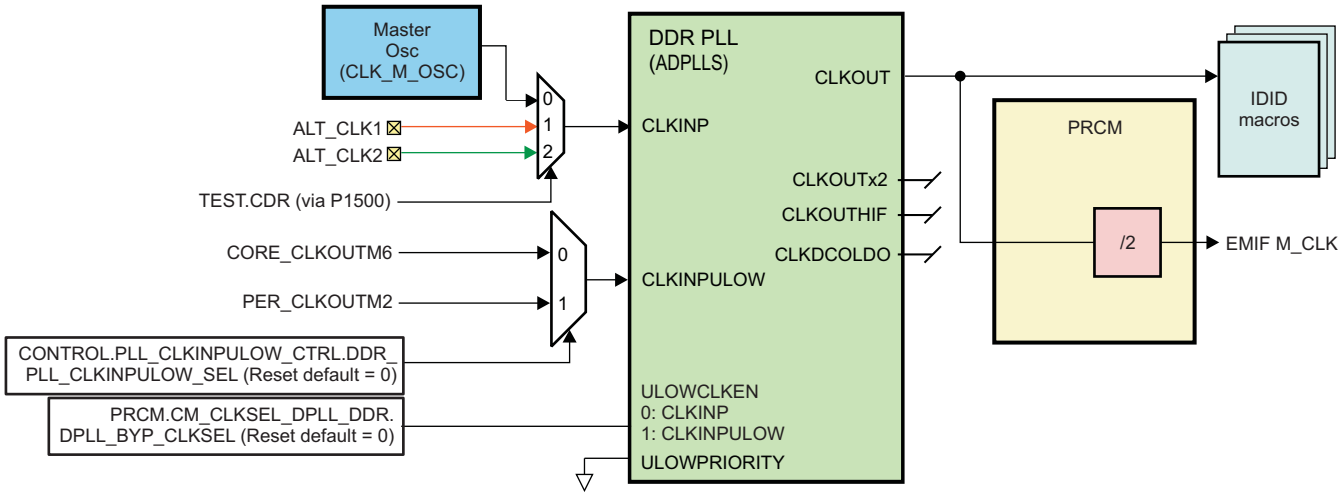
Copyright © 2011, Texas Instruments Incorporated

Note: M2 divider can also be changed on-the-fly (ie., there is no need to put the PLL in bypass and back to lock mode). After changing CM_DIV_M2_DPLL_DISP.DPLL_CLKOUT_DIV, check CM_DIV_M2_DPLL_DISP.DPLL_CLKOUT_DIVCHACK for a toggle (a change from 0 to 1 or 1 to 0) to see if the change was acknowledged by the PLL.

8.1.1.6.10 DDR PLL Description

The DDR PLL provides the clocks required by the DDR macros and the EMIF and is independent from the other peripheral and infrastructure clocks. The PLL is clocked from the Master Oscillator. The ADPLLS M2 divider determines the output clock frequency which is connected directly to the DDR Macros. The clock is also routed through the PRCM where a fixed /2 divider is used to create the M_CLK used by the EMIF as shown in Figure 8-13.

Figure 8-13. DDR PLL Structure



For OPP information, see the device-specific data manual.

Example frequency for DDR clock, say 266 MHz, the ADPLLS is configured (PLL locked at 532 MHz and M2 Divider =1) so as to expect CLKOUT = 266 MHz.

The ULOWCLKEN input from a programmable PRCM register selects whether CLKINP or CLKINPULOW is the bypass clock source. This is a glitch free switch. When CLKINP is selected it is sourced through the ADPLLS 1/(N2+1) divider. The PRCM register defaults to 0 on power-up to select the CLKINP source.

The CLKINPULOW input may be sourced from the CORE_CLKOUTM6 from the Core PLL, or PER_CLKOUTM2 from the Per PLL. These PLL output clocks can be used as alternate clock sources in low power active use cases for the DDR clocks when PLL is in bypass mode

8.1.1.6.10.1 Configuring the DDR PLL

The following steps detail how to configure the DDR PLL.

1. Switch PLL to bypass mode by setting CM_CLKMODE_DPLL_DDR.DPLL_EN to 0x4.
2. Wait for CM_IDLEST_DPLL_DDR.ST_MN_BYPASS = 1 to ensure PLL is in bypass (CM_IDLEST_DPLL_DDR.ST_DPLL_CLK should also change to 0 to denote the PLL is unlocked).
3. Configure Multiply and Divide values by setting CM_CLKSEL_DPLL_DDR.DPLL_MULT and DPLL_DIV to the desired values.
4. Configure M2 divider by setting CM_DIV_M2_DPLL_DDR.DPLL_CLKOUT_DIV to the desired value.
5. Switch over to lock mode by setting CM_CLKMODE_DPLL_DDR.DPLL_EN to 0x7.
6. Wait for CM_IDLEST_DPLL_DDR.ST_DPLL_CLK = 1 to ensure PLL is locked (CM_IDLEST_DPLL_DDR.ST_MN_BYPASS should also change to 0 to denote the PLL is out of bypass mode).

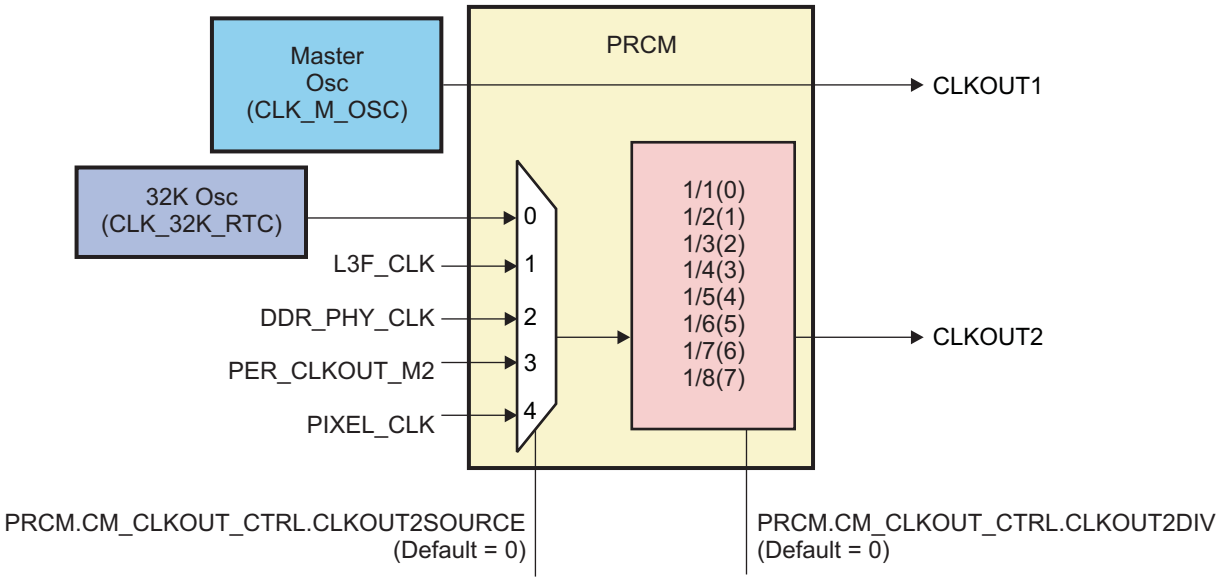
Copyright © 2011, Texas Instruments Incorporated

Note: M2 divider can also be changed on-the-fly (ie., there is no need to put the PLL in bypass and back to lock mode). After changing CM_DIV_M2_DPLL_DDR.DPLL_CLKOUT_DIV, check CM_DIV_M2_DPLL_DDR.DPLL_CLKOUT_DIVCHACK for a toggle (a change from 0 to 1 or 1 to 0) to see if the change was acknowledged by the PLL.

8.1.1.6.11 CLKOUT Signals

The CLKOUT1 and CLKOUT2 signals go device pads and can be used as source clocks for FPGAs or other system devices. CLKOUT1 created from the master oscillator. CLKOUT2 can be sourced from the 32-KHz crystal oscillator or any of the PLL (except MPU PLL) outputs. The selected output can be further modified by a programmable divider to create the desired output frequency.

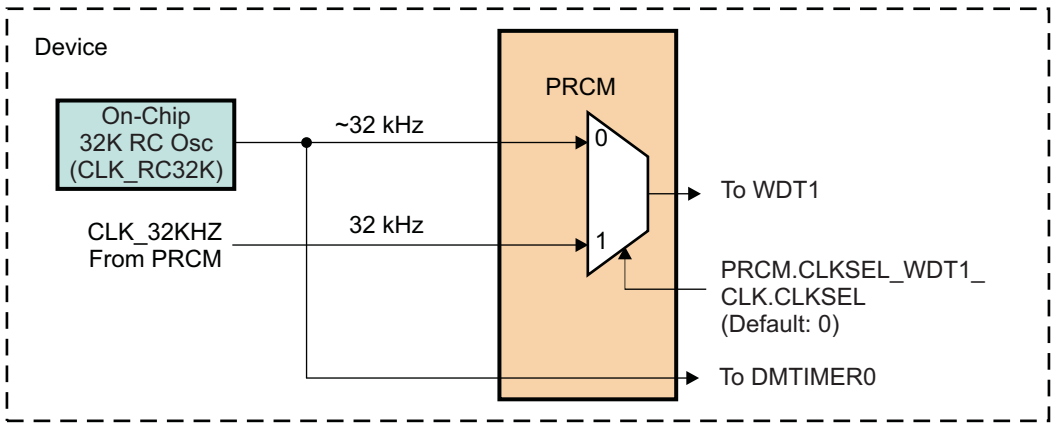
Figure 8-14. CLKOUT Signals



8.1.1.6.12 Timer Clock Structure

The CLK_32KHZ clock is an accurate 32.768-MHz clock derived from the PER PLL and can also be selected for the WDT1. The DMTIMER0 can only be clocked from the internal RC oscillator (CLK_RC32K). The clock options are shown in Figure 8-15.

Figure 8-15. Watchdog Timer Clock Selection



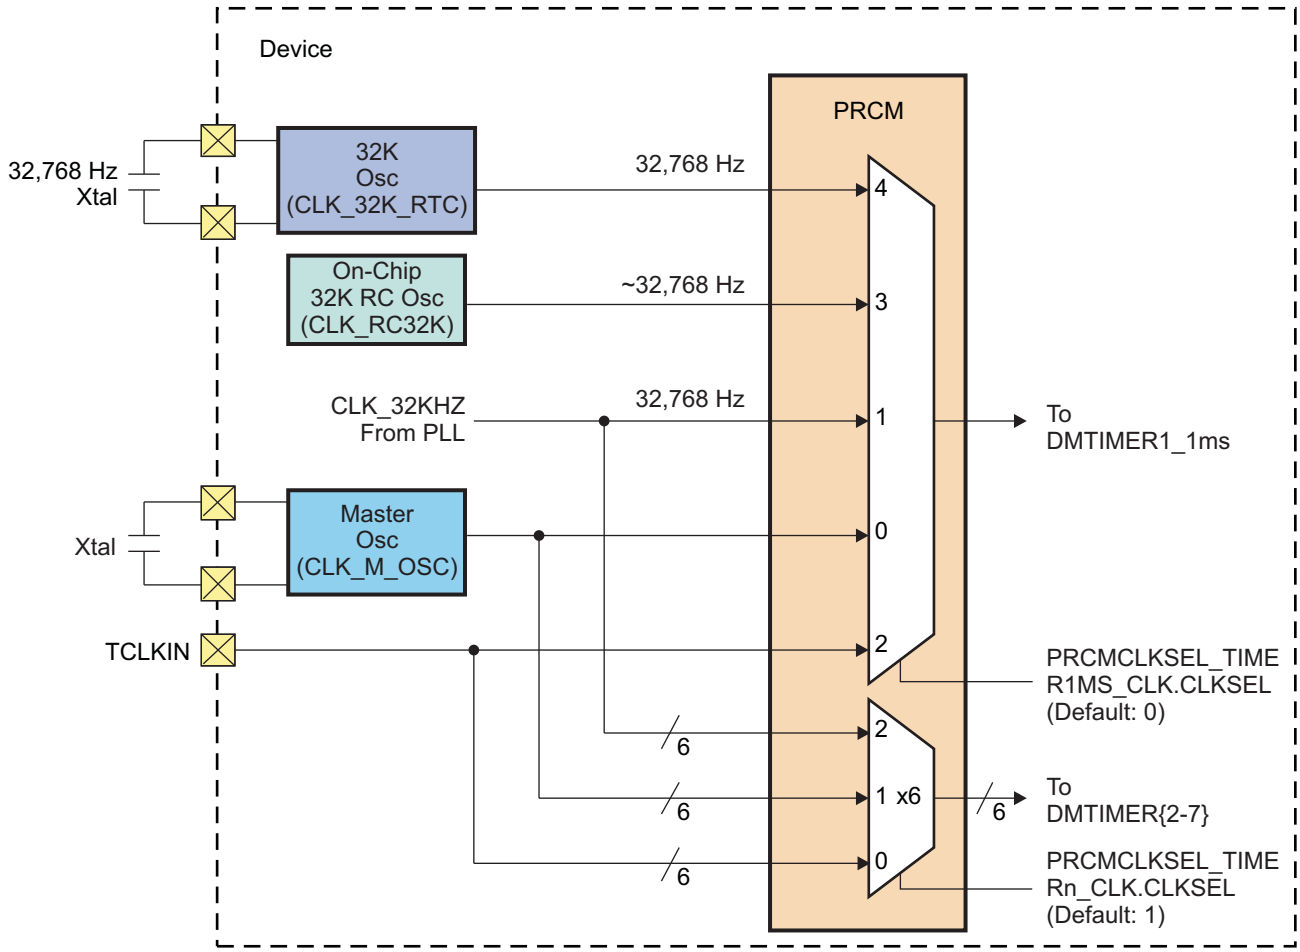
All mux selections are in PRCM unless explicitly shown otherwise in the diagrams.

Copyright © 2011, Texas Instruments Incorporated

The clock selections for the other device Timer modules are shown in Figure 8-16. CLK_32KHZ, the master oscillator, and the external pin (TCLKIN) are optional clocks available for timers which may be selected based on end use application.

DMTIMER1 is implemented using the DMTimer_1ms module which is capable of generating an accurate 1ms tick using a 32.768 KHz clock. During low power modes, the Master Oscillator is disabled. CLK_32KHZ also would not be available in this scenario since it is sourced from the Master Osc based PER PLL. Hence, in low power modes DMTIMER1 in the WKUP domain can use the 32K RC oscillator for generating the OS (operating system) 1ms tick generation and timer based wakeup. Since most applications expect an accurate 1ms OS tick which the inaccurate 32K RC (16-60 KHz) oscillator cannot provide, a separate 32768 Hz oscillator (32K Osc) is provided as another option.

Figure 8-16. Timer Clock Selection



All mux selections are in PRCM unless explicitly shown otherwise in the diagrams.

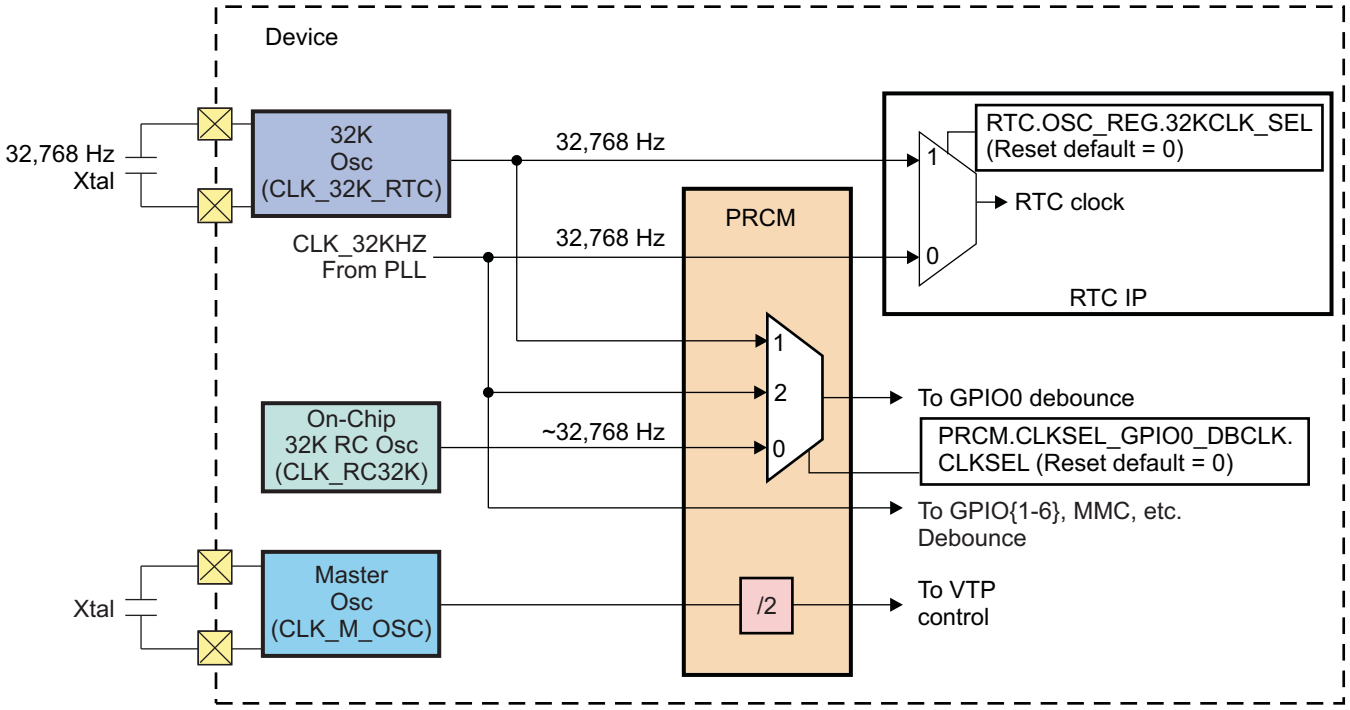
The RTC, Debounce and VTP clock options are shown in Figure 8-17. In low power modes, the debounce for GPIO0 in WKUP domain can use the accurate 32768 Hz crystal oscillator or the inaccurate (16 KHz to 60 KHz) 32K RC oscillator when the Master Osc is powered down.

The 32K Osc requires an external 32768-Hz crystal.

All mux selections are in PRCM unless explicitly shown otherwise in the diagrams.

Copyright © 2011, Texas Instruments Incorporated

Figure 8-17. RTC, VTP, and Debounce Clock Selection



All mux selections are in PRCM unless explicitly shown otherwise in the diagrams.

8.1.1.6.13 Device Clocking from External Sources

Table 8-23. Clock Names from External Sources

Clock Name	Description
SYS_CLKIN	19.2, 24, 25, or 26-MHz clock
clk_32768	32-kHz clock from RTC crystal oscillator
clk_rc32k	32-kHz clock from RC oscillator
clk_32khz	32-kHz clock from fractional divider
TCLKIN	Timer clock

8.1.1.7 Reset Management

8.1.1.7.1 Overview

The PRCM manages the resets to all power domains inside device and generation of a single reset output signal through device pin, PWRONRSTn, for external use. The PRCM has no knowledge of or control over resets generated locally within a module, e.g., via the OCP configuration register bit IPName_SYSCONFIG.SoftReset.

All PRM reset outputs are asynchronously asserted. These outputs are active-low except for the PLL resets. Deassertion is synchronous to the clock which runs a counter used to stall, or delay, reset de-assertion upon source deactivation. This clock will be SYS_CLK used by all the reset managers. All modules receiving a PRCM generated reset are expected to treat the reset as asynchronous and implement local re-synchronization upon de-activation as needed.

One or more Reset Managers are required per power domain. Independent management of multiple reset domains is required to meet the reset sequencing requirements of all modules in the power domain

Copyright © 2011, Texas Instruments Incorporated

8.1.1.7.2 Reset Concepts and Definitions

The PRCM collects many sources of reset. Here below is a list of qualifiers of the source of reset:

- Cold reset: it affects all the logic in a given entity
- Warm reset: it is a partial reset which doesn't affect all the logic in a given entity
- Global reset: it affects the entire device
- Local reset: it affects part of the device (1 power domain for example)
- S/W reset: it is initiated by software
- H/W reset: it is hardware driven

Each reset source is specified as being a cold or warm type. Cold types are synonymous with power-on-reset (POR) types. Such sources are applied globally within each receiving entity (i.e., sub-system, module, macro-cell) upon assertion. Cold reset events include: device power-up, power-domain power-up, and eFuse programming failures.

Warm reset types are not necessarily applied globally within each receiving entity. A module may use a warm reset to reset a subset of its logic. This is often done to speed-up reset recovery time, i.e., the time to transition to a safe operating state, compared to the time required upon receipt of a cold reset. Warm reset events include: software initiated per power-domain, watch-dog time-out, externally triggered, and emulation initiated.

Reset sources, warm or cold types, intended for device-wide effect are classified as global sources. Reset sources intended for regional effect are classified as local sources.

Each Reset Manager provides two reset outputs. One is a cold reset generated from the group of global and local cold reset sources it receives. The other is a warm+cold reset generated from the combined groups of, global and local, cold and warm reset sources it receives.

The Reset Manager asserts one, or both, of its reset outputs asynchronously upon reset source assertion. Reset deassertion is extended beyond the time the source gets de-asserted. The reset manager will then extend the active period of the reset outputs beyond the release of the reset source, according to the PRCM's internal constraints and device's constraints. Some reset durations can be software-configured. Most (but not all) reset sources are logged by PRCM's reset status registers. The same reset output can generally be activated by several reset sources and the same reset source can generally activate several reset outputs. All the reset signals output of the PRCM are active low. Several conventions are used in this document for signal and port names. They include:

- "_RST" in a signal or port name is used to denote reset signal.
- "_PWRON_RST" in a signal or port name is used to denote a cold reset source

8.1.1.7.3 Global Power On Reset (Cold Reset)

There are several cold reset sources. See Table 8-24 for a summary of the different reset sources.

8.1.1.7.3.1 Power On Reset (PORz)

The source of power on reset is PORz signal on the device. Everything on device is reset with assertion of power on reset. This reset is non-blockable. PORz can be driven by external power management devices or power supervisor circuitry. During power-up, when power supplies to the device are ramping up, PORz needs to be driven Low. When the ramp-up is complete and supplies reach their steady-state values, PORz need to be driven High. During normal operation when any of the device power supplies are turned OFF, PORz must be driven Low.

8.1.1.7.3.2 PORz Sequence

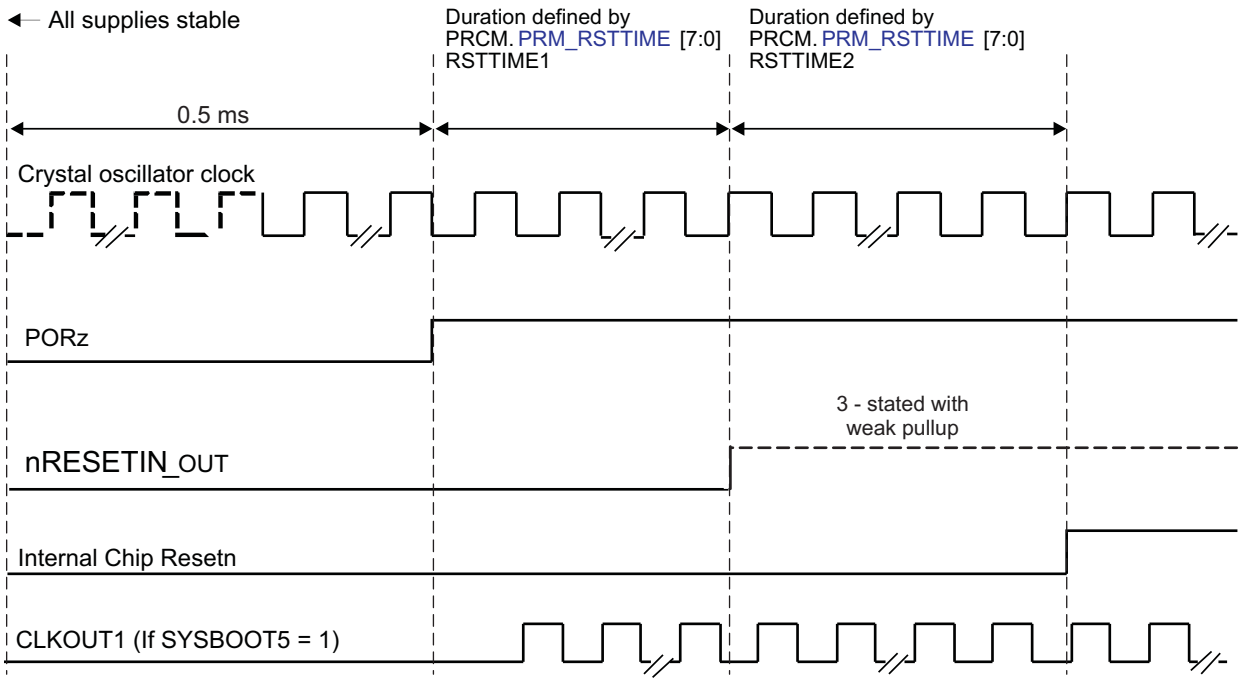
- PORz pin at chip boundary gets asserted (goes low). **Note**: state of nRESETIN_OUT during PORz assertion should be a don't care, it should not affect PORz (only implication is if they are both asserted and nRESETIN_OUT is deasserted after PORz you will get re-latching of boot config pins and may see warm nRESETIN_OUT flag set in PRCM versus POR).
- All IOs will go to tri-state immediately.
- When power comes-up, PORz value will propagate to the PRCM.

Copyright © 2011, Texas Instruments Incorporated

- PRCM will fan out reset to the complete chip and all logic which uses async reset will get reset. nRESETIN_OUT will go low to indicate reset-in-progress.
- External clocks will start toggling and PRCM will propagate these clocks to the chip keeping PLLs in bypass mode.
- All logic using sync reset will get reset.
- When power and clocks to the chip are stable, PORz must be de-asserted.
- Boot configuration pins are latched upon de-assertion of PORz pin
- IO cell controls from IPs for all the IOs with a few exceptions (see datasheet for details) are driven by GPIO module. GPIO puts all IOs in input mode.
- FuseFarm reset will be de-asserted to start eFuse scanning.
- Once eFuse scanning is complete, reset to the host processor and to all other peripherals (peripherals without local processor) will be de-asserted.
- nRESETIN_OUT will be de-asserted after time defined by PRM_DEVICE_RSTTIME1.
- Once host processors finish booting then all remaining peripherals will see reset de-assertion.

Note that all modules with local CPUs will have local reset asserted by default at PORz and reset de-assertion would require host processor to write to respective registers in PRCM.

Figure 8-18. PORz



8.1.1.7.3.3 Bad Device Reset

This reset is asserted whenever the DEVICE_TYPE encodes an unsupported device type, such as the code for a "bad" device.

8.1.1.7.3.4 Global Cold Software Reset (GLOBAL_COLD_SW_RST)

The source for GLOBAL_COLD_SW_RST is generated internally by the PRM. It is activated upon setting the PRM_RSTCTRL.RST_GLOBAL_COLD_SW bit in the PRM memory map. This bit is self-clearing, i.e., it is automatically cleared by the hardware.

Copyright © 2011, Texas Instruments Incorporated

8.1.1.7.4 Global Warm Reset

8.1.1.7.4.1 External Warm Reset

nRESETIN_OUT is a bidirectional warm reset signal. As an input, it is typically used by an external source as a device reset. Refer to Table 8-24 for a summary of the differences between a warm reset and cold reset. Some of these differences are:

- The warm reset can be blocked to the EMAC switch and its reference clock source PLL using the RESET_ISO register in the Control Module.
- The warm reset assumes that clocks and power to the chip are stable from assertion through deassertion, whereas during the cold reset, the power supplies can become stable during assertion
- Some PRCM and Control module registers are warm reset insensitive and maintain their value throughout a warm reset
- SYSBOOT pins are not latched with a warm reset. The device will boot with the SYSBOOT values from the previous cold reset.
- Most debug subsystem logic is not affected by warm reset. This allows you to maintain any debug sessions throughout a warm reset event.
- PLLs are not affected by warm reset

As an output, nRESETIN_OUT can be used to reset external devices. nRESET_OUT will drive low during a cold reset or an internally generated warm reset. After completion of a cold or warm reset, nRESETIN_OUT will continue to drive low for a period defined by PRM_RSTTIME.RSTTIME1. RSTTIME1 is a timer that counts down to zero at a rate equal to the high frequency system input clock SYS_CLK. This allows external devices to be held in reset for some time after the AM335x comes out of reset.

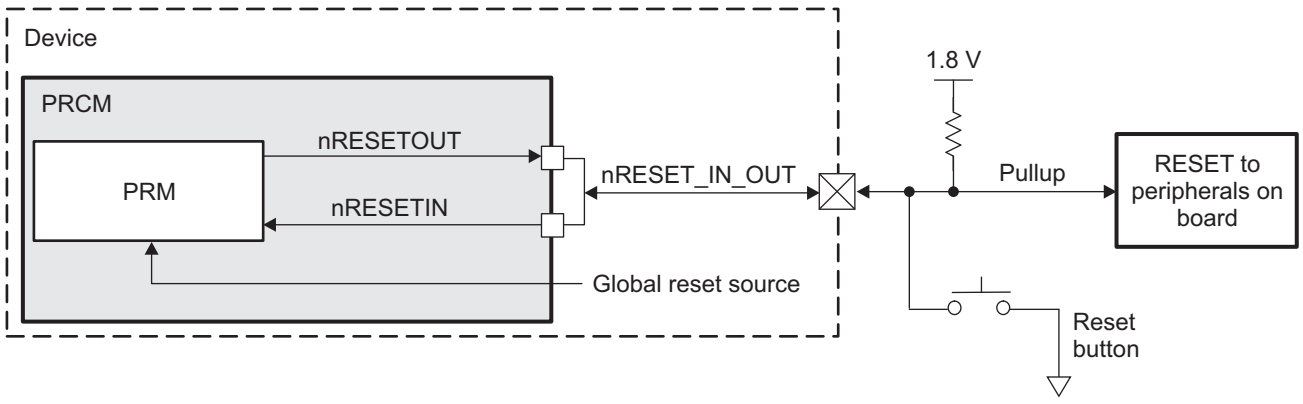
Caution must be used when implementing the nRESETIN_OUT as an bi-directional reset signal. Because of the short maximum time allowed using RSTTIME1, it does not supply an adequate debounce time for an external push button circuit. The processor could potentially start running while external components are still in reset. It is recommended that this signal be used as input only (do not connect to other devices as a reset) to implement a push button reset circuit to the AM335x, or an output only to be able to reset other devices after an AM335x reset completes.

8.1.1.7.4.1.1 Warm Reset Input/Reset Output (nRESETIN_OUT)

Any global reset source (internal or external) causes nRESETIN_OUT to be driven and maintained at the boundary of the device for at least the amount of time configured in the PRCM.PRM_RSTTIME. RSTTIME1 bit field. This ensures that the device and its related peripherals are reset together. The nRESETIN_OUT output buffer is configured as an open-drain; consequently, an external pull-up resistor is required.

After the de-assertion, the bi-directional pin nRESETIN_OUT is tri-stated to allow for assertion from off chip source (externally).

Figure 8-19. External System Reset



Copyright © 2011, Texas Instruments Incorporated

The device will have one pin nRESETIN_OUT which reflects chip reset status. This output will always assert asynchronously when any chip watchdog timer reset occurs if any of the following reset events occurs:

- POR (only internal stretched portion of reset event after bootstrap is latched)
- External Warm reset (nRESETIN_OUT pin, only internal stretched portion of reset event after bootstrap is latched)
- Emulation reset (Cold or warm from ICEPICK)
- Reset requestor
- SW cold/warm reset

This output will remain asserted as long as PRCM keeps reset to the host processor asserted.

Note: TRST does not cause RSTOUTn assertion

8.1.1.7.4.1.2 Warm Reset Sequence

1. nRESETIN_OUT pin at chip boundary gets asserted (goes low). NOTE: For Warm Reset sequence to work as described, it is expected that PORz pin is always inactive, otherwise you will get PORz functionality as described in previous section.
2. All IOs (except test and emulation) will go to tri-state immediately.
3. Chip clocks are not affected as both PLL and dividers are intact.
4. nRESETIN_OUT gets de-asserted after 30 cycles
5. PRCM de-asserts reset to the host processor and all other peripherals without local CPUs.
6. Note that all IPs with local CPUs will have local reset asserted by default at Warm Reset and reset de-assertion would require host processor to write to respective registers in PRCM.

Figure 8-20 shows the nRESETIN_OUT waveform when using nRESETIN_OUT as warm reset source. For the duration when external warm reset switch is closed, both the device and chip will be driving zero.

Figure 8-20. nRESETIN_OUT Waveform as Warm Reset Source

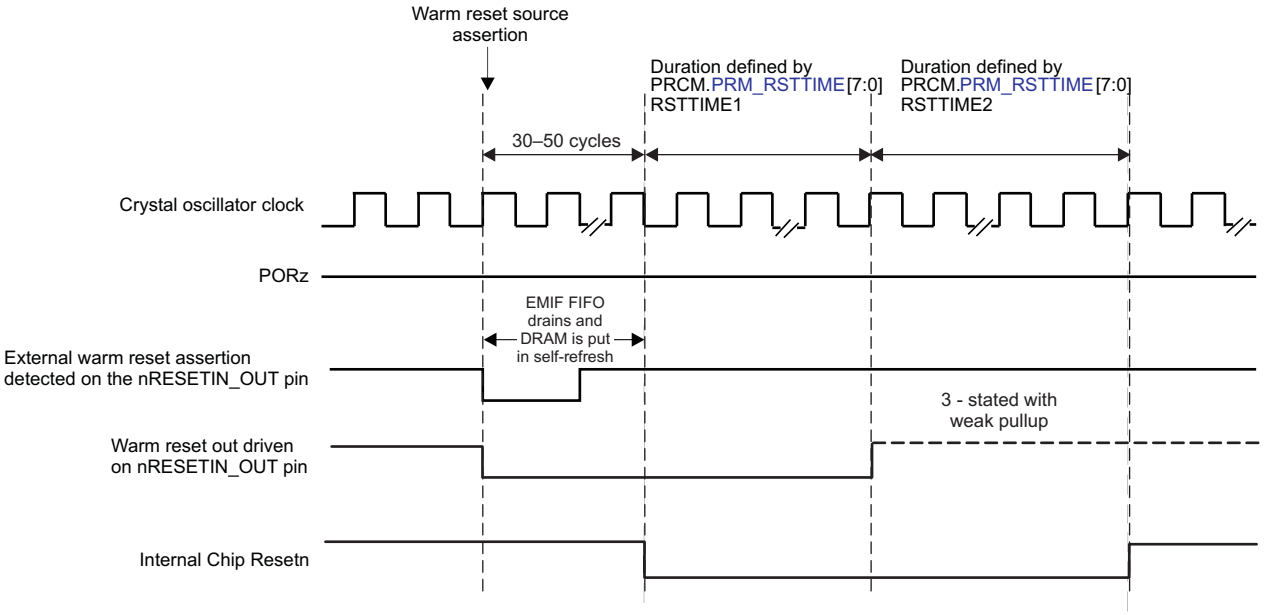


Figure 8-21 shows the nRESETIN_OUT waveform when any one of the warm reset sources captured except using nRESETIN_OUT itself as warm reset source.

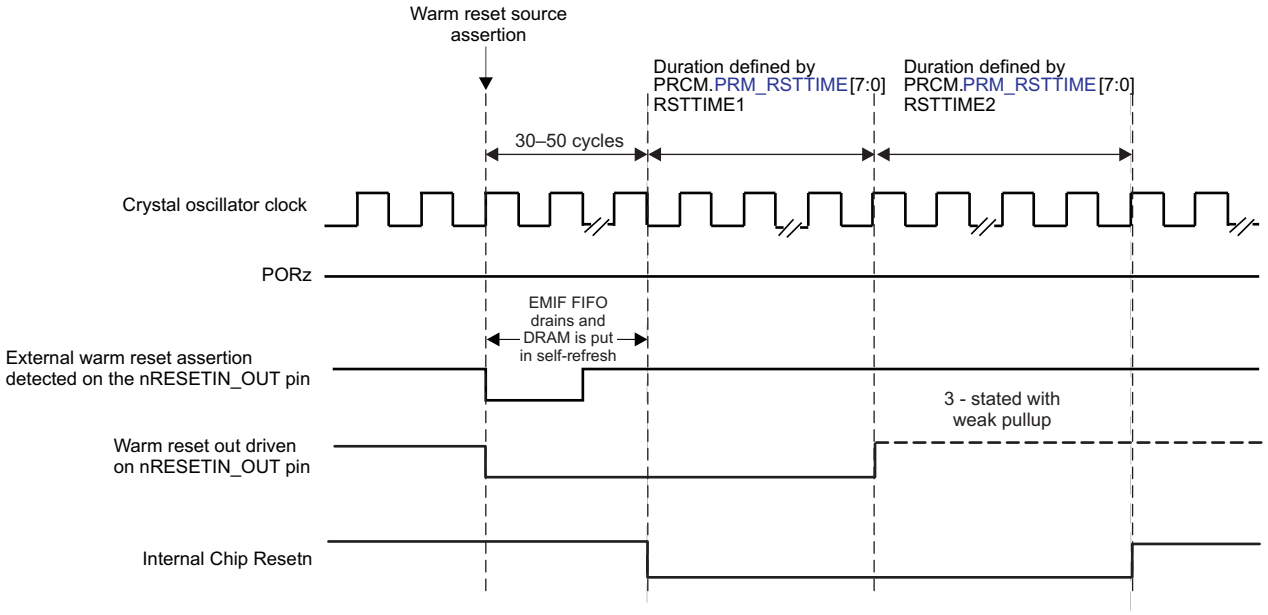
Copyright © 2011, Texas Instruments Incorporated

Figure 8-21. nRESETIN_OUT Waveform Not as Warm Reset Source



8.1.1.7.4.2 Watchdog Timer

There is one watchdog timer on the device. The reset is not blockable.

8.1.1.7.4.3 Global Warm Software Reset (GLOBAL_SW_WARM_RST)

8.1.1.7.4.4 Test Reset (TRSTz)

This reset is triggered from TRSTz pin on JTAG interface. This is a non-blockable reset and it resets test and emulation logic.

NOTE: A PORz reset assertion should cause entire device to reset including all test and emulation logic regardless of the state of TRSTz Therefore, PORz assertion will achieve full reset of the device even if TRSTz pin is pulled permanently high and no special toggling of TRSTz pin is required during power ramp to achieve full POR reset to the device. Further, it is acceptable for TRSTz input to be pulled permanently low during normal functional usage of the device in the end-system to ensure that all test and emulation logic is kept in reset.

Copyright © 2011, Texas Instruments Incorporated

8.1.1.7.5 Reset Characteristics

The following table shows characteristic of each reset source.

Copyright © 2011, Texas Instruments Incorporated

Table 8-24. Reset Sources

	Cold Reset Sources			Warm Reset sources			
Characteristic	Pin PORz	SW Cold Reset	Bad Device	Pin Warm Reset	Watchdog Timer	SW Warm Reset	TRSTz
Boot pins latched	Y	N	N	N	N	N	N
Resets Standard Efuses	Y	N	N	N	N	N	N
Resets Customer Efuses	Y	Y	Y	Y	Y	Y	N
DRAM contents preserved	N	N	N	Y(1)	Y(1)	Y(1)	Y
Resets PLLs(2)	Y	Y	Y	N	N	N	N
Resets Clock Dividers(2)	Y	Y	Y	N	N	N	N
PLLs enter bypass mode(2)	Y	Y	Y	Y	Y	Y	N
Reset source blockable by emulation	N	N	N	Y	Y	Y	Y
Resets test and emulation logic	Y	Y	Y	N	N	N	N
Resets GMAC switch and related chip logic	Y	N(3)	Y	N(3)	N(3)	N(3)	
Resets Chip Functional Logic(4)	Y	Y	Y	Y	Y	Y	N
Puts IOs in Tri-state	Y	Y	Y	Y	Y	Y	N
Resets Pinmux Registers	Y	Y	Y(5)	Y(5)	Y(5)	Y(5)	N
Reset out Assertion (nRESETIN_OUT Pin)	Y	Y	Y(5)	Y(5)	Y(5)	Y(5)	N
Resets RTC	N	N	N	N	N	N	N

(1) The ROM software does not utilize this feature of DRAM content preservation. Hence, the AM335x re-boots like a cold boot for warm reset as well.
(2) CORE PLL is an exception when EMAC switch reset isolation is enabled
(3) Only true if GMAC switch reset isolation is enabled in control registers, otherwise will be reset.
(4) There are exception details in control module & PRCM registers which are captured in the register specifications in Chapter 8 and Chapter 9. This includes some pinmux registers which are warm reset in-sensitive.
(5) Some special IOs/Muxing registers like test, emulation, GEMAC Switch (When under reset isolation mode), etc related will not be affected under warm reset conditions.

Copyright © 2011, Texas Instruments Incorporated

Note: The Bandgap macros for the LDOs will be reset on PORz only.

8.1.1.7.6 EMAC Switch Reset Isolation

The device will support reset isolation for the Ethernet Switch IP. This allows the device to undergo a warm reset without disrupting the switch or traffic being routed through the switch during the reset condition.

If configured by registers in control module that EMAC reset isolation is active, then behavior is as follows:

Any “Warm” reset source(except the software warm reset) will be blocked to the EMAC switch logic in the IP (the IP has two reset inputs to support such isolation) and to PLL (and it’s control bits) which is sourcing the EMAC switch clocks as required by the IP (50- or 125-MHz reference clocks). Also, the EMAC switch related IO pins must retain their pin muxing and not glitch (continuously controlled by the EMAC switch IP) by blocking reset to the controlling register bits.

If configured by registers in control module that EMAC reset isolation is NOT active (default state), then the warm reset sources are allowed to propagate as normal including to the EMAC Switch IP (both reset inputs to the IP).

All cold or POR resets will always propagate to the EMAC switch IP as normal (as otherwise defined in this document).

8.1.1.7.7 Reset Priority

If more than one of these reset sources are asserted simultaneously then the following priority order should be used:

1. POR
2. TRSTz
3. External warm reset
4. Emulation
5. Reset requestors
6. Software resets

8.1.1.7.8 Trace Functionality Across Reset

Other than POR, TRSTz and SW cold reset, none of the other resets will affect trace functionality. This requires that Debug_SS has required reset isolation for the trace logic. Also the Ios and muxing control (if any) for trace Ios should not get affected by any other reset. Since none of the PLLs getting reset with other resets, clocks will be any way stable.

8.1.1.7.9 RTC PORz

AM335x supports RTC only mode by supplying dedicated power to RTC module. The RTC module has a dedicated PORz signal (RTC_PORz) to reset RTC logic and circuitry during powerup. RTC_PORz is expected to be driven low when the RTC power supply is ramping up. After the power supply reaches its stable value, the RTC_PORz can be de-asserted. The RTC module is not affected by the device PORz. Similarly RTC_PORz does not affect the device reset.

If the RTC-only mode is not required, then PORz and RTC_PORz needs to be shorted. For power-up sequencing with respect to RTC_PORz, see the device specific datasheet.

Copyright © 2011, Texas Instruments Incorporated

8.1.1.8 Power-Up/Down Sequence

Each power domain has dedicated warm and cold reset.

Warm reset gets asserted each time there is any warm reset source requesting reset. Warm reset is also asserted when power domain moves from ON to OFF state.

Cold reset for the domain is asserted in response to cold reset sources. When domain moves from OFF to ON state then also cold reset gets asserted as this is similar to power-up condition for that domain.

8.1.1.9 IO State

All IOs except for JTAG i/f and Reset output (and any special cases mentioned in pinlist) should have their output drivers tri-state and internal pulls enabled during assertion of all reset sources. JTAG i/f IO is affected only by TRSTz.

Note: The PRUs and Cortex M3 processor are held under reset after global warm reset by assertion of software source of reset. Other domains are held under reset after global warm reset until the MPU software enables their respective interface clock.

8.1.1.10 Voltage and Power Domains

The following table shows how the device core logic is partitioned into two core logic voltage domains and four power domains. The table lists which voltage and power domain a functional module belongs.

Copyright © 2011, Texas Instruments Incorporated

Table 8-25. Core Logic Voltage and Power Domains

Logic Voltage Domain Name	Module
CORE	All Core Modules
RTC	RTC

8.1.1.10.1 Voltage Domains

The core logic is divided into two voltage domains: VDD_CORE and VDD_RTC.

8.1.1.10.2 Power Domains

In order to reduce power due to leakage, the core logic supply voltage to 4 of these power domains can be turned OFF with internal power switches. The internal power switches are controlled through memory mapped registers in Control Module.

In a use case whereby all the modules within a power domain are not used that power domain can be placed in the OFF state.

Error: Reference source not found shows the allowable combination power domain ON/OFF states and which power domains are switched via internal power switches. At power-on-reset, all domains except always-on will be in the power domain OFF state.

8.1.1.11.1 Power Domain Power Down Sequence

The following sequence of steps happen during the power down of a power domain

All IPs (belonging to a power domain) with STANDBY interface will assert STANDBY. STANDBY assertion should get triggered by IP based on its activity on OCP initiator port. IP should assert STANDBY whenever initiator port is IDLE. Some of the IPs may not have this feature and they will require SW write to standby-mode register to get STANDBY assertion from IP.

1. SW will request all modules in given power domain to go to disable state by programming module control register inside PRCM.
2. PRCM will start and wait for completion of power management handshake with IPs (IdleReq/IdleAck).
3. PRCM will gate-off all the clocks to the power domain.
4. SW will request all clock domains in given power domain to go to “force sleep” mode by programming functional clock domain register in PRCM. Note that PRCM has already gated-off clocks and this register programming may look redundant.
5. SW will request PRCM to take this power domain to OFF state by programming PWRSTCTRL register. Note that this step can be skipped if PWRSTCTRL is permanently programmed to OFF state. When this is done, functional clock domain register decides when power domain will be taken to OFF state. Only reason not to have OFF state in PWRSTCTRL is to take power domain to just clock gate state without power gating.
6. PSCON specific to this power domain will assert isolation enable for the domain.
7. PRCM will assert warm and cold reset to the power domain.
8. PSCON will assert control signals to switch-off power using on-die switches.
9. On-die switches will send acknowledge back to PSCON.

8.1.1.11.2 Power Domain Power-Up Sequence

The following sequence of steps occurs during power-up of a power domain. This sequence is not relevant to always-on domain as this domain will never go to OFF state as long as the device is powered. This sequence will be repeated each time a domain is taken to ON state from OFF (including first time power-up). Note that some of the details are intentionally taken out here to simplify things.

There can be multiple reasons to start power-up sequence for a domain. For example it can be due to an interrupt from one of the IPs which is powered-up.

1. SW will request required clock domains inside this power domain to go to force wake-up state by programming functional clock domain register.
2. PRCM will enable clocks to the required clock domains.
3. PSCON specific to this power domain will assert control signal to un-gate the power.
4. Once power is un-gated, on die switches will send acknowledge back to PSCON.
5. PRCM will de-assert cold and warm reset to the power domain.
6. PRCM will turn-off isolation cells.
7. SW will request PRCM to enable required module in the power domain by programming module control register.
8. PRCM will initiate and wait for completion of PM protocol to enable the modules (IdleReq/IdleAck).

Bit	Field	Type	Reset	Description
31-8	Reserved	R	0h	
7	CLKACTIVITY_MCASP_GCLK	R	0h	This field indicates the state of the MCASP_GCLK clock in the domain. 0 = Inact 1 = Act
6	CLKACTIVITY_CPTS_RFT_GCLK	R	0h	This field indicates the state of the CLKACTIVITY_CPTS_RFT_GCLK clock in the domain. 0 = Inact 1 = Act
5	Reserved	R	0h	
4	CLKACTIVITY_L3_GCLK	R	1h	This field indicates the state of the L3_GCLK clock in the domain. 0 = Inact 1 = Act
3	CLKACTIVITY_MMC_FCLK	R	0h	This field indicates the state of the MMC_GCLK clock in the domain. 0 = Inact 1 = Act
2	CLKACTIVITY_EMIF_GCLK	R	0h	This field indicates the state of the EMIF_GCLK clock in the domain. 0 = Inact 1 = Act
1-0	CLKTRCTRL	R/W	2h	Controls the clock state transition of the L3 clock domain. 0 = NO_SLEEP : NO_SLEEP: Sleep transition cannot be initiated. Wakeup transition may however occur. 1 = SW_SLEEP : SW_SLEEP: Start a software forced sleep transition on the domain. 2 = SW_WKUP : SW_WKUP: Start a software forced wake-up transition on the domain. 3 = HW_AUTO : HW_AUTO: Automatic transition is enabled. Sleep and wakeup transition are based upon hardware conditions.

8.1.2.1.4 CM_PER_CPGMAC0_CLKCTRL Register (offset = 14h) [reset = 70000h]

CM_PER_CPGMAC0_CLKCTRL is shown in Figure 8-25 and described in Table 8-32.

This register manages the CPSW clocks.

Figure 8-25. CM_PER_CPGMAC0_CLKCTRL Register

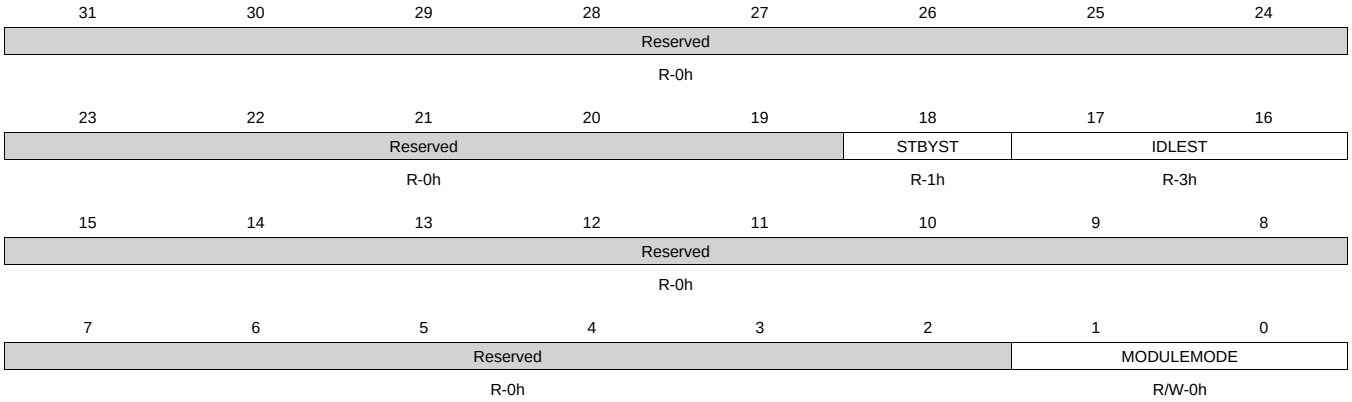

Table 8-32. CM_PER_CPGMAC0_CLKCTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-19	Reserved	R	0h	
18	STBYST	R	1h	Module standby status. This bit is warm reset insensitive when CPSW RESET_ISO is enabled 0 = Func : Module is functional (not in standby) 1 = Standby : Module is in standby
17-16	IDLEST	R	3h	Module idle status. This bit is warm reset insensitive when CPSW RESET_ISO is enabled 0 = Func : Module is fully functional, including OCP 1 = Trans : Module is performing transition: wakeup, or sleep, or sleep abortion 2 = Idle : Module is in Idle mode (only OCP part). It is functional if using separate functional clock 3 = Disable : Module is disabled and cannot be accessed
15-2	Reserved	R	0h	
1-0	MODULEMODE	R/W	0h	Control the way mandatory clocks are managed. This bit is warm reset insensitive when CPSW RESET_ISO is enabled 0 = DISABLED : Module is disable by SW. Any OCP access to module results in an error, except if resulting from a module wakeup (asynchronous wakeup). 1 = RESERVED_1 : Reserved 2 = ENABLE : Module is explicitly enabled. Interface clock (if not used for functions) may be gated according to the clock domain state. Functional clocks are guarantied to stay present. As long as in this configuration, power domain sleep transition cannot happen. 3 = RESERVED : Reserved

8.1.2.1.21 CM_PER_MCASP1_CLKCTRL Register (offset = 68h) [reset = 30000h]

CM_PER_MCASP1_CLKCTRL is shown in Figure 8-42 and described in Table 8-49.

This register manages the MCASP1 clocks.

Figure 8-42. CM_PER_MCASP1_CLKCTRL Register

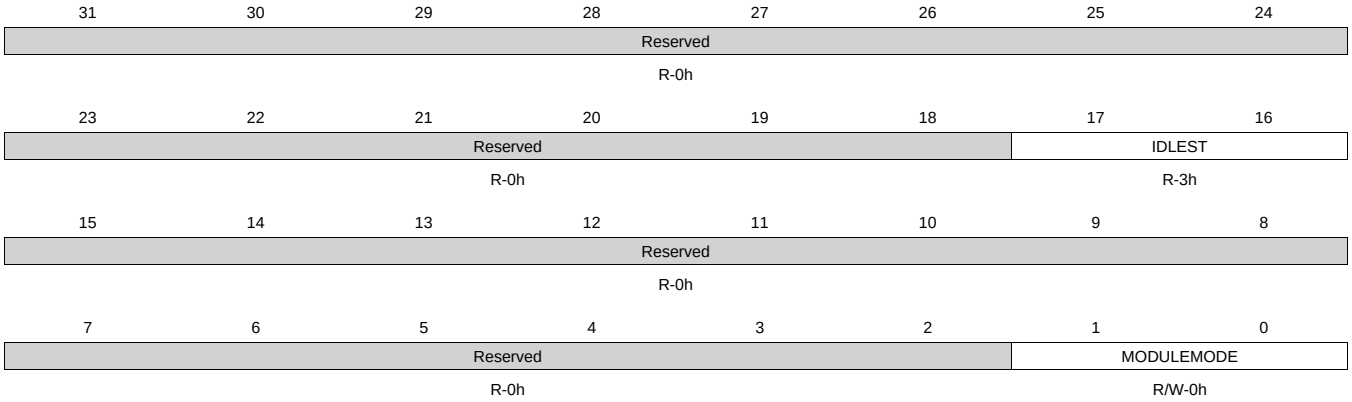

Table 8-49. CM_PER_MCASP1_CLKCTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-18	Reserved	R	0h	
17-16	IDLEST	R	3h	Module idle status. 0 = Func : Module is fully functional, including OCP 1 = Trans : Module is performing transition: wakeup, or sleep, or sleep abortion 2 = Idle : Module is in Idle mode (only OCP part). It is functional if using separate functional clock 3 = Disable : Module is disabled and cannot be accessed
15-2	Reserved	R	0h	
1-0	MODULEMODE	R/W	0h	Control the way mandatory clocks are managed. 0 = DISABLED : Module is disable by SW. Any OCP access to module results in an error, except if resulting from a module wakeup (asynchronous wakeup). 1 = RESERVED_1 : Reserved 2 = ENABLE : Module is explicitly enabled. Interface clock (if not used for functions) may be gated according to the clock domain state. Functional clocks are guarantied to stay present. As long as in this configuration, power domain sleep transition cannot happen. 3 = RESERVED : Reserved

Table 8-89. CM_WKUP_CLKSTCTRL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	CLKACTIVITY_SR_SYSCLK	R	0h	This field indicates the state of the SMARTREFGLEX SYSCLK clock in the domain. 0 = Inact : Corresponding clock is gated 1 = Act : Corresponding clock is active
2	CLKACTIVITY_L4_WKUP_GCLK	R	1h	This field indicates the state of the L4_WKUP clock in the domain. 0 = Inact : Corresponding clock is gated 1 = Act : Corresponding clock is active
1-0	CLKTRCTRL	R/W	2h	Controls the clock state transition of the always on clock domain. 0 = NO_SLEEP : NO_SLEEP: Sleep transition cannot be initiated. Wakeup transition may however occur. 1 = SW_SLEEP : SW_SLEEP: Start a software forced sleep transition on the domain. 2 = SW_WKUP : SW_WKUP: Start a software forced wake-up transition on the domain. 3 = HW_AUTO : HW_AUTO: Automatic transition is enabled. Sleep and wakeup transition are based upon hardware conditions.

8.1.2.2.2 CM_WKUP_CONTROL_CLKCTRL Register (offset = 4h) [reset = 30000h]

CM_WKUP_CONTROL_CLKCTRL is shown in Figure 8-82 and described in Table 8-90.

This register manages the Control Module clocks.

Figure 8-82. CM_WKUP_CONTROL_CLKCTRL Register

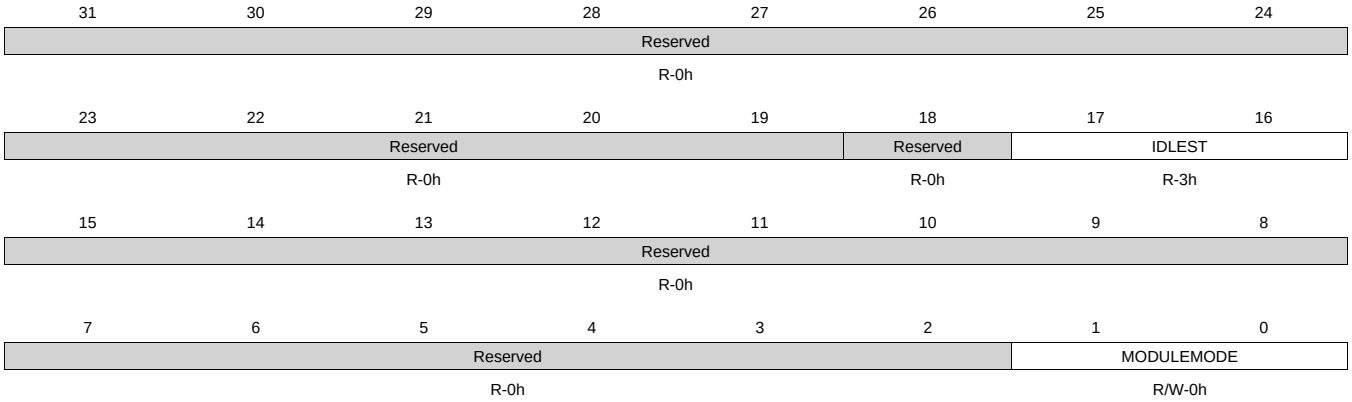

Table 8-90. CM_WKUP_CONTROL_CLKCTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-19	Reserved	R	0h	
18	Reserved	R	0h	
17-16	IDLEST	R	3h	Module idle status. 0 = Func : Module is fully functional, including OCP 1 = Trans : Module is performing transition: wakeup, or sleep, or sleep abortion 2 = Idle : Module is in Idle mode (only OCP part). It is functional if using separate functional clock 3 = Disable : Module is disabled and cannot be accessed
15-2	Reserved	R	0h	
1-0	MODULEMODE	R/W	0h	Control the way mandatory clocks are managed. 0 = DISABLED : Module is disable by SW. Any OCP access to module results in an error, except if resulting from a module wakeup (asynchronous wakeup). 1 = RESERVED_1 : Reserved 2 = ENABLE : Module is explicitly enabled. Interface clock (if not used for functions) may be gated according to the clock domain state. Functional clocks are guarantied to stay present. As long as in this configuration, power domain sleep transition cannot happen. 3 = RESERVED : Reserved

Bit	Field	Type	Reset	Description
31-13	Reserved	R	0h	
12	HSDIVIDER_CLKOUT2_PWDN	R/W	0h	Automatic power down for HSDIVIDER M5 divider and hence CLKOUT2 output when the o/p clock is gated. 0 = ALWAYS_ACTIVE : Keep M5 divider powered on even when CLKOUT2 is gated. 1 = AUTO_PWDN : Automatically power down M5 divider when CLKOUT2 is gated.
11-10	Reserved	R	0h	
9	ST_HSDIVIDER_CLKOUT2	R	0h	HSDIVIDER CLKOUT2 status 0 = CLK_ENABLED : The clock output is enabled 1 = CLK_GATED : The clock output is gated
8	HSDIVIDER_CLKOUT2_GATE_CTRL	R/W	0h	Control gating of HSDIVIDER CLKOUT2 0 = CLK_AUTOGATE : Automatically gate this clock when there is no dependency for it 1 = CLK_ENABLE : Force this clock to stay enabled even if there is no request
7-6	Reserved	R	0h	
5	HSDIVIDER_CLKOUT2_DIVCHACK	R	0h	Toggle on this status bit after changing HSDIVIDER_CLKOUT2_DIV indicates that the change in divider value has taken effect
4-0	HSDIVIDER_CLKOUT2_DIV	R/W	4h	DPLL post-divider factor, M5, for internal clock generation. Divide values from 1 to 31.

8.1.3.1.4 PRM_IRQSTATUS_M3 Register (offset = Ch) [reset = 0h]

This register provides status on MPU interrupt events. An event is logged whether interrupt generation for the event is enabled or not. SW is required to clear a set bit by writing a '1' into the bit-position to be cleared.

PRM_IRQSTATUS_M3 is shown in Figure 8-164 and described in Table 8-179.

8.1.3.1.5 PRM_IRQENABLE_M3 Register (offset = 10h) [reset = 0h]

This register is used to enable and disable events used to trigger MPU interrupt activation.

PRM_IRQENABLE_M3 is shown in Figure 8-165 and described in Table 8-180.
