LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 16-226. RXGCR13 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	RX_ENABLE	R/W	0h	This field enables or disables the channel 0 = channel is disabled 1 = channel is enabled This field will be cleared after a channel teardown is complete.
30	RX_TEARDOWN	R/W	0h	This field indicates whether or not an Rx teardown operation is complete. This field should be cleared when a channel is initialized. This field will be set after a channel teardown is complete.
29	RX_PAUSE	R/W	0h	Setting this bit causes the CPPI DMA to be suspended for rx channels. If a pause is being requested and the channel is not in a packet then drop the credit.
24	RX_ERROR_HANDLING	W	0h	This bit controls the error handling mode for the channel and is only used when channel errors (i.e. descriptor or buffer starvation occurs): 0 = Starvation errors result in dropping packet and reclaiming any used descriptor or buffer resources back to the original queues/pools they were allocated to 1 = Starvation errors result in subsequent re-try of the descriptor allocation operation. In this mode, the DMA will return to the IDLE state without saving it's internal operational state back to the internal state RAM and without issuing an advance operation on the FIFO interface. This results in the DMA re-initiating the FIFO block transfer at a later time with the intention that additional free buffers and/or descriptors will have been added. Regardless of the value of this bit, the DMA will assert the cdma_rx_sof_overrun (for SOP) or cdma_rx_mof_overrun (for non-SOP) when
23-16	RX_SOP_OFFSET	W	0h	This field specifies the number of bytes that are to be skipped in the SOP buffer before beginning to write the payload. This value must be less than the minimum size of a buffer in the system. Valid values are 0 - 255 bytes.
15-14	RX_DEFAULT_DESC_TYPE	W	0h	This field indicates the default descriptor type to use: 0 = Reserved 1 = Host 2 = Reserved 3 = Reserved The actual descriptor type that will be used for reception can be overridden by information provided in the CPPI FIFO data block.

Table 16-238. RXGCR16 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	RX_ENABLE	R/W	0h	This field enables or disables the channel 0 = channel is disabled 1 = channel is enabled This field will be cleared after a channel teardown is complete.
30	RX_TEARDOWN	R/W	0h	This field indicates whether or not an Rx teardown operation is complete. This field should be cleared when a channel is initialized. This field will be set after a channel teardown is complete.
29	RX_PAUSE	R/W	0h	Setting this bit causes the CPPI DMA to be suspended for rx channels. If a pause is being requested and the channel is not in a packet then drop the credit.
24	RX_ERROR_HANDLING	W	0h	This bit controls the error handling mode for the channel and is only used when channel errors (i.e. descriptor or buffer starvation occurs): 0 = Starvation errors result in dropping packet and reclaiming any used descriptor or buffer resources back to the original queues/pools they were allocated to 1 = Starvation errors result in subsequent re-try of the descriptor allocation operation. In this mode, the DMA will return to the IDLE state without saving it's internal operational state back to the internal state RAM and without issuing an advance operation on the FIFO interface. This results in the DMA re-initiating the FIFO block transfer at a later time with the intention that additional free buffers and/or descriptors will have been added. Regardless of the value of this bit, the DMA will assert the cdma_rx_sof_overrun (for SOP) or cdma_rx_mof_overrun (for non-SOP) when
23-16	RX_SOP_OFFSET	W	0h	This field specifies the number of bytes that are to be skipped in the SOP buffer before beginning to write the payload. This value must be less than the minimum size of a buffer in the system. Valid values are 0 - 255 bytes.
15-14	RX_DEFAULT_DESC_TYPE	W	0h	This field indicates the default descriptor type to use: 0 = Reserved 1 = Host 2 = Reserved 3 = Reserved The actual descriptor type that will be used for reception can be overridden by information provided in the CPPI FIFO data block.

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 16-250. RXGCR19 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	RX_ENABLE	R/W	0h	This field enables or disables the channel 0 = channel is disabled 1 = channel is enabled This field will be cleared after a channel teardown is complete.
30	RX_TEARDOWN	R/W	0h	This field indicates whether or not an Rx teardown operation is complete. This field should be cleared when a channel is initialized. This field will be set after a channel teardown is complete.
29	RX_PAUSE	R/W	0h	Setting this bit causes the CPPI DMA to be suspended for rx channels. If a pause is being requested and the channel is not in a packet then drop the credit.
24	RX_ERROR_HANDLING	W	0h	This bit controls the error handling mode for the channel and is only used when channel errors (i.e. descriptor or buffer starvation occurs): 0 = Starvation errors result in dropping packet and reclaiming any used descriptor or buffer resources back to the original queues/pools they were allocated to 1 = Starvation errors result in subsequent re-try of the descriptor allocation operation. In this mode, the DMA will return to the IDLE state without saving it's internal operational state back to the internal state RAM and without issuing an advance operation on the FIFO interface. This results in the DMA re-initiating the FIFO block transfer at a later time with the intention that additional free buffers and/or descriptors will have been added. Regardless of the value of this bit, the DMA will assert the cdma_rx_sof_overrun (for SOP) or cdma_rx_mof_overrun (for non-SOP) when
23-16	RX_SOP_OFFSET	W	0h	This field specifies the number of bytes that are to be skipped in the SOP buffer before beginning to write the payload. This value must be less than the minimum size of a buffer in the system. Valid values are 0 - 255 bytes.
15-14	RX_DEFAULT_DESC_TYPE	W	0h	This field indicates the default descriptor type to use: 0 = Reserved 1 = Host 2 = Reserved 3 = Reserved The actual descriptor type that will be used for reception can be overridden by information provided in the CPPI FIFO data block.

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 16-262. RXGCR22 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	RX_ENABLE	R/W	0h	This field enables or disables the channel 0 = channel is disabled 1 = channel is enabled This field will be cleared after a channel teardown is complete.
30	RX_TEARDOWN	R/W	0h	This field indicates whether or not an Rx teardown operation is complete. This field should be cleared when a channel is initialized. This field will be set after a channel teardown is complete.
29	RX_PAUSE	R/W	0h	Setting this bit causes the CPPI DMA to be suspended for rx channels. If a pause is being requested and the channel is not in a packet then drop the credit.
24	RX_ERROR_HANDLING	W	0h	This bit controls the error handling mode for the channel and is only used when channel errors (i.e. descriptor or buffer starvation occurs): 0 = Starvation errors result in dropping packet and reclaiming any used descriptor or buffer resources back to the original queues/pools they were allocated to 1 = Starvation errors result in subsequent re-try of the descriptor allocation operation. In this mode, the DMA will return to the IDLE state without saving it's internal operational state back to the internal state RAM and without issuing an advance operation on the FIFO interface. This results in the DMA re-initiating the FIFO block transfer at a later time with the intention that additional free buffers and/or descriptors will have been added. Regardless of the value of this bit, the DMA will assert the cdma_rx_sof_overrun (for SOP) or cdma_rx_mof_overrun (for non-SOP) when
23-16	RX_SOP_OFFSET	W	0h	This field specifies the number of bytes that are to be skipped in the SOP buffer before beginning to write the payload. This value must be less than the minimum size of a buffer in the system. Valid values are 0 - 255 bytes.
15-14	RX_DEFAULT_DESC_TYPE	W	0h	This field indicates the default descriptor type to use: 0 = Reserved 1 = Host 2 = Reserved 3 = Reserved The actual descriptor type that will be used for reception can be overridden by information provided in the CPPI FIFO data block.

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 16-274. RXGCR25 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	RX_ENABLE	R/W	0h	This field enables or disables the channel 0 = channel is disabled 1 = channel is enabled This field will be cleared after a channel teardown is complete.
30	RX_TEARDOWN	R/W	0h	This field indicates whether or not an Rx teardown operation is complete. This field should be cleared when a channel is initialized. This field will be set after a channel teardown is complete.
29	RX_PAUSE	R/W	0h	Setting this bit causes the CPPI DMA to be suspended for rx channels. If a pause is being requested and the channel is not in a packet then drop the credit.
24	RX_ERROR_HANDLING	W	0h	This bit controls the error handling mode for the channel and is only used when channel errors (i.e. descriptor or buffer starvation occurs): 0 = Starvation errors result in dropping packet and reclaiming any used descriptor or buffer resources back to the original queues/pools they were allocated to 1 = Starvation errors result in subsequent re-try of the descriptor allocation operation. In this mode, the DMA will return to the IDLE state without saving it's internal operational state back to the internal state RAM and without issuing an advance operation on the FIFO interface. This results in the DMA re-initiating the FIFO block transfer at a later time with the intention that additional free buffers and/or descriptors will have been added. Regardless of the value of this bit, the DMA will assert the cdma_rx_sof_overrun (for SOP) or cdma_rx_mof_overrun (for non-SOP) when
23-16	RX_SOP_OFFSET	W	0h	This field specifies the number of bytes that are to be skipped in the SOP buffer before beginning to write the payload. This value must be less than the minimum size of a buffer in the system. Valid values are 0 - 255 bytes.
15-14	RX_DEFAULT_DESC_TYPE	W	0h	This field indicates the default descriptor type to use: 0 = Reserved 1 = Host 2 = Reserved 3 = Reserved The actual descriptor type that will be used for reception can be overridden by information provided in the CPPI FIFO data block.

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 16-286. RXGCR28 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	RX_ENABLE	R/W	0h	This field enables or disables the channel 0 = channel is disabled 1 = channel is enabled This field will be cleared after a channel teardown is complete.
30	RX_TEARDOWN	R/W	0h	This field indicates whether or not an Rx teardown operation is complete. This field should be cleared when a channel is initialized. This field will be set after a channel teardown is complete.
29	RX_PAUSE	R/W	0h	Setting this bit causes the CPPI DMA to be suspended for rx channels. If a pause is being requested and the channel is not in a packet then drop the credit.
24	RX_ERROR_HANDLING	W	0h	This bit controls the error handling mode for the channel and is only used when channel errors (i.e. descriptor or buffer starvation occurs): 0 = Starvation errors result in dropping packet and reclaiming any used descriptor or buffer resources back to the original queues/pools they were allocated to 1 = Starvation errors result in subsequent re-try of the descriptor allocation operation. In this mode, the DMA will return to the IDLE state without saving it's internal operational state back to the internal state RAM and without issuing an advance operation on the FIFO interface. This results in the DMA re-initiating the FIFO block transfer at a later time with the intention that additional free buffers and/or descriptors will have been added. Regardless of the value of this bit, the DMA will assert the cdma_rx_sof_overrun (for SOP) or cdma_rx_mof_overrun (for non-SOP) when
23-16	RX_SOP_OFFSET	W	0h	This field specifies the number of bytes that are to be skipped in the SOP buffer before beginning to write the payload. This value must be less than the minimum size of a buffer in the system. Valid values are 0 - 255 bytes.
15-14	RX_DEFAULT_DESC_TYPE	W	0h	This field indicates the default descriptor type to use: 0 = Reserved 1 = Host 2 = Reserved 3 = Reserved The actual descriptor type that will be used for reception can be overridden by information provided in the CPPI FIFO data block.

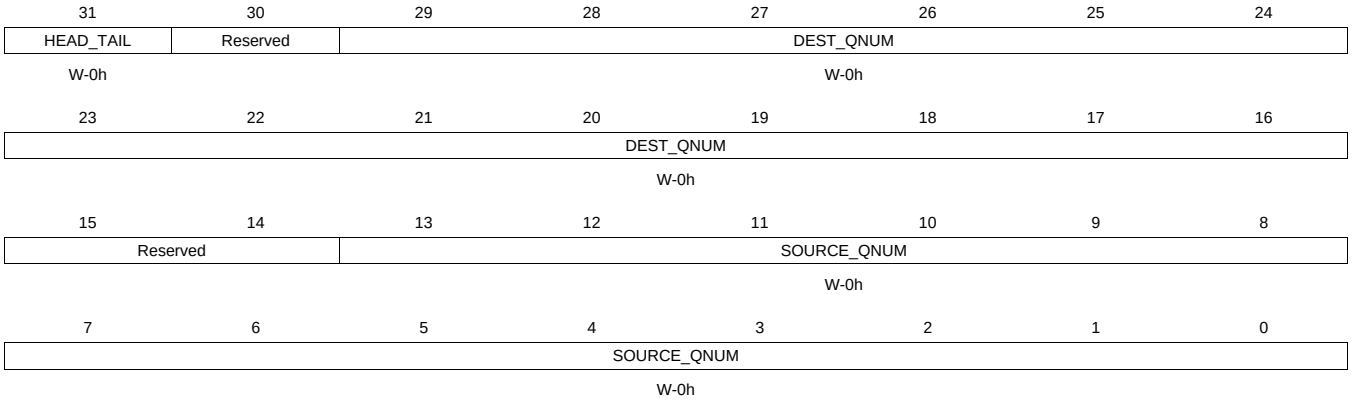
16.11.2 QMGRRST Register (offset = 8h) [reset = 0h]

QMGRRST is shown in Figure 16-345 and described in Table 16-359.

Figure 16-345. QMGRRST Register



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 16-359. QMGRRST Register Field Descriptions

Bit	Field	Type	Reset	Description
31	HEAD_TAIL	W	0h	Indicates whether queue contents should be merged on to head or tail of destination queue. Clear this field for head and set for tail.
29-16	DEST_QNUM	W	0h	Destination Queue Number
13-0	SOURCE_QNUM	W	0h	Source Queue Number Queue Manager Queue Diversion Register Note : CBA write transactions to this register cause the QMGR to start processing an internal state machine. This disables CBA read transactions.while it is busy processing the state machine. Once the state machine is back in the idle state CBA read transactions are available again.

Table 16-377. QMEMCTRL0 Register Field Descriptions

Bit	Field	Type	Reset	Description
29-16	START_INDEX	R/W	0h	This field indicates where in linking RAM does the descriptor linking information corresponding to memory region R starts.
11-8	DESC_SIZE	R/W	0h	This field indicates the size of each descriptor in this memory region. It is an encoded value that specifies descriptor size as 2^(5+desc_size) number of bytes. The settings of desc_size from 9-15 are reserved.
2-0	REG_SIZE	R/W	0h	This field indicates the size of the memory region (in terms of number of descriptors). It is an encoded value that specifies region size as 2^(5+reg_size) number of descriptors. Queue Manager Memory Region R Control Registers The following sections describe each of the four register locations that may be present for each queue in the queues region. For reasons of implementation and area efficiency, these registers are not actually implemented as a huge array of flip flops but are instead implemented as a single set of mailbox registers which use the LSBs of the provided address as a queue index. Due to this implementation all accesses to these registers need to be performed as a single burst write for each packet push operation or a single burst read for each packet pop operation. The length of a burst to push or pop a packet will vary depending on the optional features that the queue supports which may be 4, 8, 12 or 16 bytes. Queue N Register D must always be written / read in the burst but the preceding words are optional depending on the required queue functionality.

Table 16-381. QMEMCTRL2 Register Field Descriptions

Bit	Field	Type	Reset	Description
29-16	START_INDEX	R/W	0h	This field indicates where in linking RAM does the descriptor linking information corresponding to memory region R starts.
11-8	DESC_SIZE	R/W	0h	This field indicates the size of each descriptor in this memory region. It is an encoded value that specifies descriptor size as 2^(5+desc_size) number of bytes. The settings of desc_size from 9-15 are reserved.
2-0	REG_SIZE	R/W	0h	This field indicates the size of the memory region (in terms of number of descriptors). It is an encoded value that specifies region size as 2^(5+reg_size) number of descriptors. Queue Manager Memory Region R Control Registers The following sections describe each of the four register locations that may be present for each queue in the queues region. For reasons of implementation and area efficiency, these registers are not actually implemented as a huge array of flip flops but are instead implemented as a single set of mailbox registers which use the LSBs of the provided address as a queue index. Due to this implementation all accesses to these registers need to be performed as a single burst write for each packet push operation or a single burst read for each packet pop operation. The length of a burst to push or pop a packet will vary depending on the optional features that the queue supports which may be 4, 8, 12 or 16 bytes. Queue N Register D must always be written / read in the burst but the preceding words are optional depending on the required queue functionality.

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 16-395. QUEUE_0_D Register Field Descriptions

Bit	Field	Type	Reset	Description
31-5	DESC_PTR	R/W	0h	Descriptor pointer. It will be read as zero if the queue is empty. It will indicate a 32-bit aligned address that points to a descriptor when the queue is not empty.
4-0	DESC_SIZE	R/W	0h	Descriptor Size. It is encoded in 4-byte increments with values 0 to 31 representing 24 and so on to 148 bytes. This field will return a 0x0 when an empty queue is read. Queue Manager Queue N Registers D To save hardware resources, the queue manager internally stores descriptor size (desc_size) information in four bits. However, register D has five LSBs that specify descriptor size. As a consequence, the value of desc_size that is pushed may not be same as that is read during a pop. The value that is read back is equal to always rounded to an odd number. So, for even values, the value read back is one more than what was written. For odd values, the value read back is same as the value that was written. Note that this 5-bit field (desc_size) is unrelated to the code for size of descriptors in a descriptor region. It is just a place holder for a 5-bit value that is maintained across the push and pop operations for every descriptor managed by the queue manager.

Table 16-399. QUEUE_1_D Register Field Descriptions

Bit	Field	Type	Reset	Description
31-5	DESC_PTR	R/W	0h	Descriptor pointer. It will be read as zero if the queue is empty. It will indicate a 32-bit aligned address that points to a descriptor when the queue is not empty.
4-0	DESC_SIZE	R/W	0h	Descriptor Size. It is encoded in 4-byte increments with values 0 to 31 representing 24 and so on to 148 bytes. This field will return a 0x0 when an empty queue is read. Queue Manager Queue N Registers D To save hardware resources, the queue manager internally stores descriptor size (desc_size) information in four bits. However, register D has five LSBs that specify descriptor size. As a consequence, the value of desc_size that is pushed may not be same as that is read during a pop. The value that is read back is equal to always rounded to an odd number. So, for even values, the value read back is one more than what was written. For odd values, the value read back is same as the value that was written. Note that this 5-bit field (desc_size) is unrelated to the code for size of descriptors in a descriptor region. It is just a place holder for a 5-bit value that is maintained across the push and pop operations for every descriptor managed by the queue manager.

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 16-419. QUEUE_6_D Register Field Descriptions

Bit	Field	Type	Reset	Description
31-5	DESC_PTR	R/W	0h	Descriptor pointer. It will be read as zero if the queue is empty. It will indicate a 32-bit aligned address that points to a descriptor when the queue is not empty.
4-0	DESC_SIZE	R/W	0h	Descriptor Size. It is encoded in 4-byte increments with values 0 to 31 representing 24 and so on to 148 bytes. This field will return a 0x0 when an empty queue is read. Queue Manager Queue N Registers D To save hardware resources, the queue manager internally stores descriptor size (desc_size) information in four bits. However, register D has five LSBs that specify descriptor size. As a consequence, the value of desc_size that is pushed may not be same as that is read during a pop. The value that is read back is equal to always rounded to an odd number. So, for even values, the value read back is one more than what was written. For odd values, the value read back is same as the value that was written. Note that this 5-bit field (desc_size) is unrelated to the code for size of descriptors in a descriptor region. It is just a place holder for a 5-bit value that is maintained across the push and pop operations for every descriptor managed by the queue manager.

Table 16-439. QUEUE_11_D Register Field Descriptions

Bit	Field	Type	Reset	Description
31-5	DESC_PTR	R/W	0h	Descriptor pointer. It will be read as zero if the queue is empty. It will indicate a 32-bit aligned address that points to a descriptor when the queue is not empty.
4-0	DESC_SIZE	R/W	0h	Descriptor Size. It is encoded in 4-byte increments with values 0 to 31 representing 24 and so on to 148 bytes. This field will return a 0x0 when an empty queue is read. Queue Manager Queue N Registers D To save hardware resources, the queue manager internally stores descriptor size (desc_size) information in four bits. However, register D has five LSBs that specify descriptor size. As a consequence, the value of desc_size that is pushed may not be same as that is read during a pop. The value that is read back is equal to always rounded to an odd number. So, for even values, the value read back is one more than what was written. For odd values, the value read back is same as the value that was written. Note that this 5-bit field (desc_size) is unrelated to the code for size of descriptors in a descriptor region. It is just a place holder for a 5-bit value that is maintained across the push and pop operations for every descriptor managed by the queue manager.

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 16-459. QUEUE_16_D Register Field Descriptions

Bit	Field	Type	Reset	Description
31-5	DESC_PTR	R/W	0h	Descriptor pointer. It will be read as zero if the queue is empty. It will indicate a 32-bit aligned address that points to a descriptor when the queue is not empty.
4-0	DESC_SIZE	R/W	0h	Descriptor Size. It is encoded in 4-byte increments with values 0 to 31 representing 24 and so on to 148 bytes. This field will return a 0x0 when an empty queue is read. Queue Manager Queue N Registers D To save hardware resources, the queue manager internally stores descriptor size (desc_size) information in four bits. However, register D has five LSBs that specify descriptor size. As a consequence, the value of desc_size that is pushed may not be same as that is read during a pop. The value that is read back is equal to always rounded to an odd number. So, for even values, the value read back is one more than what was written. For odd values, the value read back is same as the value that was written. Note that this 5-bit field (desc_size) is unrelated to the code for size of descriptors in a descriptor region. It is just a place holder for a 5-bit value that is maintained across the push and pop operations for every descriptor managed by the queue manager.

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 16-475. QUEUE_20_D Register Field Descriptions

Bit	Field	Type	Reset	Description
31-5	DESC_PTR	R/W	0h	Descriptor pointer. It will be read as zero if the queue is empty. It will indicate a 32-bit aligned address that points to a descriptor when the queue is not empty.
4-0	DESC_SIZE	R/W	0h	Descriptor Size. It is encoded in 4-byte increments with values 0 to 31 representing 24 and so on to 148 bytes. This field will return a 0x0 when an empty queue is read. Queue Manager Queue N Registers D To save hardware resources, the queue manager internally stores descriptor size (desc_size) information in four bits. However, register D has five LSBs that specify descriptor size. As a consequence, the value of desc_size that is pushed may not be same as that is read during a pop. The value that is read back is equal to always rounded to an odd number. So, for even values, the value read back is one more than what was written. For odd values, the value read back is same as the value that was written. Note that this 5-bit field (desc_size) is unrelated to the code for size of descriptors in a descriptor region. It is just a place holder for a 5-bit value that is maintained across the push and pop operations for every descriptor managed by the queue manager.

Table 16-495. QUEUE_25_D Register Field Descriptions

Bit	Field	Type	Reset	Description
31-5	DESC_PTR	R/W	0h	Descriptor pointer. It will be read as zero if the queue is empty. It will indicate a 32-bit aligned address that points to a descriptor when the queue is not empty.
4-0	DESC_SIZE	R/W	0h	Descriptor Size. It is encoded in 4-byte increments with values 0 to 31 representing 24 and so on to 148 bytes. This field will return a 0x0 when an empty queue is read. Queue Manager Queue N Registers D To save hardware resources, the queue manager internally stores descriptor size (desc_size) information in four bits. However, register D has five LSBs that specify descriptor size. As a consequence, the value of desc_size that is pushed may not be same as that is read during a pop. The value that is read back is equal to always rounded to an odd number. So, for even values, the value read back is one more than what was written. For odd values, the value read back is same as the value that was written. Note that this 5-bit field (desc_size) is unrelated to the code for size of descriptors in a descriptor region. It is just a place holder for a 5-bit value that is maintained across the push and pop operations for every descriptor managed by the queue manager.

Table 16-515. QUEUE_30_D Register Field Descriptions

Bit	Field	Type	Reset	Description
31-5	DESC_PTR	R/W	0h	Descriptor pointer. It will be read as zero if the queue is empty. It will indicate a 32-bit aligned address that points to a descriptor when the queue is not empty.
4-0	DESC_SIZE	R/W	0h	Descriptor Size. It is encoded in 4-byte increments with values 0 to 31 representing 24 and so on to 148 bytes. This field will return a 0x0 when an empty queue is read. Queue Manager Queue N Registers D To save hardware resources, the queue manager internally stores descriptor size (desc_size) information in four bits. However, register D has five LSBs that specify descriptor size. As a consequence, the value of desc_size that is pushed may not be same as that is read during a pop. The value that is read back is equal to always rounded to an odd number. So, for even values, the value read back is one more than what was written. For odd values, the value read back is same as the value that was written. Note that this 5-bit field (desc_size) is unrelated to the code for size of descriptors in a descriptor region. It is just a place holder for a 5-bit value that is maintained across the push and pop operations for every descriptor managed by the queue manager.

However, register D has five LSBs that specify descriptor size. As a consequence, the value of desc_size that is pushed may not be same as that is read during a pop. The value that is read back is equal to always rounded to an odd number. So, for even values, the value read back is one more than what was written. For odd values, the value read back is same as the value that was written. Note that this 5-bit field (desc_size) is unrelated to the code for size of descriptors in a descriptor region. It is just a place holder for a 5-bit value that is maintained across the push and pop operations for every descriptor managed by the queue manager.

Table 16-551. QUEUE_39_D Register Field Descriptions

Bit	Field	Type	Reset	Description
31-5	DESC_PTR	R/W	0h	Descriptor pointer. It will be read as zero if the queue is empty. It will indicate a 32-bit aligned address that points to a descriptor when the queue is not empty.
4-0	DESC_SIZE	R/W	0h	Descriptor Size. It is encoded in 4-byte increments with values 0 to 31 representing 24 and so on to 148 bytes. This field will return a 0x0 when an empty queue is read. Queue Manager Queue N Registers D To save hardware resources, the queue manager internally stores descriptor size (desc_size) information in four bits. However, register D has five LSBs that specify descriptor size. As a consequence, the value of desc_size that is pushed may not be same as that is read during a pop. The value that is read back is equal to always rounded to an odd number. So, for even values, the value read back is one more than what was written. For odd values, the value read back is same as the value that was written. Note that this 5-bit field (desc_size) is unrelated to the code for size of descriptors in a descriptor region. It is just a place holder for a 5-bit value that is maintained across the push and pop operations for every descriptor managed by the queue manager.

Table 16-571. QUEUE_44_D Register Field Descriptions

Bit	Field	Type	Reset	Description
31-5	DESC_PTR	R/W	0h	Descriptor pointer. It will be read as zero if the queue is empty. It will indicate a 32-bit aligned address that points to a descriptor when the queue is not empty.
4-0	DESC_SIZE	R/W	0h	Descriptor Size. It is encoded in 4-byte increments with values 0 to 31 representing 24 and so on to 148 bytes. This field will return a 0x0 when an empty queue is read. Queue Manager Queue N Registers D To save hardware resources, the queue manager internally stores descriptor size (desc_size) information in four bits. However, register D has five LSBs that specify descriptor size. As a consequence, the value of desc_size that is pushed may not be same as that is read during a pop. The value that is read back is equal to always rounded to an odd number. So, for even values, the value read back is one more than what was written. For odd values, the value read back is same as the value that was written. Note that this 5-bit field (desc_size) is unrelated to the code for size of descriptors in a descriptor region. It is just a place holder for a 5-bit value that is maintained across the push and pop operations for every descriptor managed by the queue manager.

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 16-591. QUEUE_49_D Register Field Descriptions

Bit	Field	Type	Reset	Description
31-5	DESC_PTR	R/W	0h	Descriptor pointer. It will be read as zero if the queue is empty. It will indicate a 32-bit aligned address that points to a descriptor when the queue is not empty.
4-0	DESC_SIZE	R/W	0h	Descriptor Size. It is encoded in 4-byte increments with values 0 to 31 representing 24 and so on to 148 bytes. This field will return a 0x0 when an empty queue is read. Queue Manager Queue N Registers D To save hardware resources, the queue manager internally stores descriptor size (desc_size) information in four bits. However, register D has five LSBs that specify descriptor size. As a consequence, the value of desc_size that is pushed may not be same as that is read during a pop. The value that is read back is equal to always rounded to an odd number. So, for even values, the value read back is one more than what was written. For odd values, the value read back is same as the value that was written. Note that this 5-bit field (desc_size) is unrelated to the code for size of descriptors in a descriptor region. It is just a place holder for a 5-bit value that is maintained across the push and pop operations for every descriptor managed by the queue manager.

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 16-607. QUEUE_53_D Register Field Descriptions

Bit	Field	Type	Reset	Description
31-5	DESC_PTR	R/W	0h	Descriptor pointer. It will be read as zero if the queue is empty. It will indicate a 32-bit aligned address that points to a descriptor when the queue is not empty.
4-0	DESC_SIZE	R/W	0h	Descriptor Size. It is encoded in 4-byte increments with values 0 to 31 representing 24 and so on to 148 bytes. This field will return a 0x0 when an empty queue is read. Queue Manager Queue N Registers D To save hardware resources, the queue manager internally stores descriptor size (desc_size) information in four bits. However, register D has five LSBs that specify descriptor size. As a consequence, the value of desc_size that is pushed may not be same as that is read during a pop. The value that is read back is equal to always rounded to an odd number. So, for even values, the value read back is one more than what was written. For odd values, the value read back is same as the value that was written. Note that this 5-bit field (desc_size) is unrelated to the code for size of descriptors in a descriptor region. It is just a place holder for a 5-bit value that is maintained across the push and pop operations for every descriptor managed by the queue manager.

Table 16-627. QUEUE_58_D Register Field Descriptions

Bit	Field	Type	Reset	Description
31-5	DESC_PTR	R/W	0h	Descriptor pointer. It will be read as zero if the queue is empty. It will indicate a 32-bit aligned address that points to a descriptor when the queue is not empty.
4-0	DESC_SIZE	R/W	0h	Descriptor Size. It is encoded in 4-byte increments with values 0 to 31 representing 24 and so on to 148 bytes. This field will return a 0x0 when an empty queue is read. Queue Manager Queue N Registers D To save hardware resources, the queue manager internally stores descriptor size (desc_size) information in four bits. However, register D has five LSBs that specify descriptor size. As a consequence, the value of desc_size that is pushed may not be same as that is read during a pop. The value that is read back is equal to always rounded to an odd number. So, for even values, the value read back is one more than what was written. For odd values, the value read back is same as the value that was written. Note that this 5-bit field (desc_size) is unrelated to the code for size of descriptors in a descriptor region. It is just a place holder for a 5-bit value that is maintained across the push and pop operations for every descriptor managed by the queue manager.

Table 16-647. QUEUE_63_D Register Field Descriptions

Bit	Field	Type	Reset	Description
31-5	DESC_PTR	R/W	0h	Descriptor pointer. It will be read as zero if the queue is empty. It will indicate a 32-bit aligned address that points to a descriptor when the queue is not empty.
4-0	DESC_SIZE	R/W	0h	Descriptor Size. It is encoded in 4-byte increments with values 0 to 31 representing 24 and so on to 148 bytes. This field will return a 0x0 when an empty queue is read. Queue Manager Queue N Registers D To save hardware resources, the queue manager internally stores descriptor size (desc_size) information in four bits. However, register D has five LSBs that specify descriptor size. As a consequence, the value of desc_size that is pushed may not be same as that is read during a pop. The value that is read back is equal to always rounded to an odd number. So, for even values, the value read back is one more than what was written. For odd values, the value read back is same as the value that was written. Note that this 5-bit field (desc_size) is unrelated to the code for size of descriptors in a descriptor region. It is just a place holder for a 5-bit value that is maintained across the push and pop operations for every descriptor managed by the queue manager.

However, register D has five LSBs that specify descriptor size. As a consequence, the value of desc_size that is pushed may not be same as that is read during a pop. The value that is read back is equal to always rounded to an odd number. So, for even values, the value read back is one more than what was written. For odd values, the value read back is same as the value that was written. Note that this 5-bit field (desc_size) is unrelated to the code for size of descriptors in a descriptor region. It is just a place holder for a 5-bit value that is maintained across the push and pop operations for every descriptor managed by the queue manager.

Table 16-683. QUEUE_72_D Register Field Descriptions

Bit	Field	Type	Reset	Description
31-5	DESC_PTR	R/W	0h	Descriptor pointer. It will be read as zero if the queue is empty. It will indicate a 32-bit aligned address that points to a descriptor when the queue is not empty.
4-0	DESC_SIZE	R/W	0h	Descriptor Size. It is encoded in 4-byte increments with values 0 to 31 representing 24 and so on to 148 bytes. This field will return a 0x0 when an empty queue is read. Queue Manager Queue N Registers D To save hardware resources, the queue manager internally stores descriptor size (desc_size) information in four bits. However, register D has five LSBs that specify descriptor size. As a consequence, the value of desc_size that is pushed may not be same as that is read during a pop. The value that is read back is equal to always rounded to an odd number. So, for even values, the value read back is one more than what was written. For odd values, the value read back is same as the value that was written. Note that this 5-bit field (desc_size) is unrelated to the code for size of descriptors in a descriptor region. It is just a place holder for a 5-bit value that is maintained across the push and pop operations for every descriptor managed by the queue manager.

Table 16-703. QUEUE_77_D Register Field Descriptions

Bit	Field	Type	Reset	Description
31-5	DESC_PTR	R/W	0h	Descriptor pointer. It will be read as zero if the queue is empty. It will indicate a 32-bit aligned address that points to a descriptor when the queue is not empty.
4-0	DESC_SIZE	R/W	0h	Descriptor Size. It is encoded in 4-byte increments with values 0 to 31 representing 24 and so on to 148 bytes. This field will return a 0x0 when an empty queue is read. Queue Manager Queue N Registers D To save hardware resources, the queue manager internally stores descriptor size (desc_size) information in four bits. However, register D has five LSBs that specify descriptor size. As a consequence, the value of desc_size that is pushed may not be same as that is read during a pop. The value that is read back is equal to always rounded to an odd number. So, for even values, the value read back is one more than what was written. For odd values, the value read back is same as the value that was written. Note that this 5-bit field (desc_size) is unrelated to the code for size of descriptors in a descriptor region. It is just a place holder for a 5-bit value that is maintained across the push and pop operations for every descriptor managed by the queue manager.

Table 16-723. QUEUE_82_D Register Field Descriptions

Bit	Field	Type	Reset	Description
31-5	DESC_PTR	R/W	0h	Descriptor pointer. It will be read as zero if the queue is empty. It will indicate a 32-bit aligned address that points to a descriptor when the queue is not empty.
4-0	DESC_SIZE	R/W	0h	Descriptor Size. It is encoded in 4-byte increments with values 0 to 31 representing 24 and so on to 148 bytes. This field will return a 0x0 when an empty queue is read. Queue Manager Queue N Registers D To save hardware resources, the queue manager internally stores descriptor size (desc_size) information in four bits. However, register D has five LSBs that specify descriptor size. As a consequence, the value of desc_size that is pushed may not be same as that is read during a pop. The value that is read back is equal to always rounded to an odd number. So, for even values, the value read back is one more than what was written. For odd values, the value read back is same as the value that was written. Note that this 5-bit field (desc_size) is unrelated to the code for size of descriptors in a descriptor region. It is just a place holder for a 5-bit value that is maintained across the push and pop operations for every descriptor managed by the queue manager.

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 16-739. QUEUE_86_D Register Field Descriptions

Bit	Field	Type	Reset	Description
31-5	DESC_PTR	R/W	0h	Descriptor pointer. It will be read as zero if the queue is empty. It will indicate a 32-bit aligned address that points to a descriptor when the queue is not empty.
4-0	DESC_SIZE	R/W	0h	Descriptor Size. It is encoded in 4-byte increments with values 0 to 31 representing 24 and so on to 148 bytes. This field will return a 0x0 when an empty queue is read. Queue Manager Queue N Registers D To save hardware resources, the queue manager internally stores descriptor size (desc_size) information in four bits. However, register D has five LSBs that specify descriptor size. As a consequence, the value of desc_size that is pushed may not be same as that is read during a pop. The value that is read back is equal to always rounded to an odd number. So, for even values, the value read back is one more than what was written. For odd values, the value read back is same as the value that was written. Note that this 5-bit field (desc_size) is unrelated to the code for size of descriptors in a descriptor region. It is just a place holder for a 5-bit value that is maintained across the push and pop operations for every descriptor managed by the queue manager.

Table 16-759. QUEUE_91_D Register Field Descriptions

Bit	Field	Type	Reset	Description
31-5	DESC_PTR	R/W	0h	Descriptor pointer. It will be read as zero if the queue is empty. It will indicate a 32-bit aligned address that points to a descriptor when the queue is not empty.
4-0	DESC_SIZE	R/W	0h	Descriptor Size. It is encoded in 4-byte increments with values 0 to 31 representing 24 and so on to 148 bytes. This field will return a 0x0 when an empty queue is read. Queue Manager Queue N Registers D To save hardware resources, the queue manager internally stores descriptor size (desc_size) information in four bits. However, register D has five LSBs that specify descriptor size. As a consequence, the value of desc_size that is pushed may not be same as that is read during a pop. The value that is read back is equal to always rounded to an odd number. So, for even values, the value read back is one more than what was written. For odd values, the value read back is same as the value that was written. Note that this 5-bit field (desc_size) is unrelated to the code for size of descriptors in a descriptor region. It is just a place holder for a 5-bit value that is maintained across the push and pop operations for every descriptor managed by the queue manager.

Table 16-779. QUEUE_96_D Register Field Descriptions

Bit	Field	Type	Reset	Description
31-5	DESC_PTR	R/W	0h	Descriptor pointer. It will be read as zero if the queue is empty. It will indicate a 32-bit aligned address that points to a descriptor when the queue is not empty.
4-0	DESC_SIZE	R/W	0h	Descriptor Size. It is encoded in 4-byte increments with values 0 to 31 representing 24 and so on to 148 bytes. This field will return a 0x0 when an empty queue is read. Queue Manager Queue N Registers D To save hardware resources, the queue manager internally stores descriptor size (desc_size) information in four bits. However, register D has five LSBs that specify descriptor size. As a consequence, the value of desc_size that is pushed may not be same as that is read during a pop. The value that is read back is equal to always rounded to an odd number. So, for even values, the value read back is one more than what was written. For odd values, the value read back is same as the value that was written. Note that this 5-bit field (desc_size) is unrelated to the code for size of descriptors in a descriptor region. It is just a place holder for a 5-bit value that is maintained across the push and pop operations for every descriptor managed by the queue manager.

Table 16-799. QUEUE_101_D Register Field Descriptions

Bit	Field	Type	Reset	Description
31-5	DESC_PTR	R/W	0h	Descriptor pointer. It will be read as zero if the queue is empty. It will indicate a 32-bit aligned address that points to a descriptor when the queue is not empty.
4-0	DESC_SIZE	R/W	0h	Descriptor Size. It is encoded in 4-byte increments with values 0 to 31 representing 24 and so on to 148 bytes. This field will return a 0x0 when an empty queue is read. Queue Manager Queue N Registers D To save hardware resources, the queue manager internally stores descriptor size (desc_size) information in four bits. However, register D has five LSBs that specify descriptor size. As a consequence, the value of desc_size that is pushed may not be same as that is read during a pop. The value that is read back is equal to always rounded to an odd number. So, for even values, the value read back is one more than what was written. For odd values, the value read back is same as the value that was written. Note that this 5-bit field (desc_size) is unrelated to the code for size of descriptors in a descriptor region. It is just a place holder for a 5-bit value that is maintained across the push and pop operations for every descriptor managed by the queue manager.

Table 16-819. QUEUE_106_D Register Field Descriptions

Bit	Field	Type	Reset	Description
31-5	DESC_PTR	R/W	0h	Descriptor pointer. It will be read as zero if the queue is empty. It will indicate a 32-bit aligned address that points to a descriptor when the queue is not empty.
4-0	DESC_SIZE	R/W	0h	Descriptor Size. It is encoded in 4-byte increments with values 0 to 31 representing 24 and so on to 148 bytes. This field will return a 0x0 when an empty queue is read. Queue Manager Queue N Registers D To save hardware resources, the queue manager internally stores descriptor size (desc_size) information in four bits. However, register D has five LSBs that specify descriptor size. As a consequence, the value of desc_size that is pushed may not be same as that is read during a pop. The value that is read back is equal to always rounded to an odd number. So, for even values, the value read back is one more than what was written. For odd values, the value read back is same as the value that was written. Note that this 5-bit field (desc_size) is unrelated to the code for size of descriptors in a descriptor region. It is just a place holder for a 5-bit value that is maintained across the push and pop operations for every descriptor managed by the queue manager.

Table 16-835. QUEUE_110_D Register Field Descriptions

Bit	Field	Type	Reset	Description
31-5	DESC_PTR	R/W	0h	Descriptor pointer. It will be read as zero if the queue is empty. It will indicate a 32-bit aligned address that points to a descriptor when the queue is not empty.
4-0	DESC_SIZE	R/W	0h	Descriptor Size. It is encoded in 4-byte increments with values 0 to 31 representing 24 and so on to 148 bytes. This field will return a 0x0 when an empty queue is read. Queue Manager Queue N Registers D To save hardware resources, the queue manager internally stores descriptor size (desc_size) information in four bits. However, register D has five LSBs that specify descriptor size. As a consequence, the value of desc_size that is pushed may not be same as that is read during a pop. The value that is read back is equal to always rounded to an odd number. So, for even values, the value read back is one more than what was written. For odd values, the value read back is same as the value that was written. Note that this 5-bit field (desc_size) is unrelated to the code for size of descriptors in a descriptor region. It is just a place holder for a 5-bit value that is maintained across the push and pop operations for every descriptor managed by the queue manager.

Table 16-855. QUEUE_115_D Register Field Descriptions

Bit	Field	Type	Reset	Description
31-5	DESC_PTR	R/W	0h	Descriptor pointer. It will be read as zero if the queue is empty. It will indicate a 32-bit aligned address that points to a descriptor when the queue is not empty.
4-0	DESC_SIZE	R/W	0h	Descriptor Size. It is encoded in 4-byte increments with values 0 to 31 representing 24 and so on to 148 bytes. This field will return a 0x0 when an empty queue is read. Queue Manager Queue N Registers D To save hardware resources, the queue manager internally stores descriptor size (desc_size) information in four bits. However, register D has five LSBs that specify descriptor size. As a consequence, the value of desc_size that is pushed may not be same as that is read during a pop. The value that is read back is equal to always rounded to an odd number. So, for even values, the value read back is one more than what was written. For odd values, the value read back is same as the value that was written. Note that this 5-bit field (desc_size) is unrelated to the code for size of descriptors in a descriptor region. It is just a place holder for a 5-bit value that is maintained across the push and pop operations for every descriptor managed by the queue manager.

Queue Manager Queue N Registers D To save hardware resources, the queue manager internally stores descriptor size (desc_size) information in four bits. However, register D has five LSBs that specify descriptor size. As a consequence, the value of desc_size that is pushed may not be same as that is read during a pop. The value that is read back is equal to always rounded to an odd number. So, for even values, the value read back is one more than what was written. For odd values, the value read back is same as the value that was written. Note that this 5-bit field (desc_size) is unrelated to the code for size of descriptors in a descriptor region. It is just a place holder for a 5-bit value that is maintained across the push and pop operations for every descriptor managed by the queue manager.

Table 16-895. QUEUE_125_D Register Field Descriptions

Bit	Field	Type	Reset	Description
31-5	DESC_PTR	R/W	0h	Descriptor pointer. It will be read as zero if the queue is empty. It will indicate a 32-bit aligned address that points to a descriptor when the queue is not empty.
4-0	DESC_SIZE	R/W	0h	Descriptor Size. It is encoded in 4-byte increments with values 0 to 31 representing 24 and so on to 148 bytes. This field will return a 0x0 when an empty queue is read. Queue Manager Queue N Registers D To save hardware resources, the queue manager internally stores descriptor size (desc_size) information in four bits. However, register D has five LSBs that specify descriptor size. As a consequence, the value of desc_size that is pushed may not be same as that is read during a pop. The value that is read back is equal to always rounded to an odd number. So, for even values, the value read back is one more than what was written. For odd values, the value read back is same as the value that was written. Note that this 5-bit field (desc_size) is unrelated to the code for size of descriptors in a descriptor region. It is just a place holder for a 5-bit value that is maintained across the push and pop operations for every descriptor managed by the queue manager.

Table 16-915. QUEUE_130_D Register Field Descriptions

Bit	Field	Type	Reset	Description
31-5	DESC_PTR	R/W	0h	Descriptor pointer. It will be read as zero if the queue is empty. It will indicate a 32-bit aligned address that points to a descriptor when the queue is not empty.
4-0	DESC_SIZE	R/W	0h	Descriptor Size. It is encoded in 4-byte increments with values 0 to 31 representing 24 and so on to 148 bytes. This field will return a 0x0 when an empty queue is read. Queue Manager Queue N Registers D To save hardware resources, the queue manager internally stores descriptor size (desc_size) information in four bits. However, register D has five LSBs that specify descriptor size. As a consequence, the value of desc_size that is pushed may not be same as that is read during a pop. The value that is read back is equal to always rounded to an odd number. So, for even values, the value read back is one more than what was written. For odd values, the value read back is same as the value that was written. Note that this 5-bit field (desc_size) is unrelated to the code for size of descriptors in a descriptor region. It is just a place holder for a 5-bit value that is maintained across the push and pop operations for every descriptor managed by the queue manager.

Table 16-935. QUEUE_135_D Register Field Descriptions

Bit	Field	Type	Reset	Description
31-5	DESC_PTR	R/W	0h	Descriptor pointer. It will be read as zero if the queue is empty. It will indicate a 32-bit aligned address that points to a descriptor when the queue is not empty.
4-0	DESC_SIZE	R/W	0h	Descriptor Size. It is encoded in 4-byte increments with values 0 to 31 representing 24 and so on to 148 bytes. This field will return a 0x0 when an empty queue is read. Queue Manager Queue N Registers D To save hardware resources, the queue manager internally stores descriptor size (desc_size) information in four bits. However, register D has five LSBs that specify descriptor size. As a consequence, the value of desc_size that is pushed may not be same as that is read during a pop. The value that is read back is equal to always rounded to an odd number. So, for even values, the value read back is one more than what was written. For odd values, the value read back is same as the value that was written. Note that this 5-bit field (desc_size) is unrelated to the code for size of descriptors in a descriptor region. It is just a place holder for a 5-bit value that is maintained across the push and pop operations for every descriptor managed by the queue manager.

Table 16-955. QUEUE_140_D Register Field Descriptions

Bit	Field	Type	Reset	Description
31-5	DESC_PTR	R/W	0h	Descriptor pointer. It will be read as zero if the queue is empty. It will indicate a 32-bit aligned address that points to a descriptor when the queue is not empty.
4-0	DESC_SIZE	R/W	0h	Descriptor Size. It is encoded in 4-byte increments with values 0 to 31 representing 24 and so on to 148 bytes. This field will return a 0x0 when an empty queue is read. Queue Manager Queue N Registers D To save hardware resources, the queue manager internally stores descriptor size (desc_size) information in four bits. However, register D has five LSBs that specify descriptor size. As a consequence, the value of desc_size that is pushed may not be same as that is read during a pop. The value that is read back is equal to always rounded to an odd number. So, for even values, the value read back is one more than what was written. For odd values, the value read back is same as the value that was written. Note that this 5-bit field (desc_size) is unrelated to the code for size of descriptors in a descriptor region. It is just a place holder for a 5-bit value that is maintained across the push and pop operations for every descriptor managed by the queue manager.

Table 16-975. QUEUE_145_D Register Field Descriptions

Bit	Field	Type	Reset	Description
31-5	DESC_PTR	R/W	0h	Descriptor pointer. It will be read as zero if the queue is empty. It will indicate a 32-bit aligned address that points to a descriptor when the queue is not empty.
4-0	DESC_SIZE	R/W	0h	Descriptor Size. It is encoded in 4-byte increments with values 0 to 31 representing 24 and so on to 148 bytes. This field will return a 0x0 when an empty queue is read. Queue Manager Queue N Registers D To save hardware resources, the queue manager internally stores descriptor size (desc_size) information in four bits. However, register D has five LSBs that specify descriptor size. As a consequence, the value of desc_size that is pushed may not be same as that is read during a pop. The value that is read back is equal to always rounded to an odd number. So, for even values, the value read back is one more than what was written. For odd values, the value read back is same as the value that was written. Note that this 5-bit field (desc_size) is unrelated to the code for size of descriptors in a descriptor region. It is just a place holder for a 5-bit value that is maintained across the push and pop operations for every descriptor managed by the queue manager.

Table 16-995. QUEUE_150_D Register Field Descriptions

Bit	Field	Type	Reset	Description
31-5	DESC_PTR	R/W	0h	Descriptor pointer. It will be read as zero if the queue is empty. It will indicate a 32-bit aligned address that points to a descriptor when the queue is not empty.
4-0	DESC_SIZE	R/W	0h	Descriptor Size. It is encoded in 4-byte increments with values 0 to 31 representing 24 and so on to 148 bytes. This field will return a 0x0 when an empty queue is read. Queue Manager Queue N Registers D To save hardware resources, the queue manager internally stores descriptor size (desc_size) information in four bits. However, register D has five LSBs that specify descriptor size. As a consequence, the value of desc_size that is pushed may not be same as that is read during a pop. The value that is read back is equal to always rounded to an odd number. So, for even values, the value read back is one more than what was written. For odd values, the value read back is same as the value that was written. Note that this 5-bit field (desc_size) is unrelated to the code for size of descriptors in a descriptor region. It is just a place holder for a 5-bit value that is maintained across the push and pop operations for every descriptor managed by the queue manager.

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; *-n* = value after reset

Table 16-1015. QUEUE_155_D Register Field Descriptions

Bit	Field	Type	Reset	Description
31-5	DESC_PTR	R/W	0h	Descriptor pointer. It will be read as zero if the queue is empty. It will indicate a 32-bit aligned address that points to a descriptor when the queue is not empty.
4-0	DESC_SIZE	R/W	0h	Descriptor Size. It is encoded in 4-byte increments with values 0 to 31 representing 24 and so on to 148 bytes. This field will return a 0x0 when an empty queue is read. Queue Manager Queue N Registers D To save hardware resources, the queue manager internally stores descriptor size (desc_size) information in four bits. However, register D has five LSBs that specify descriptor size. As a consequence, the value of desc_size that is pushed may not be same as that is read during a pop. The value that is read back is equal to always rounded to an odd number. So, for even values, the value read back is one more than what was written. For odd values, the value read back is same as the value that was written. Note that this 5-bit field (desc_size) is unrelated to the code for size of descriptors in a descriptor region. It is just a place holder for a 5-bit value that is maintained across the push and pop operations for every descriptor managed by the queue manager.

17.1 Mailbox

17.1.1 Introduction

17.1.1.1 Features

Global features of the Mailbox module are:

- OCP slave interface (L4) supports:
  - 32-bit data bus width
  - 8/16/32 bit access supported
  - 9-bit address bus width
  - Burst not supported
- 8 mailbox sub-modules
- Each mailbox sub module allows 1-way communication between 2 initiators
- Flexible mailbox/initiators assignment scheme
- 4 messages per mailbox sub-module
- 32-bit message width
- Support of 16/32-bit addressing scheme
- Non-intrusive emulation
- 4 interrupts (one per user: 1 to MPU Subsystem, 2 to PRUSS, and 1 to WakeM3)

17.1.1.2 Unsupported Features

There are no unsupported features for Mailbox on this device.

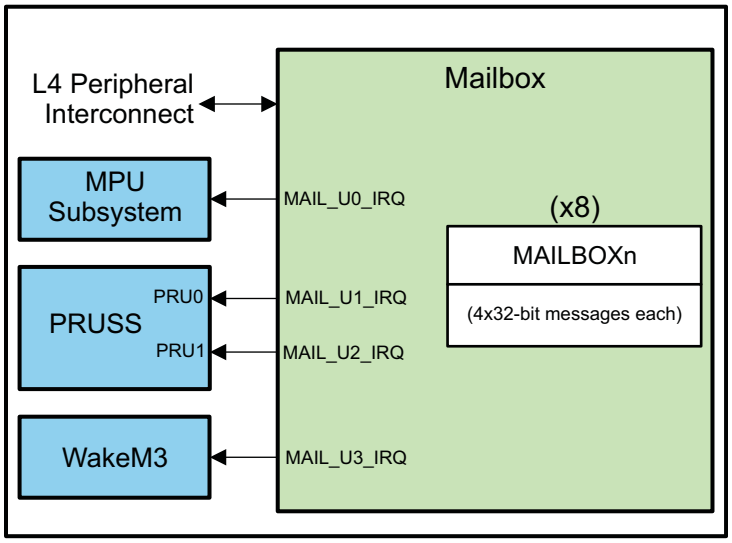
Copyright © 2011, Texas Instruments Incorporated

17.1.2 Integration

This device contains a single instantiation of the Mailbox module at the system level. The mailbox function is made of eight sub-module mailboxes each supporting a 1-way communication between two initiators. The communication protocol from the sender to the receiver is implemented with mailbox registers using interrupts. The sender sends information to the receiver by writing to the mailbox. Interrupt signaling is used to notify the receiver a message has been queued or the sender for overflow situation.

The eight mailboxes are enough to handle communications between the MPU Subsystem, PRUSS PRUs, and WakeM3. Note that because the WakeM3 has access only to L4_Wakeup peripherals it does not have access to the Mailbox registers. A mailbox interrupt can still be sent to the M3 to trigger message notification. The actual message payload must be placed in either M3 internal memory or in the Control Module Interprocessor Message registers (IPC_MSG_REG{0-7}).

Figure 17-1. Mailbox Integration



17.1.2.1 Mailbox Connectivity Attributes

The general connectivity for the Mailbox is shown in Table 17-1.

Table 17-1. Mailbox Connectivity Attributes

Attributes	Type
Power Domain	Peripheral Domain
Clock Domain	L4PER_L4LS_GCLK
Reset Signals	PER_DOM_RST_N
Idle/Wakeup Signals	Smart Idle
Interrupt Requests	4 Interrupts mail_u0 (MBINT0) – to MPU Subsystem mail_u1 – to PRUSS (PRU0) mail_u2 – to PRUSS (PRU1) mail_u3 – to WakeM3
DMA Requests	None
Physical Address	L4 Peripheral slave port

17.1.2.2 Mailbox Clock and Reset Management

The mailbox function operates from the L4 interface clock.

Table 17-2. Mailbox Clock Signals

Clock Signal	Max Freq	Reference / Source	Comments
Functional / Interface clock	100 MHz	CORE_CLKOUTM4 / 2	pd_per_l4ls_gclk From PRCM

17.1.2.3 Mailbox Pin List

The Mailbox module does not include any external interface pins.

17.1.3 MAILBOX Registers

Table 17-3 lists the memory-mapped registers for the MAILBOX. All register offset addresses not listed in Table 17-3 should be considered as reserved locations and the register contents should not be modified.

Table 17-3. MAILBOX REGISTERS

Offset	Acronym	Register Description	Section
0h	REVISION	This register contains the IP revision code	Section 17.1.3.1
10h	SYSCONFIG	This register controls the various parameters of the OCP interface	Section 17.2.1.2

17.1.3.29 IRQENABLE_SET_0 Register (offset = 108h) [reset = 0h]

The interrupt enable register enables to unmask the module internal source of interrupt to the corresponding user. This register is write 1 to set.

IRQENABLE_SET_0 is shown in Figure 17-30 and described in Table 17-32.

17.1.3.31 IRQSTATUS_RAW_1 Register (offset = 110h) [reset = 0h]

The interrupt status register has the status for each event that may be responsible for the generation of an interrupt to the corresponding user - write 1 to a given bit resets this bit. This register is mainly used for debug purpose.

IRQSTATUS_RAW_1 is shown in Figure 17-32 and described in Table 17-34.

17.1.3.33 IRQENABLE_SET_1 Register (offset = 118h) [reset = 0h]

The interrupt enable register enables to unmask the module internal source of interrupt to the corresponding user. This register is write 1 to set.

IRQENABLE_SET_1 is shown in Figure 17-34 and described in Table 17-36.

17.1.3.35 IRQSTATUS_RAW_2 Register (offset = 120h) [reset = 0h]

The interrupt status register has the status for each event that may be responsible for the generation of an interrupt to the corresponding user - write 1 to a given bit resets this bit. This register is mainly used for debug purpose.

IRQSTATUS_RAW_2 is shown in Figure 17-36 and described in Table 17-38.

17.1.3.38 IRQENABLE_CLR_2 Register (offset = 12Ch) [reset = 0h]

The interrupt enable register enables to mask the module internal source of interrupt to the corresponding user. This register is write 1 to clear.

IRQENABLE_CLR_2 is shown in Figure 17-39 and described in Table 17-41.

17.1.3.39 IRQSTATUS_RAW_3 Register (offset = 130h) [reset = 0h]

The interrupt status register has the status for each event that may be responsible for the generation of an interrupt to the corresponding user - write 1 to a given bit resets this bit. This register is mainly used for debug purpose.

IRQSTATUS_RAW_3 is shown in Figure 17-40 and described in Table 17-42.

17.1.3.40 IRQSTATUS_CLR_3 Register (offset = 134h) [reset = 0h]

The interrupt status register has the status combined with irq-enable for each event that may be responsible for the generation of an interrupt to the corresponding user - write 1 to a given bit resets this bit.

IRQSTATUS_CLR_3 is shown in Figure 17-41 and described in Table 17-43.

17.2 Spinlock

17.2.1 SPINLOCK Registers

Table 17-46 lists the memory-mapped registers for the SPINLOCK. All register offset addresses not listed in Table 17-46 should be considered as reserved locations and the register contents should not be modified.

Table 17-46. SPINLOCK REGISTERS

Offset	Acronym	Register Description	Section
0h	REV	Read-only IP revision identifier (X.Y.R) used by software to determine features, bugs and compatibility of an instance of this the Spin Lock module.	Section 17.2.1.1
10h	SYSCONFIG	This register controls the various parameters of the OCP interface. Note that several fields are present by read-only.	Section 17.2.1.2
14h	SYSTATUS	This register provides status information about this instance of the Spin Lock module.	Section 17.2.1.3
800h	LOCK_REG_0	This register is read when attempting to acquire a lock. The lock is automatically taken if it was not taken and the value returned by the read is zero. If the lock was already taken, then the read returns one. Writing a zero to this register frees the lock.	Section 17.2.1.4
804h	LOCK_REG_1	This register is read when attempting to acquire a lock. The lock is automatically taken if it was not taken and the value returned by the read is zero. If the lock was already taken, then the read returns one. Writing a zero to this register frees the lock.	Section 17.2.1.5
808h	LOCK_REG_2	This register is read when attempting to acquire a lock. The lock is automatically taken if it was not taken and the value returned by the read is zero. If the lock was already taken, then the read returns one. Writing a zero to this register frees the lock.	Section 17.2.1.6
80Ch	LOCK_REG_3	This register is read when attempting to acquire a lock. The lock is automatically taken if it was not taken and the value returned by the read is zero. If the lock was already taken, then the read returns one. Writing a zero to this register frees the lock.	Section 17.2.1.7
810h	LOCK_REG_4	This register is read when attempting to acquire a lock. The lock is automatically taken if it was not taken and the value returned by the read is zero. If the lock was already taken, then the read returns one. Writing a zero to this register frees the lock.	Section 17.2.1.8
814h	LOCK_REG_5	This register is read when attempting to acquire a lock. The lock is automatically taken if it was not taken and the value returned by the read is zero. If the lock was already taken, then the read returns one. Writing a zero to this register frees the lock.	Section 17.2.1.9
818h	LOCK_REG_6	This register is read when attempting to acquire a lock. The lock is automatically taken if it was not taken and the value returned by the read is zero. If the lock was already taken, then the read returns one. Writing a zero to this register frees the lock.	Section 17.2.1.10
81Ch	LOCK_REG_7	This register is read when attempting to acquire a lock. The lock is automatically taken if it was not taken and the value returned by the read is zero. If the lock was already taken, then the read returns one. Writing a zero to this register frees the lock.	Section 17.2.1.11
820h	LOCK_REG_8	This register is read when attempting to acquire a lock. The lock is automatically taken if it was not taken and the value returned by the read is zero. If the lock was already taken, then the read returns one. Writing a zero to this register frees the lock.	Section 17.2.1.12

Table 17-46. SPINLOCK REGISTERS (continued)

Offset	Acronym	Register Description	Section
824h	LOCK_REG_9	This register is read when attempting to acquire a lock. The lock is automatically taken if it was not taken and the value returned by the read is zero. If the lock was already taken, then the read returns one. Writing a zero to this register frees the lock.	Section 17.2.1.13
828h	LOCK_REG_10	This register is read when attempting to acquire a lock. The lock is automatically taken if it was not taken and the value returned by the read is zero. If the lock was already taken, then the read returns one. Writing a zero to this register frees the lock.	Section 17.2.1.14
82Ch	LOCK_REG_11	This register is read when attempting to acquire a lock. The lock is automatically taken if it was not taken and the value returned by the read is zero. If the lock was already taken, then the read returns one. Writing a zero to this register frees the lock.	Section 17.2.1.15
830h	LOCK_REG_12	This register is read when attempting to acquire a lock. The lock is automatically taken if it was not taken and the value returned by the read is zero. If the lock was already taken, then the read returns one. Writing a zero to this register frees the lock.	Section 17.2.1.16
834h	LOCK_REG_13	This register is read when attempting to acquire a lock. The lock is automatically taken if it was not taken and the value returned by the read is zero. If the lock was already taken, then the read returns one. Writing a zero to this register frees the lock.	Section 17.2.1.17
838h	LOCK_REG_14	This register is read when attempting to acquire a lock. The lock is automatically taken if it was not taken and the value returned by the read is zero. If the lock was already taken, then the read returns one. Writing a zero to this register frees the lock.	Section 17.2.1.18
83Ch	LOCK_REG_15	This register is read when attempting to acquire a lock. The lock is automatically taken if it was not taken and the value returned by the read is zero. If the lock was already taken, then the read returns one. Writing a zero to this register frees the lock.	Section 17.2.1.19
840h	LOCK_REG_16	This register is read when attempting to acquire a lock. The lock is automatically taken if it was not taken and the value returned by the read is zero. If the lock was already taken, then the read returns one. Writing a zero to this register frees the lock.	Section 17.2.1.20
844h	LOCK_REG_17	This register is read when attempting to acquire a lock. The lock is automatically taken if it was not taken and the value returned by the read is zero. If the lock was already taken, then the read returns one. Writing a zero to this register frees the lock.	Section 17.2.1.21
848h	LOCK_REG_18	This register is read when attempting to acquire a lock. The lock is automatically taken if it was not taken and the value returned by the read is zero. If the lock was already taken, then the read returns one. Writing a zero to this register frees the lock.	Section 17.2.1.22
84Ch	LOCK_REG_19	This register is read when attempting to acquire a lock. The lock is automatically taken if it was not taken and the value returned by the read is zero. If the lock was already taken, then the read returns one. Writing a zero to this register frees the lock.	Section 17.2.1.23
850h	LOCK_REG_20	This register is read when attempting to acquire a lock. The lock is automatically taken if it was not taken and the value returned by the read is zero. If the lock was already taken, then the read returns one. Writing a zero to this register frees the lock.	Section 17.2.1.24

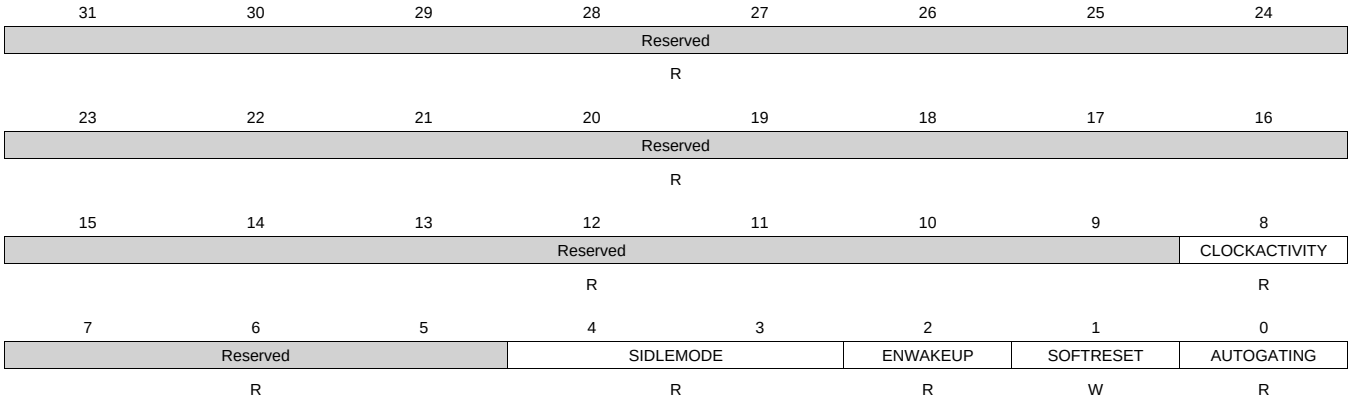
17.2.1.2 SYSCONFIG Register (offset = 10h) [reset = 0h]

This register controls the various parameters of the OCP interface. Note that several fields are present by read-only.

SYSCONFIG is shown in Figure 17-45 and described in Table 17-48.

Figure 17-45. SYSCONFIG Register



LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -*n* = value after reset

Table 17-48. SYSCONFIG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-9	Reserved	R		
8	CLOCKACTIVITY	R		Indicates whether the module requires the OCP when in IDLE mode. 0 - NOTREQUIRED: OCP clock is not required by the module during IDLE mode and may be switched off. 1 - REQUIRED: OCP clock is required by the module, even during idle mode.
7-5	Reserved	R		
4-3	SIDLEMODE	R		Control of the slave interface power management IDLE request acknowledgement. 0 - FORCEIDLE: IDLE request is acknowledged unconditionally and immediately. 1 - NOIDLE: IDLE request is never acknowledged. 2 - SMARTIDLE: IDLE request acknowledgement is based on the internal module activity. 3 - unused3: Reserved. Do not use.
2	ENWAKEUP	R		Asynchronous wakeup gereration. 0 - NOWAKEUPGEN: Wakeup generation is disabled. 1 - WAKEUPGEN1: Enable wakeup generation.
1	SOFTRESET	W		Module software reset. 0 - NOOP: No Description 1 - DORESET: Start a soft reset sequence of the Spin Lock module.
0	AUTOGATING	R		Internal OCP clock gating strategy. 0 - FREERUNNING: OCP clock is not gated when OCP interface is idle. 1 - GATED: Automatic internal OCP clock gating strategy is applied, based on the OCP interface activity.

17.2.1.12 LOCK_REG_8 Register (offset = 820h) [reset = 0h]

This register is read when attempting to acquire a lock. The lock is automatically taken if it was not taken and the value returned by the read is zero. If the lock was already taken, then the read returns one. Writing a zero to this register frees the lock.

LOCK_REG_8 is shown in Figure 17-55 and described in Table 17-58.

17.2.1.32 LOCK_REG_28 Register (offset = 870h) [reset = 0h]

This register is read when attempting to acquire a lock. The lock is automatically taken if it was not taken and the value returned by the read is zero. If the lock was already taken, then the read returns one. Writing a zero to this register frees the lock.

LOCK_REG_28 is shown in Figure 17-75 and described in Table 17-78.

Multimedia Card (MMC)

This chapter describes the MMC of the device.

Topic **Page**

18.1 Introduction 3874
18.2 Integration 3875
18.3 Functional Description 3879
18.4 MMC/SD/SDIO Registers 3917

Copyright © 2011, Texas Instruments Incorporated

18.1 Introduction

18.1.1 MMCHS Features

The general features of the MMCHS host controller IP are:

- Built-in 1024-byte buffer for read or write
- Two DMA channels, one interrupt line
- Clock support
  - 96-MHz functional clock source input
  - up to 384Mbit/sec (48MByte/sec) in MMC mode 8-bit data transfer
  - up to 192Mbit/sec (24MByte/sec) in High-Speed SD mode 4-bit data transfer
  - up to 24Mbit/sec (3MByte/sec) in Default SD mode 1-bit data transfer
- Support for SDA 3.0 Part A2 programming model
- Serial link supports full compliance with:
  - MMC command/response sets as defined in the MMC standard specification v4.3.
  - SD command/response sets as defined in the SD Physical Layer specification v3.00
  - SDIO command/response sets and interrupt/read-wait suspend-resume operations as defined in the SD part E1 specification v 2 .00
  - SD Host Controller Standard Specification sets as defined in the SD card specification Part A2 v2.00

18.1.2 Unsupported MMCHS Features

The MMCHS module features not supported in this device are shown in Table 18-1.

Table 18-1. Unsupported MMCHS Features

Feature	Reason
MMC Out-of-band interrupts	MMC_OBI input tied low
Master DMA operation	Disabled through synthesis parameter
Card Supply Control (MMCHS(1-2))	Signal not pinned out

Copyright © 2011, Texas Instruments Incorporated

18.2 Integration

This device contains three instances of the Multimedia Card (MMC), Secure Digital (SD), and Secure Digital I/O (SDIO) high speed interface module (MMCHS). The controller provides an interface to an MMC, SD memory card or SDIO card.

The application interface is responsible for managing transaction semantics; the MMC/SDIO host controller deals with MMC/SDIO protocol at transmission level, packing data, adding CRC, start/end bit and checking for syntactical correctness. Figure 18-1 through Figure 18-3 below show examples of systems using the MMCHS controller. Note that the power switch control is only available on the MMCHS0 interface.

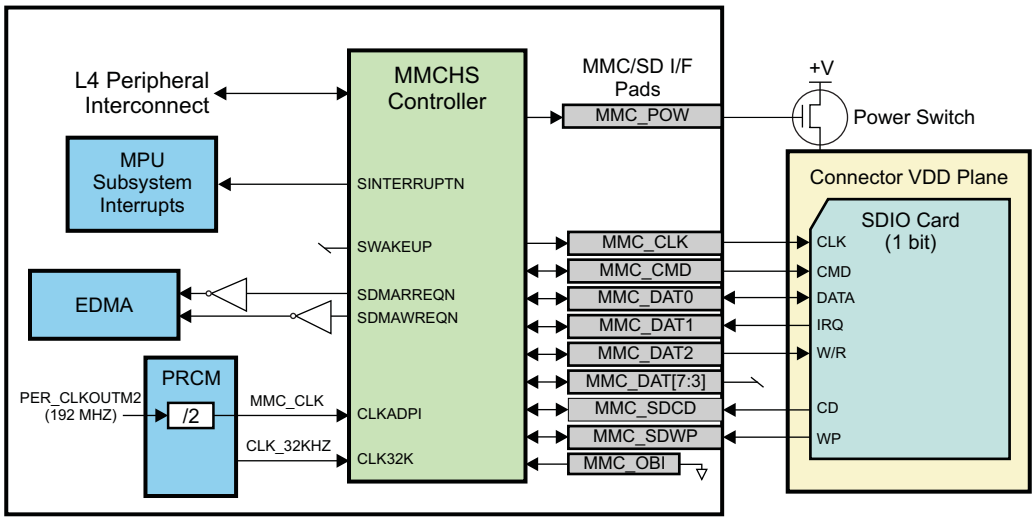

Figure 18-1. MMCHS Module SDIO Application

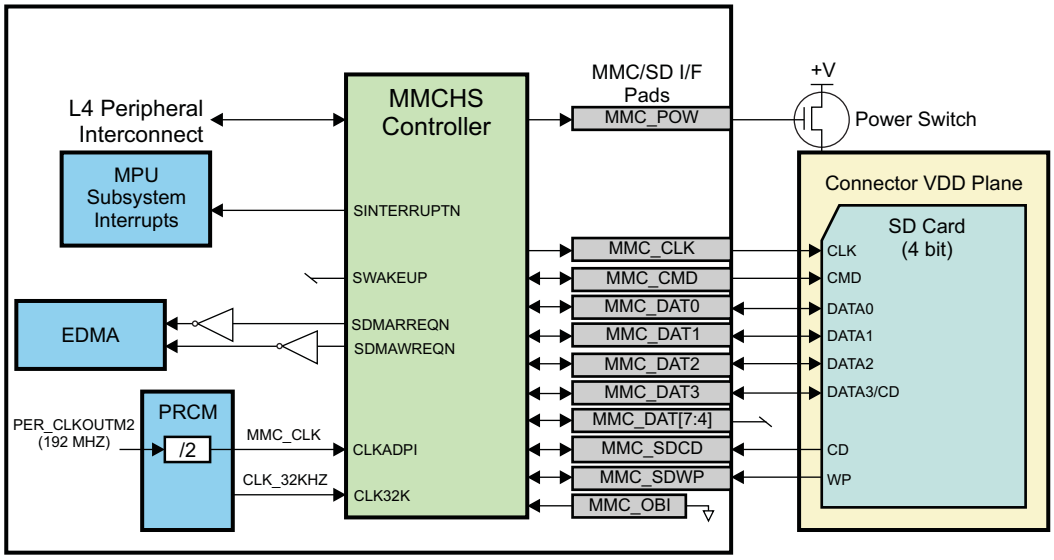

Figure 18-2. MMCHS SD (4-bit) Card Application

Copyright © 2011, Texas Instruments Incorporated

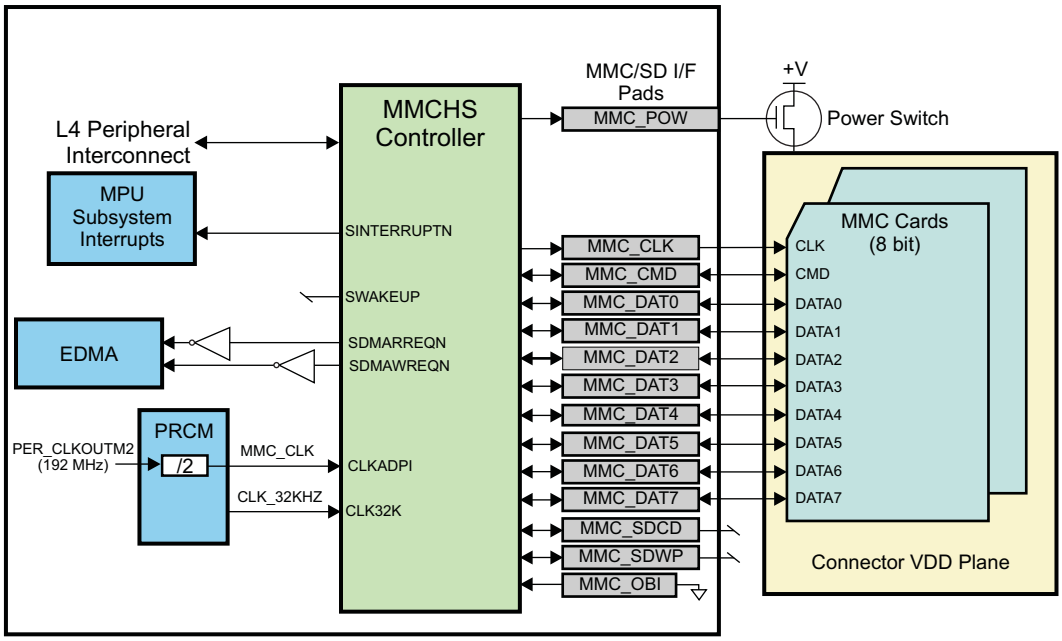

Figure 18-3. MMCHS Module MMC Application

18.2.1 MMCHS Connectivity Attributes

The general connectivity attributes for the three MMCHS modules are shown in Table 18-2.

Table 18-2. MMCHS Connectivity Attributes

Attributes	Type
Power Domain	Peripheral Domain
Clock Domain	PD_PER_L4LS_GCLK (OCP) PD_PER_MMC_FCLK (Func) CLK_32KHZ (Debounce)
Reset Signals	PER_DOM_RST_N
Idle/Wakeup Signals	Smart Idle
Interrupt Requests	1 interrupt per instance to MPU Subsystem (MMCSDxINT)
DMA Requests	2 DMA requests per instance to EDMA (SDTXEVTx, SDRXEVTx) (Active low, need to be inverted in glue logic)
Physical Address	L4 Peripheral slave port

Copyright © 2011, Texas Instruments Incorporated

18.2.2 MMCHS Clock and Reset Management

The MMCHS controller has separate bus interface and functional clocks. The debounce clock is created by dividing the 48-MHz (24 MHz @ OPP 50) clock in the PRCM by 2 and then dividing the resulting 24-MHz (12 MHz @ OPP50) clock by a fixed 732.4219 (366.2109 @ OPP 50) in the Control Module to get a 32-KHz clock. This clock is fed back into the PRCM for clock gating. (See the CLK32KDIVRATIO_CTRL register in Chapter 9, *Control Module*, for more details).

Table 18-3. MMCHS Clock Signals

Clock Signal	Max Freq	Reference / Source	Comments
CLK Interface clock	100 MHz	CORE_CLKOUTM4 / 2	pd_per_l4ls_gclk from PRCM
CLKADPI Functional clock	48 MHz	PER_CLKOUTM2 / 4	pd_per_mmc_fclk from PRCM
CLK32 Input de-bounce clock	32.768 KHz	CLK_24 / 732.4219	clk_32KHz from PRCM

18.2.3 MMCHS Pin List

The MMCHS interface pins are summarized in Table 18-4.

Table 18-4. MMCHS Pin List

Pin	Type	Description
MMC*x*_CLK	I/O	MMC/SD serial clock output
MMC*x*_CMD	I/O	MMC/SD command signal
MMC*x*_DAT0	I/O	MMC/SD data signal
MMC*x*_DAT1	I/O	MMC/SD data signal, SDIO interrupt input
MMC*x*_DAT2	I/O	MMC/SD data signal, SDIO read wait output
MMC*x*_DAT[7:3]	I/O	MMC/SD data signals
MMC*x*_POW	O	MMC/SD power supply control (MMCHS 0 only)
MMC*x*_SDCD	I	SD card detect (from connector)
MMC*x*_SDWP	I	SD write protect (from connector)
MMC*x*_OBI	I	MMC out of band interrupt

The direction of the data lines depends on the selected data transfer mode as summarized in Table 18-5.

Table 18-5. DAT Line Direction for Data Transfer Modes

	MMC/SD 1-bit mode	MMC/SD 4-bit mode	MMC/SD 8-bit mode	SDIO 1-bit mode	SDIO 4-bit mode
DAT[0]	I/O	I/O	I/O	I/O	I/O
DAT[1]	I[(1)]	I/O	I/O	I[(2)]	I/O or I[(2)]
DAT[2]	I[(1)]	I/O	I/O	I/O[(3)]	I/O or O[(3)]
DAT[3]	I[(1)]	I/O	I/O	I[(1)]	I/O
DAT[4]	I[(1)]	I[(1)]	I/O	I[(1)]	I[(1)]
DAT[5]	I[(1)]	I[(1)]	I/O	I[(1)]	I[(1)]
DAT[6]	I[(1)]	I[(1)]	I/O	I[(1)]	I[(1)]
DAT[7]	I[(1)]	I[(1)]	I/O	I[(1)]	I[(1)]

(1) Hi-Z state to avoid bus conflict.
(2) To support incoming interrupt from the SDIO card.
(3) To support read wait to the SDIO card. By default it is Input, Output only in read wait period.

Copyright © 2011, Texas Instruments Incorporated

The direction of the MMCHS data buffers are controlled by ADPDATDIROQ signals. ADPDATDIROQ[i] = 1 sets the corresponding DAT signal(s) in read position (input) and ADPDATDIROQ[i] = 0 sets the corresponding DAT signal(s) in write position (output). Additionally, the ADPDATDIRLS signals are provided (with opposite polarity) to control the direction of external level shifters. The value of these control signals for the various data modes are summarized in Table 18-6.

Table 18-6. ADPDATDIROQ and ADPDATDIRLS Signal States

	MMC/SD 1-bit mode	**MMC/SD 4-bit mode**	**MMC/SD 8-bit mode**	**SDIO 1-bit mode**	**SDIO 4-bit mode**
DAT[0]	ADPDATDIRLS[0] = 0 / 1 ADPDATDIROQ[0] = 1 / 0	ADPDATDIRLS[0] = 0 / 1 ADPDATDIROQ[0] = 1 / 0	ADPDATDIRLS[0] = 0 / 1 ADPDATDIROQ[0] = 1 / 0	ADPDATDIRLS[0] = 0 / 1	ADPDATDIRLS[0] = 0 / 1 ADPDATDIROQ[0] = 1 / 0
DAT[2]	ADPDATDIRLS[2] = 0 ADPDATDIROQ[2] = 1	ADPDATDIRLS[2] = 0 / 1 ADPDATDIROQ[2] = 1 / 0	ADPDATDIRLS[2] = 0 / 1 ADPDATDIROQ[2] = 1 / 0	ADPDATDIRLS[2] = 0 / 1 ADPDATDIROQ[2] = 1 / 0	ADPDATDIRLS[2] = 0 / 1 ADPDATDIROQ[2] = 1 / 0
DAT[1]	ADPDATDIRLS[1] = 0 ADPDATDIROQ[1] = 1	ADPDATDIRLS[1] = 0 / 1 ADPDATDIROQ[1] = 1 / 0	ADPDATDIRLS[1] = 0 / 1 ADPDATDIROQ[1] = 1 / 0	ADPDATDIRLS[1] = 0 ADPDATDIROQ[1] = 1	ADPDATDIRLS[1] = 0 / 1 ADPDATDIROQ[1] = 1 / 0
DAT[3]					
DAT[4]	ADPDATDIRLS[3] = 0 ADPDATDIROQ[3] = 1	ADPDATDIRLS[3] = 0 ADPDATDIROQ[3] = 1	ADPDATDIRLS[3] = 0 / 1 ADPDATDIROQ[3] = 1 / 0	ADPDATDIRLS[3] = 0 ADPDATDIROQ[3] = 1	ADPDATDIRLS[3] = 0 ADPDATDIROQ[3] = 1
DAT[5]					
DAT[6]					
DAT[7]					

ADPDATIRLSx = 0 for input and 1 for output — these signals are not pinned out on this device.

ADPDATIROQx = 1 for output and 1 for input.

Grayed cells indicate that the data line is not used in the selected transfer mode.

18.3 Functional Description

One MMC/SD/SDIO host controller can support one MMC memory card, one SD card, or one SDIO card.

Other combinations (for example, two SD cards, one MMC card, and one SD card) are not supported through a single controller.

18.3.1 MMC/SD/SDIO Functional Modes

18.3.1.1 MMC/SD/SDIO Connected to an MMC, an SD Card, or an SDIO Card

Figure 18-4 shows the MMC/SD/SDIO1 and MMC/SD/SDIO2 host controllers connected to an MMC, an SD, or an SDIO card and its related external connections.

Figure 18-4. MMC/SD1/2 Connectivity to an MMC/SD Card

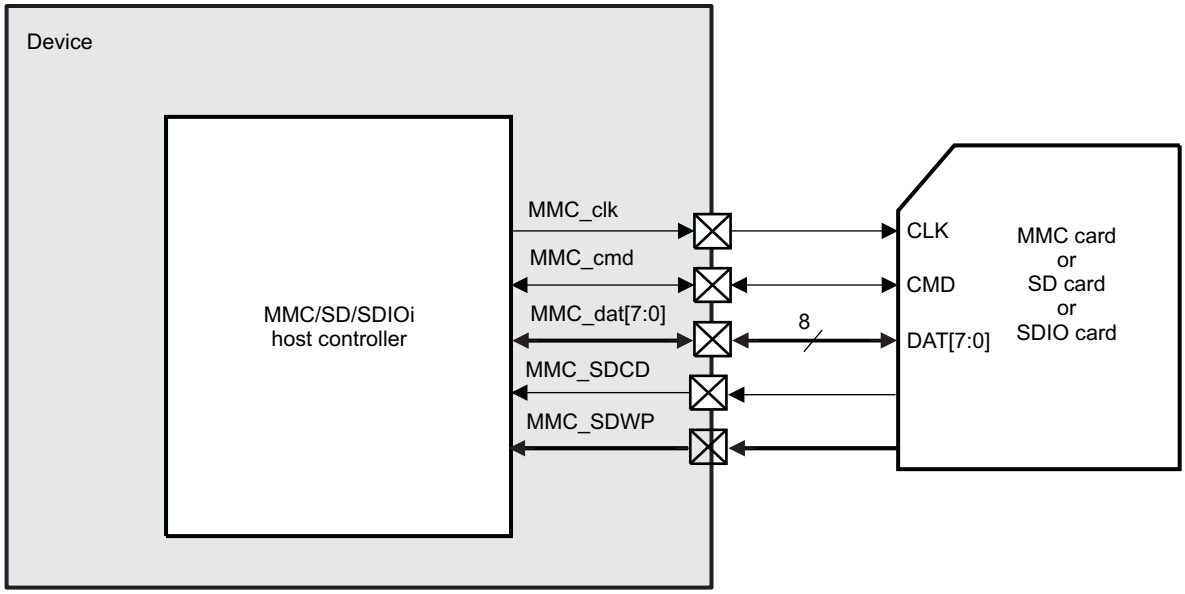

Figure 18-5. MMC/SD0 Connectivity to an MMC/SD Card

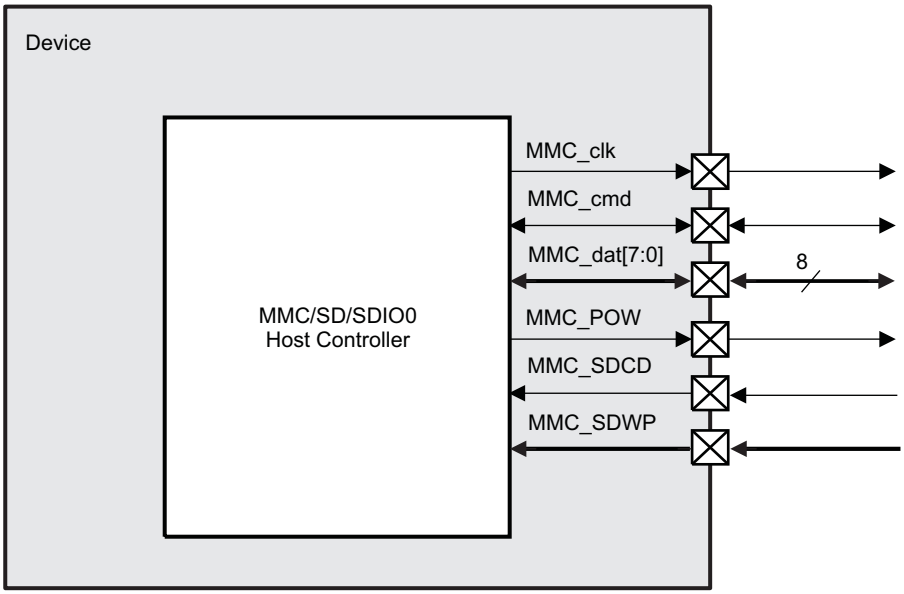

Copyright © 2011, Texas Instruments Incorporated

Figure 18-5 shows the MMC/SD/SDIO0 host controller connected to an MMC, SD, or SDIO card and its related external connections. Note that MMC/SD/SDIO0 uses the same signals as MMC/SD/SDIO1 and 2 but adds MMC_POW.

Copyright © 2011, Texas Instruments Incorporated

The following MMC/SD/SDIO controller pins are used

- **MMC_CMD** This pin is used for two-way communication between the connected card and the MMC/SD/SDIO controller. The MMC/SD/SDIO controller transmits commands to the card and the memory card drives responses to the commands on this pin.
- **MMC_DAT7-0** Depending on which type of card you are using, you may need to connect 1, 4, or 8 data lines. The number of DAT pins (the data bus width) is set by the Data Transfer Width (DTW) bit in the MMC control register (SD_HCTL). For more information, see the registers section of this document.
- **MMC_CLK** This pin provides the clock to the memory card from the MMC/SD controller.
- **MMC_POW** Used for MMC/SD card's cards on/off power supply control. When high, denotes power-on condition.
- **MMC_SDCD** This input pin serves as the MMC/SD/SDIO carrier detect. This signal is received from a mechanical switch on the slot.
- **MMC_SDWP** This input pin is used for the SD/SDIO card's write protect. This signal is received from a mechanical protect switch on the slot (system dependant). Applicable only for SD and SDIO cards that have a mechanical sliding tablet on the side of the card.

  Note: The MMC_CLK pin functions as an output but must be configured as an I/O to internally loopback the clock to time the inputs.

Table 18-7 provides a summary of these pins.

Table 18-7. MMC/SD/SDIO Controller Pins and Descriptions

Pin	Type	1-Bit Mode	4-Bit Mode	8-Bit Mode	Reset Value
MMC_CLK[1]	O	Clock Line	Clock Line	Clock Line	High impedance
MMC_CMD	I/O	Command Line	Command Line	Command Line	High impedance
MMC_DAT0	I/O	Data Line 0	Data Line 0	Data Line 0	0
MMC_DAT1	I/O	(not used)	Data Line 1	Data Line 1	0
MMC_DAT2	I/O	(not used)	Data Line 2	Data Line 2	0
MMC_DAT3	I/O	(not used)	Data Line 3	Data Line 3	0
MMC_DAT4	I/O	(not used)	(not used)	Data Line 4	0
MMC_DAT5	I/O	(not used)	(not used)	Data Line 5	0
MMC_DAT6	I/O	(not used)	(not used)	Data Line 6	0
MMC_DAT7	I/O	(not used)	(not used)	Data Line 7	0

(1) The MMC_CLK pin functions as an output but must be configured as an I/O to internally loopback the clock to time the inputs.

18.3.1.2 Protocol and Data Format

The bus protocol between the MMC/SD/SDIO host controller and the card is message-based. Each message is represented by one of the following parts:

Command: A command starts an operation. The command is transferred serially from the \MMC/SD/SDIO host controller to the card on the mmc_cmd line.

Response: A response is an answer to a command. The response is sent from the card to the MMC/SD/SDIO host controller. It is transferred serially on the mmc_cmd line.

Data: Data are transferred from the MMC/SD/SDIO host controller to the card or from a card to the MMC/SD/SDIO host controller using the DATA lines.

Busy: The mmc_dat0 signal is maintained low by the card as far as it is programming the data received.

CRC status: CRC result is sent by the card through the mmc_dat0 line when executing a write transfer. In the case of transmission error, occurring on any of the active data lines, the card sends a negative CRC status on mmc_dat0. In the case of successful transmission, over all active data lines, the card sends a positive CRC status on mmc_dat0 and starts the data programming procedure.

Copyright © 2011, Texas Instruments Incorporated

18.3.1.2.1 Protocol

There are two types of data transfer:

- Sequential operation
- Block-oriented operation

There are specific commands for each type of operation (sequential or block-oriented). See the *Multimedia Card System Specification*, the *SD Memory Card Specifications*, and the *SDIO Card Specification, Part E1* for details about commands and programming sequences supported by the MMC, SD, and SDIO cards.

CAUTION

Stream commands are supported only by MMC cards.

Figure 18-6 and Figure 18-7 show how sequential operations are defined. Sequential operation is only for 1-bit transfer and initiates a continuous data stream. The transfer terminates when a stop command follows on the mmc_cmd line.

Figure 18-6. Sequential Read Operation (MMC Cards Only)

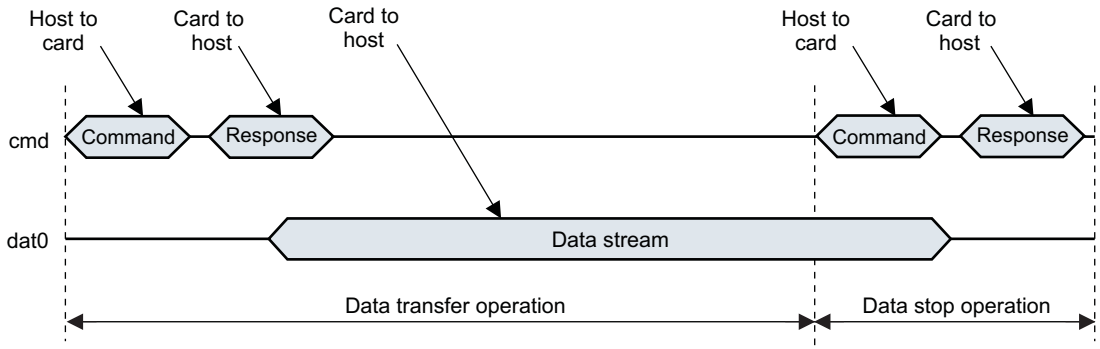

Figure 18-7. Sequential Write Operation (MMC Cards Only)

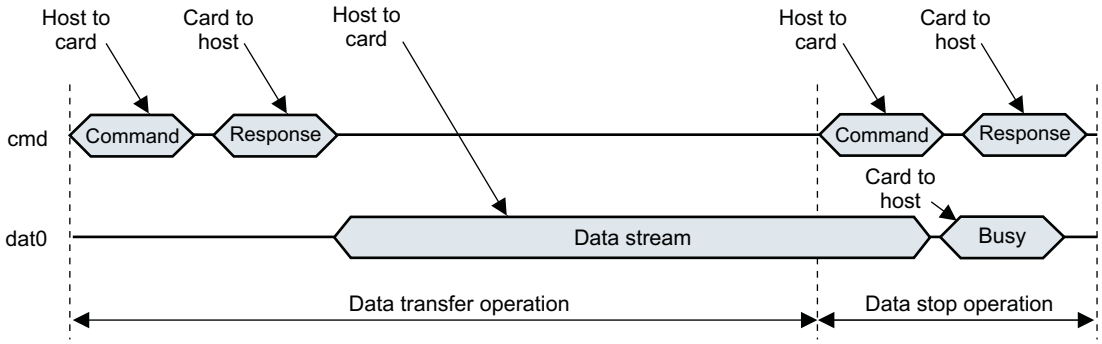

Copyright © 2011, Texas Instruments Incorporated

Figure 18-8 and Figure 18-9 show how multiple block-oriented operations are defined. A multiple block-oriented operation sends a data block plus CRC bits. The transfer terminates when a stop command follows on the mmc_cmd line. These operations are available for all kinds of cards.

Figure 18-8. Multiple Block Read Operation (MMC Cards Only)

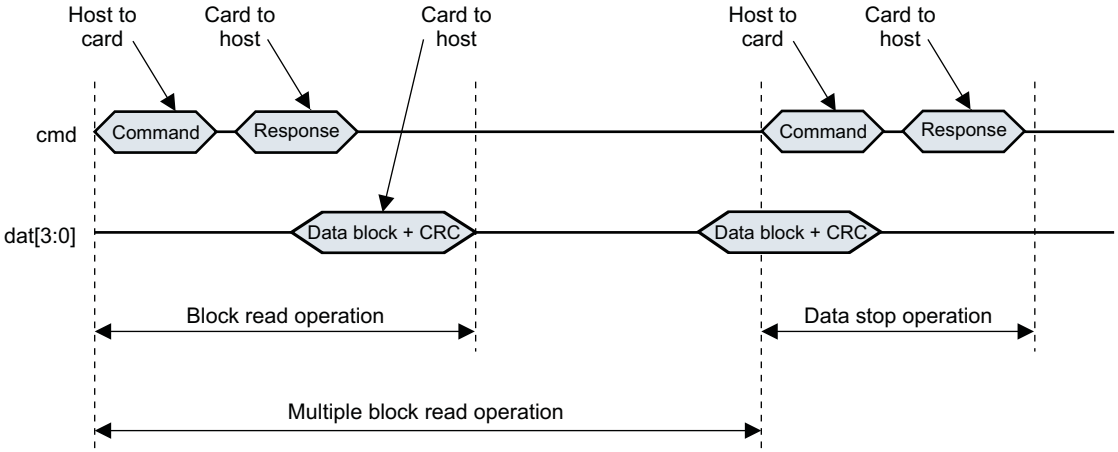

Figure 18-9. Multiple Block Write Operation (MMC Cards Only)

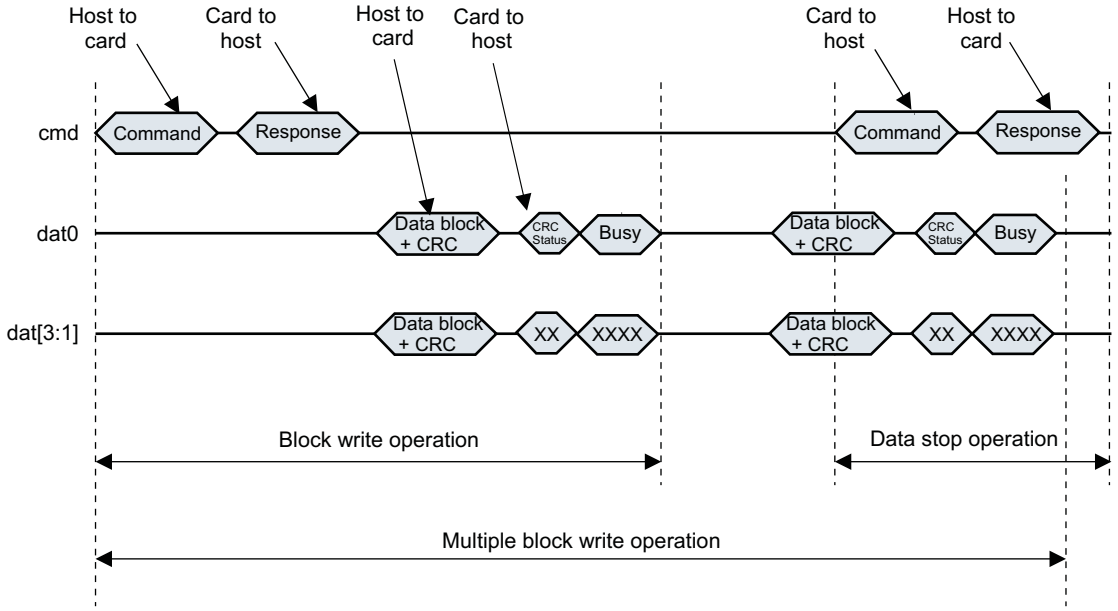


NOTE:

1. The card busy signal is not always generated by the card; the previous examples show a particular case.
2. It is the software's responsibility to do a software reset after a data timeout to ensure that mmc_clk is stopped. The software reset is done by setting bit 26 in the SD_SYSCTL register to 1.
3. For multiblock transfer, and especially for MMC cards, you can abort a transfer without using a stop command. Use a CMD23 before a data transfer to define the number of blocks that will be transferred, then the transfer stops automatically after the last block (provided the MMC card supports this feature).

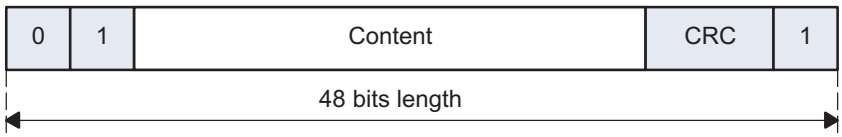
Copyright © 2011, Texas Instruments Incorporated

18.3.1.2.2 Data Format

Coding Scheme for Command Token

Command packets always start with 0 and end with 1. The second bit is a transmitter bit1 for a host command. The content is the command index (coded by 6 bits) and an argument (for example, an address), coded by 32 bits. The content is protected by 7-bit CRC checksum (see Figure 18-10).

Figure 18-10. Command Token Format



Coding Scheme for Response Token

Response packets always start with 0 and end with a 1. The second bit is a transmitter bit0 for a card response. The content is different for each type of response (R1, R2, R3, R4, R5, and R6) and the content is protected by 7-bit CRC checksum. Depending on the type of commands sent to the card, the SD_CMD register must be configured differently to avoid false CRC or index errors to be flagged on command response (see Table 18-8). For more details about response types, see the *Multimedia Card System Specification*, the *SD Memory Card Specification*, or the *SDIO Card Specification*.

Table 18-8. Response Type Summary[(1)]

Response Type SD_CMD[17:16] RSP_TYPE	Index Check Enable SD_CMD[20] CICE	CRC Check Enable SD_CMD[19] CCCE	Name of Response Type
00	0	0	No Response
01	0	1	R2
10	0	0	R3 (R4 for SD cards)
10	1	1	R1, R6, R5 (R7 for SD cards)
11	1	1	R1b, R5b

(1) The MMC/SD/SDIO host controller assumes that both clocks may be switched off, whatever the value set in the SD_SYSCONFIG[9:8] CLOCKACTIVITY bit.

Figure 18-11 and Figure 18-12 depict the 48-bit and 136-bit response packets.

Figure 18-11. 48-Bit Response Packet (R1, R3, R4, R5, R6)

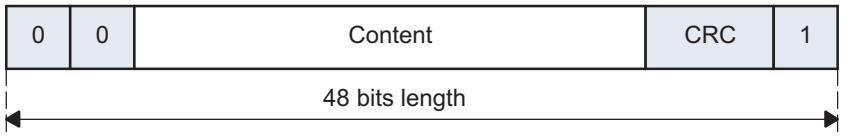


Figure 18-12. 136-Bit Response Packet (R2)

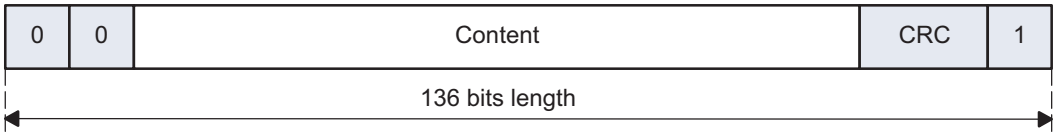

Copyright © 2011, Texas Instruments Incorporated

Coding Scheme for Data Token

Data tokens always start with 0 and end with 1 (see Figure 18-13, Figure 18-14, Figure 18-15, and Figure 18-16).

Figure 18-13. Data Packet for Sequential Transfer (1-Bit)

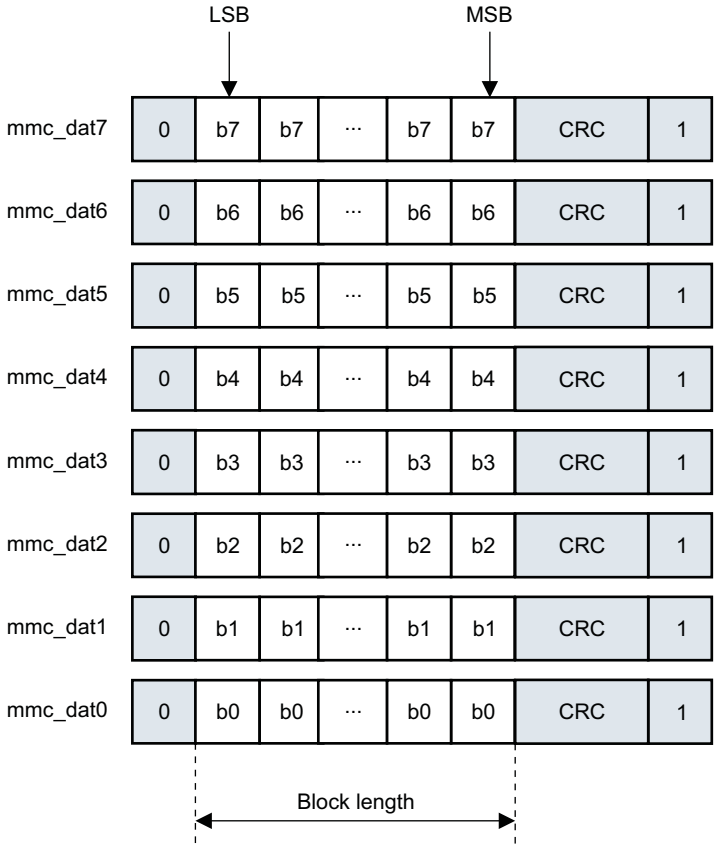
Figure 18-16. Data Packet for Block Transfer (8-Bit)



18.3.2 Resets

18.3.2.1 Hardware Reset

The module is reinitialized by the hardware.

The SD_SYSSTATUS[0] RESETDONE bit can be monitored by the software to check if the module is ready-to-use after a hardware reset.

This hardware reset signal has a global reset action on the module. All configuration registers and all state machines are reset in all clock domains.

This hardware reset signal has a global reset action on the module. All configuration registers and all state-machines are reset in all clock domains.

18.3.2.2 Software Reset

The module is reinitialized by software through the SD_SYSCONFIG[1] SOFTRESET bit. This bit has the same action on the module logic as the hardware signal except for:

- Debounce logic
- SD_PSTATE, SD_CAPA, and SD_CUR_CAPA registers (see corresponding register descriptions)

The SOFTRESET bit is active high. The bit is automatically reinitialized to 0 by the hardware. The SD_SYSCTL[24] SRA bit has the same action as the SOFTRESET bit on the design.

The SD_SYSSTATUS[0] RESETDONE bit can be monitored by the software to check if the module is ready-to-use after a software reset.

Copyright © 2011, Texas Instruments Incorporated

Moreover, two partial software reset bits are provided:

- SD_SYSCTL[26] SRD bit
- SD_SYSCTL[25] SRC bit

These two reset bits are useful to reinitialize data or command processes respectively in case of line conflict. When set to 1, a reset process is automatically released when the reset completes:

- The SD_SYSCTL[26] SRD bit resets all finite state-machines and status management that handle data transfers on both the interface and functional side.
- The SD_SYSCTL[25] SRC bit resets all finite state-machines and status management that handle command transfers on both the interface and functional side.

NOTE: If **any** of the clock inputs are not present for the MMC/SD/SDIO peripheral, the software reset will not complete.

18.3.3 Power Management

The MMC/SD/SDIO host controller can enter into different modes and save power:

- Normal mode
- Idle mode

The two modes are mutually exclusive (the module can be in normal mode or in idle mode). The MMC/SD/SDIO host controller is compliant with the PRCM module handshake protocol. When the MMC/SD/SDIO power domain is off, the only way to wake up the power domain and different MMC/SD/SDIO clocks is to monitor the mmc_dat1 input pin state via a different GPIO line for each MMC/SD/SDIO interface.

18.3.3.1 Normal Mode

The autogating of interface and functional clocks occurs when the following conditions are met:

- The SD_SYSCONFIG[0] AUTOIDLE bit is set to 1.
- There is no transaction on the MMC interface.

The autogating of interface and functional clocks stops when the following conditions are met:

- A register access occurs through the L3 (or L4) interconnect.
- A wake-up event occurs (an interrupt from a SDIO card).
- A transaction on the MMC/SD/SDIO interface starts.

Then the MMC/SD/SDIO host controller enters in low-power state even if SD_SYSCONFIG[0] AUTOIDLE is cleared to 0. The functional clock is internally switched off and only interconnect read and write accesses are allowed.

18.3.3.2 Idle Mode

The clocks provided to MMC/SD/SDIO are switched off upon a PRCM module request. They are switched back upon module request. The MMC/SD/SDIO host controller complies with the PRCM module handshaking protocol:

- Idle request from the system power manager
- Idle acknowledgment from the MMC/SD/SDIO host controller
- Wake-up request from the MMC/SD/SDIO host controller

The idle acknowledgment varies according to the SD_SYSCONFIG[4:3] SIDLEMODE bit field:

- 0: Force-idle mode. The MMC/SD/SDIO host controller acknowledges the system power manager request unconditionally.
- 1h: No-idle mode. The MMC/SD/SDIO host controller ignores the system power manager request and behaves normally as if the request was not asserted.
- 2h: Smart-idle mode. The MMC/SD/SDIO host controller acknowledges the system power manager

Copyright © 2011, Texas Instruments Incorporated

request according to its internal state.

- 3h: Smart-idle wake-up-capable mode. The MMC/SD/SDIO host controller acknowledges the system power manager request according to its internal state. However, the module may generate wake-up events when in idle state (related to IRQ or DMA requests)

During the smart-idle mode period, the MMC/SD/SDIO host controller acknowledges that the OCP and Functional clocks may be switched off whatever the value set in the SD_SYSCONFIG[9:8] CLOCKACTIVITY field.

18.3.3.3 Transition from Normal Mode to Smart-Idle Mode

Smart-idle mode is enabled when the SD_SYSCONFIG[4:3] SIDLEMODE bit field is set to 2h or 3h. The MMC/SD/SDIO host controller goes into idle mode when the PRCM issues an idle request, according to its internal activity. The MMC/SD/SDIO host controller acknowledges the idle request from the PRCM after ensuring the following:

- The current multi/single-block transfer is completed.
- Any interrupt or DMA request is asserted.
- There is no card interrupt on the SD_dat1 signal.

As long as the MMC/SD/SDIO controller does not acknowledge the idle request, if an event occurs, the MMC/SD/SDIO host controller can still generate an interrupt or a DMA request. In this case, the module ignores the idle request from the PRCM.

As soon as the MMC/SD/SDIO controller acknowledges the idle request from the PRCM:

- If Smart-Idle modethe module does not assert any new interrupt or DMA request
- If Smart-Idle wake-up-capable modethe module may generate wake-up events related to interrupt or DMA request.

18.3.3.4 Transition from Smart-Idle Mode to Normal Mode

The MMC/SD/SDIO host controller detects the end of the idle period when the PRCM deasserts the idle request. For the wake-up event, there is a corresponding interrupt status in the SD_STAT register. The MMC/SD/SDIO host controller operates the conversion between wake-up and interrupt (or DMA request) upon exit from smart-idle mode if the associated enable bit is set in the SD_ISE register.

Interrupts and wake-up events have independent enable/disable controls, accessible through the SD_HCTL and SD_ISE registers. The overall consistency must be ensured by software.

The interrupt status register SD_STAT is updated with the event that caused the wake-up in the CIRQ bit when the SD_IE[8] CIRQ_ENABLE associated bit is enabled. Then, the wake-up event at the origin of the transition from smart-idle mode to normal mode is converted into its corresponding interrupt or DMA request. (The SD_STAT register is updated and the status of the interrupt signal changes.)

When the idle request from the PRCM is deasserted, the module switches back to normal mode. The module is fully operational.

18.3.3.5 Force-Idle Mode

Force-idle mode is enabled when the SD_SYSCONFIG[4:3] SIDLEMODE bit field is cleared to 0. Force-idle mode is an idle mode where the MMC/SD/SDIO host controller responds unconditionally to the idle request from the PRCM. Moreover, in this mode, the MMC/SD/SDIO host controller unconditionally deasserts interrupts and DMA request lines are asserted.

The transition from normal mode to force-idle mode does not affect the bits of the SD_STAT register. In force-idle mode, the interrupt and DMA request lines are deasserted. Interface Clock (OCP) and functional clock (CLKADPI) can be switched off.

Copyright © 2011, Texas Instruments Incorporated

CAUTION

In Force-ilde mode, an idle request from the PRCM during a command or a data transfer can lead to an unexpected and unpredictable result. When the module is idle, any access to the module generates an error as long as the OCP clock is alive.

The module exits the force-idle mode when the PRCM deassertes the idle request. Then the module switches back to normal mode. The module is fully operational. Interrupt and DMA request lines are optionally asserted one clock cycle later.

18.3.3.6 Local Power Management

Table 18-9 describes power-management features available for the MMC/SD/SDIO modules.

Table 18-9. Local Power Management Features

Feature	Registers	Description
Clock Auto Gating	SD_SYSCONFIG AUTOIDLE bit	This bit allows a local power optimization inside module, by gating the OCP clock upon the interface activity or gating the CLKADPI clock upon the internal activity.
Slave Idle Modes	SD_SYSCONFIG SIDLEMODE bit	Force-idle, No-idle, and Smart-idle modes
Clock Activity	SD_SYSCONFIG CLOCKACTIVITY bit	Please see Table 18-10 for configuration details.
Master Standby Modes	SD_SYSCONFIG STANDYBYMODE bit	Force-idle, No-idle, and Smart-idle modes
Global Wake-Up Enable	SD_SYSCONFIG ENAWAKEUP bit	This bit enables the wake-up feature at module level.
Wake-Up Sources Enable	SD_HCTL register	This register holds one active high enable bit per event source able to generate wake-up signal.

Table 18-10. Clock Activity Settings

CLOCKACTIVITY Values	Clock State When Module is in IDLE State		Features Available when Module is in IDLE State	Wake-Up Events
	OCP Clock	CLKADPI		
00	OFF	OFF	None	Card Interrupt
10	OFF	ON	None	
01	ON	OFF	None	
11	ON	ON	All	

CAUTION

The PRCM module has no hardware means of reading CLOCKACTIVITY settings. Thus, software must ensure consistent programming between the CLOCKACTIVITY and MMC clock PRCM control bits.

Copyright © 2011, Texas Instruments Incorporated

18.3.4 Interrupt Requests

Several internal module events can generate an interrupt. Each interrupt has a status bit, an interrupt enable bit, and a signal status enable:

- The status of each type of interrupt is automatically updated in the SD_STAT register; it indicates which service is required.
- The interrupt status enable bits of the SD_IE register enable/disable the automatic update of the SD_STAT register on an event-by-event basis.
- The interrupt signal enable bits of the SD_ISE register enable/disable the transmission of an interrupt request on the interrupt line MMC_IRQ (from the MMC/SD/SDIOi host controller to the MPU subsystem interrupt controller) on an event-by-event basis.

If an interrupt status is disabled in the SD_IE register, then the corresponding interrupt request is not transmitted, and the value of the corresponding interrupt signal enable in the SD_ISE register is ignored.

When an interrupt event occurs, the corresponding status bit is automatically set to 1 (the MMC/SD/SDIO host controller updates the status bit) in the SD_STAT register. If later a mask is applied on the interrupt in the SD_ISE register, the interrupt request is deactivated.

When the interrupt source has not been serviced, if the interrupt status is cleared in the SD_STAT register and the corresponding mask is removed from the SD_ISE register, the interrupt status is not asserted again in the SD_STAT register and the MMC/SD/SDIOi host controller does not transmit an interrupt request.

CAUTION

If the buffer write ready interrupt (BWR) or the buffer read ready only interrupt (BRR) are not serviced and are cleared in the SD_STAT register, and the corresponding mask is removed, then the MMC/SD/SDIOi host controller will wait for the service of the interrupt without updating the status SD_STAT or transmitting an interrupt request.

Table 18-11 lists the event flags, and their mask, that can cause module interrupts.

Table 18-11. Events

Event Flag	Event Mask	Map To	Description
SD_STAT[29] BADA	SD_IE[29] BADA_ENABLE	MMC_IRQ	Bad Access to Data space. This bit is set automatically to indicate a bad access to buffer when not allowed. This bit is set during a read access to the data register (SD_DATA) while buffer reads are not allowed (SD_PSTATE[11] BRE=0). This bit is set during a write access to the data register (SD_DATA) while buffer writes are not allowed (SD_STATE[10] BWE=0)
SD_STAT[28] CERR	SD_IE[28] CERR_ENABLE	MMC_IRQ	Card Error. This bit is set automatically when there is at least one error in a response of type R1, R1b, R6, R5 or R5b. Only bits referenced as type E(error) in status field in the response can set a card status error. An error bit in the response is flagged only if corresponding bit in card status response errros SD_CSRE is set. There is not card detection for auto CMD12 command.
SD_STAT[25] ADMAE	SD_IE[25] ADMAE_ENABLE	MMC_IRQ	AMDA error. This bit is set when the host controller detects errors during ADMA based data transfer. The stat of the ADMA at an error occurrence is saved in the ADMA Error Status Register. In addition, the host controller generates this interrupt when it detects invalid descriptor data (Valid=0) at teh ST_FDS state.
SD_STAT[24] ACE	SD_IE[24] ACE_ENABLE	MMC_IRQ	Auto CMD12 error. This bit is set automatically when one of the bits in Auto CMD12 Error status register has changed from 0 to 1
SD_STAT[22] DEB	SD_IE[22] DEB_ENABLE	MMC_IRQ	Data End Bit error. This bit is set automatically when detecting a 0 at the end bit position of read data on DAT line or at the end position of the CRC status in write mode.

Copyright © 2011, Texas Instruments Incorporated

Table 18-11. Events (continued)

Event Flag	Event Mask	Map To	Description
SD_STAT[21] DCRC	SD_IE[21] DCRC_ENABLE	MMC_IRQ	Data CRC error. This bit is set automatically when there is a CRC16 error in the data phase response following a block read command or if there is a 3-bit CRC status different of a position "010" token during a block write command.
SD_STAT[20] DTO	SD_IE[20] DTO_ENABLE	MMC_IRQ	Data Timeout error. This bit is set automatically according to the following conidtions: A) busy timeout for R1b, R5b response. B) busty timeout after write CRC status. C) write CRC status timeout, or D) read data timeout.
SD_STAT[19] CIE	SD_IE[19] CIE_ENABLE	MMC_IRQ	Command Index Error. This bit is set automatically when response index differs from corresponding command index previously emitted. The check is enabled through SD_CMD[20] CICE bit.
SD_STAT[18] CEB	SD_IE[18] CEB_ENABLE	MMC_IRQ	Command End Bit error. This bit is set automatically when detecting a 0 at the end bit position of a command response.
SD_STAT[17] CCRC	SD_IE[17] CCRC_ENABLE	MMC_IRQ	Command CRC error. This bit is set automatically when there is a CRC7 error in the command response. CRC check is enabled through the SD_CMD[19] CCCE bit.
SD_STAT[16] CTO	SD_IE[16] CTO_ENABLE	MMC_IRQ	Command Timeout error. This bit is set automatically when no response is received within 64 clock cycles from the end bit of the command. For commands the reply within 5 clock cycles, the timeout is still detected at 64 clock cycles.
SD_STAT[15] ERRI	SD_IE[15] ERRI_ENABLE	MMC_IRQ	Error Interrupt. If any of the bits in the Error Interrupt Status register (SD_STAT[24:15]) are set, the this bit is set to 1.
SD_STAT[10] BSR	SD_IE[10] BSR_ENABLE	MMC_IRQ	Boot Status Receieved interrupt. This bit is set automatically when SD_CON[18] BOOT_CF0 is set to 1 or 2h and boot status is received on the dat0 line. This interrupt is only used for MMC cards.
SD_STAT[8] CIRQ	SD_IE[8] CIRQ_ENABLE	MMC_IRQ	Card Interrupt. This bit is only used for SD, SDIO, and CE-ATA cards. In 1-bit mode, interrupt source is asynchronous (can be a source of asynchronous wake-up). In 4-bit mode, interrupt source is sampled during the interrupt cycle. In CE-ATA mode, interrupt source is detected when the card drive CMD line to zero during one cycle after data transmission end.
SD_STAT[5] BRR	SD_IE[5] BRR_ENABLE	MMC_IRQ	Buffer Read ready. This bit is set automatically during a read operation to the card when one block specified by SD_BLK[10:0] BLEN is completely written in the buffer. It indicates that the memory card has filled out the buffger and the local host needs to empty the buffer by reading it.
SD_STAT[4] BWR	SD_IE[4] BWR_ENABLE	MMC_IRQ	Buffer Write ready. This bit is automatically set during a write operation to the card when the host can write a complete block as specified by SD_BLK[10:0] BLEN. It indicates that the memory card has emptied one block from the bugger and the local host is able to write one block of data into the buffer.
SD_STAT[3] DMA	SD_IE[3] DMA_ENABLE	MMC_IRQ	DMA interrupt. This status is set when an interrupt is required in the AMDA instruction and after the data transfer is complete.
SD_STAT[2] BGE	SD_IE[2] BGE_ENABLE	MMC_IRQ	Block Gap event. When a stop at block gap is requested (SD_HCTL[16] SBGR), this bit is automatically set when transaction is stopped at the block gap during a read or write operation.
SD_STAT[1] TC	SD_IE[1] TC_ENABLE	MMC_IRQ	Transfer completed. This bit is always set when a read/write transfer is completed or between two blocks when the transfer is stopped due to a stop at block gap requesd (SD_HCTL[16 SBGR). In read mode this bit is automatically set on completion of a read transfer (SD_PSTATE[9] RTA). In write mode, this bit is automatically set on completion of the DAT line use (SD_PSTATE[2] DLA).
SD_STAT[0] CC	SD_IE[0] CC_ENABLE	MMC_IRQ	Command complete. This bit is set when a 1-to-0 transition occurs in the register command inhibit (SD_PSTATE[0] CMDI). If the command is a type for which no response is expected, then the command complete interrupt is generated at the end of the command. A command timeout error (SD_STAT[16] CTO) has higher priority than command complete (SD_STAT[0] CC). If a response is expected but none is received, the a Command Timeout error is detected and signaled instead of the Command Complete interrupt.

Copyright © 2011, Texas Instruments Incorporated

18.3.4.1 Interrupt-Driven Operation

An interrupt enable bit must be set in the SD_IE register to enable the module internal source of interrupt.

When an interrupt event occurs, the single interrupt line is asserted and the LH must:

- Read the SD_STAT register to identify which event occurred.
- Write 1 into the corresponding bit of the SD_STAT register to clear the interrupt status and release the interrupt line (if a read is done after this write, this would return 0).

NOTE: In the SD_STAT register, Card Interrupt (CIRQ) and Error Interrupt (ERRI) bits cannot be cleared.

The SD_STAT[8] CIRQ status bit must be masked by disabling the SD_IE[8] CIRQ_ENABLE bit (cleared to 0), then the interrupt routine must clear SDIO interrupt source in SDIO card common control register (CCCR).

The SD_STAT[15] ERRI bit is automatically cleared when all status bits in SD_STAT[31:16] are cleared.

18.3.4.2 Polling

When the interrupt capability of an event is disabled in the SD_ISE register, the interrupt line is not asserted:

- Software can poll the status bit in the SD_STAT register to detect when the corresponding event occurs.
- Writing 1 into the corresponding bit of the SD_STAT register clears the interrupt status and does not affect the interrupt line state.

NOTE: Please see the note in Section 18.3.4.1 concerning CIRQ and ERRI bits clearing.

18.3.5 DMA Modes

The device supports DMA slave mode only. In this case, the controller is slave on DMA transaction managed by two separated requests (SDMAWREQN and SDMARREQN)

18.3.5.1 DMA Slave Mode Operations

The MMC/SD/SDIO controller can be interfaced with a DMA controller. At system level, the advantage is to discharge the local host (LH) of the data transfers. The module does not support wide DMA access (above 1024 bytes) for SD cards as specified in the *SD Card Specification*and *SD Host Controller Standard Specification*.

The DMA request is issued if the following conditions are met:

- The SD_CMD[0] DE bit is set to 1 to trigger the initial DMA request (the write must be done when running the data transfer command).
- A command was emitted on the SD_cmd line.
- There is enough space in the buffer of the MMC/SD/SDIO controller to write an entire block (BLEN writes).

Copyright © 2011, Texas Instruments Incorporated

18.3.5.1.1 DMA Receive Mode

In a DMA block read operation (single or multiple), the request signal SDMARREQN is asserted to its active level when a complete block is written in the buffer. The block size transfer is specified in the SD_BLK[10:0] BLEN field.

The SDMARREQN signal is deasserted to its inactive level when the sDMA has read one single word from the buffer. Only one request is sent per block; the DMA controller can make a 1-shot read access or several DMA bursts, in which case the DMA controller must manage the number of burst accesses, according to block size BLEN field.

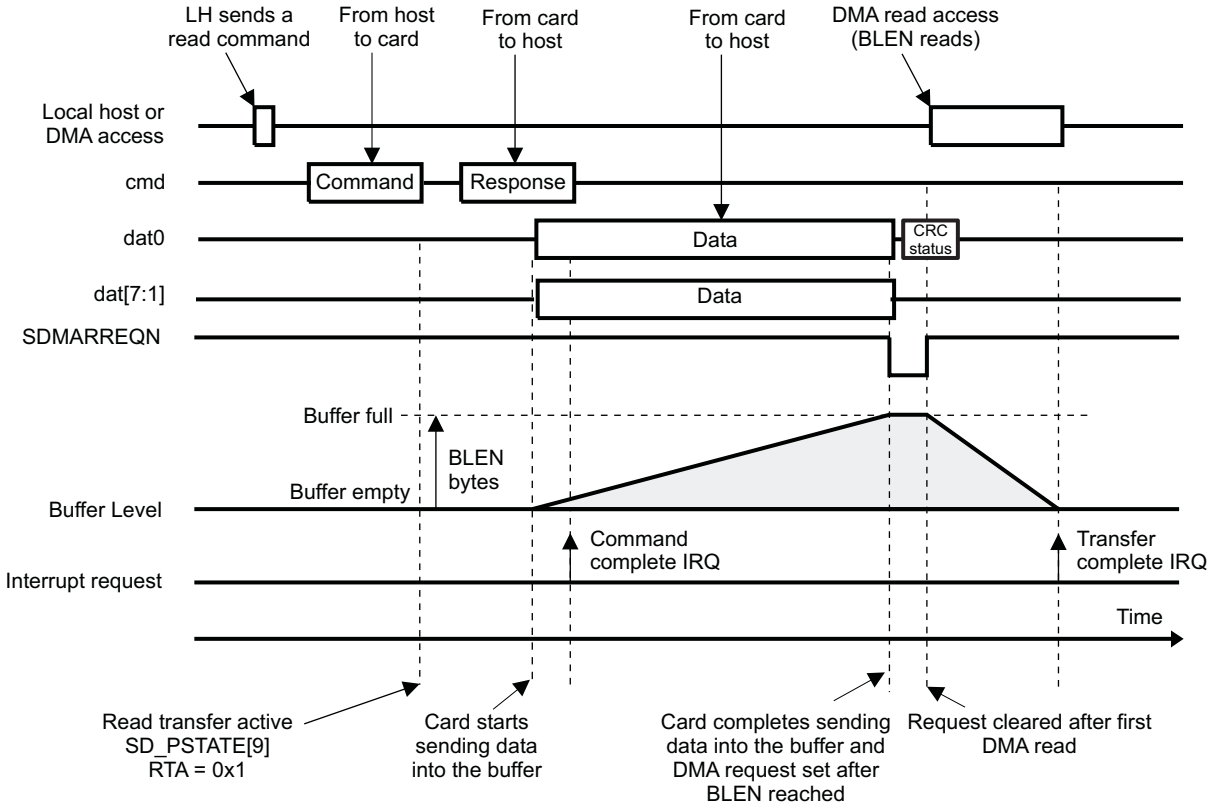
New DMA requests are internally masked if the sDMA has not read exactly BLEN bytes and a new complete block is not ready. As DMA accesses are in 32-bit, then the number of sDMA read is Integer(BLEN/4)+1.

The receive buffer never overflows. In multiple block transfers for block size above 512 bytes, when the buffer gets full, the MMC_CLK clock signal (provided to the card) is momentarily stopped until the sDMA or the MPU performs a read access, which reads a complete block in the buffer.

Figure 18-17 provides a summary:

- DMA transfer size = BLEN buffer size in one shot or by burst
- One DMA request per block

Figure 18-17. DMA Receive Mode



Copyright © 2011, Texas Instruments Incorporated

18.3.5.1.2 DMA Transmit Mode

In a DMA block write operation (single or multiple), the request signal SDMAWREQN is asserted to its active level when a complete block is to be written to the buffer. The block size transfer is specified in the SD_BLK[10:0] BLEN field.

The SDMAWREQN signal is deasserted to its inactive level when the sDMA has written one single word to the buffer.

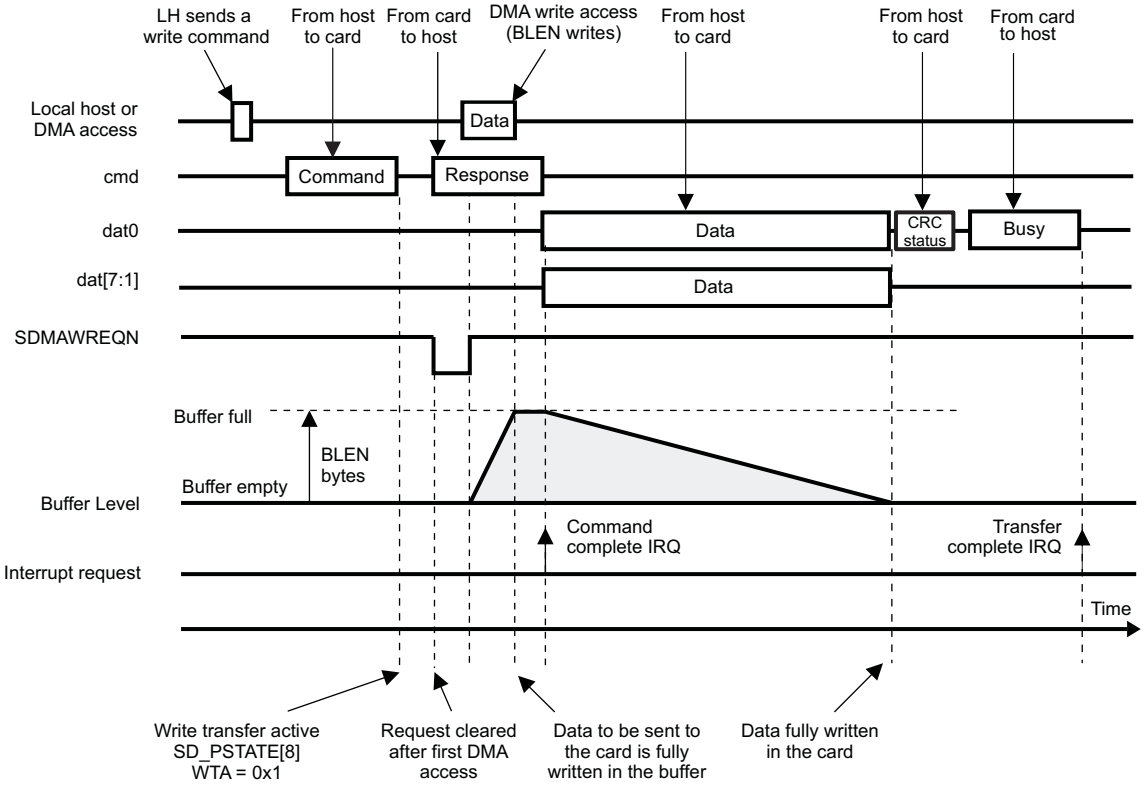
Only one request is sent per block; the DMA controller can make a 1-shot write access or multiple write DMA bursts, in which case the DMA controller must manage the number of burst accesses, according to block size BLEN field.

New DMA requests are internally masked if the sDMA has not written exactly BLEN bytes (as DMA accesses are in 32-bit, then the number of sDMA read is Integer(BLEN/4)+1) and if there is not enough memory space to write a complete block in the buffer.

Figure 18-18 provides a summary:

- DMA transfer size = BLEN buffer size in one shot or by burst
- One DMA request per block

Figure 18-18. DMA Transmit Mode



Copyright © 2011, Texas Instruments Incorporated

18.3.6 Mode Selection

The MMC/SD/SDIO host controller can be use in two modes, MMC and SD/SDIO modes. It has been designed to be the most transparent with the type of card. The type of the card connected is differentiated by the software initialization procedure.

Software identifies the type of card connected during software initialization. For each given card type, there are corresponding commands. Some commands are not supported by all cards. See the *Multimedia Card System Specification*, the *SD Memory Card Specifications*, and the *SDIO Card Specification, Part E1* for more details.

The purpose of the module is to transfer commands and data, to whatever card is connected, respecting the protocol of the connected card. Writes and reads to the card must respect the appropriate protocol of that card.

18.3.7 Buffer Management

18.3.7.1 Data Buffer

The MMC/SD/SDIO host controller uses a data buffer. This buffer transfers data from one data bus (Interconnect) to another data bus (SD, SDIO, or MMC card bus) and vice versa.

The buffer is the heart of the interface and ensures the transfer between the two interfaces (L4 and the card). To enhance performance, the data buffer is completed by a prefetch register and a post-write buffer that are not accessible by the host controller.

The read access time of the prefetch register is faster than the one of the data buffer. The prefetch register allows data to be read from the data buffer at an increased speed by preloading data into the prefetch register.

The entry point of the data buffer, the prefetch buffer, and the post-write buffer is the 32-bit register SD_DATA. A write access to the SD_DATA register followed by a read access from the SD_DATA register corresponds to a write access to the post-write buffer followed by a read access to the prefetch buffer. As a consequence, it is normal that the data of the write access to the SD_DATA register and the data of the read access to the SD_DATA register are different.

The number of 32-bit accesses to the SD_DATA register that are needed to read (or write) a data block with a size of SD_BLK[10:0] BLEN, and equals the rounded up result of BLEN divided by 4. The maximum block size supported by the host controller is hard-coded in the register SD_CAPA[17:16] MBL field and cannot be changed.

A read access to the SD_DATA register is allowed only when the buffer read enable status is set to 1 (SD_PSTATE[11] BRE); otherwise, a bad access (SD_STAT[29] BADA) is signaled.

A write access to the SD_DATA register is allowed only when the buffer write enable status is set to 1 (SD_PSTATE[10] BWE); otherwise, a bad access (SD_STAT[29] BADA) is signaled and the data is not written.

The data buffer has two modes of operation to store and read of the first and second portions of the data buffer:

- When the size of the data block to transfer is less than or equal to MEM_SIZE/2 (in double buffering), two data transfers can occur from one data bus to the other data bus and vice versa at the same time. The MMC/SD/SDIO controller uses the two portions of the data buffer in a ping-pong manner so that storing and reading of the first and second portions of the data buffer are automatically interchanged from time to time so that data may be read from one portion (for instance, through a DMA read access on the interconnect bus) while data (for instance, from the card) is being stored into the other portion and vice versa. When BLEN is less than or equal to 200h (that is, less or equal to 512Bytes), each of the two portions of the buffer that can be used have a size of BLEN (that is, 32-bits x BLEN div by 4). Not more than this total size of 2 times 32-bits × BLEN div by 4 can be used.
- When the size of the data block to transfer is larger than MEM_SIZE/2, only one data transfer can occur from one data bus to the other data bus at a time. The MMC/SD/SDIO host controller uses the entire data buffer as a single portion. In this mode, a bad access (SD_STAT[29] BADA) is signaled when two data transfers occur from one data bus to the other data bus and vice versa at the same time.

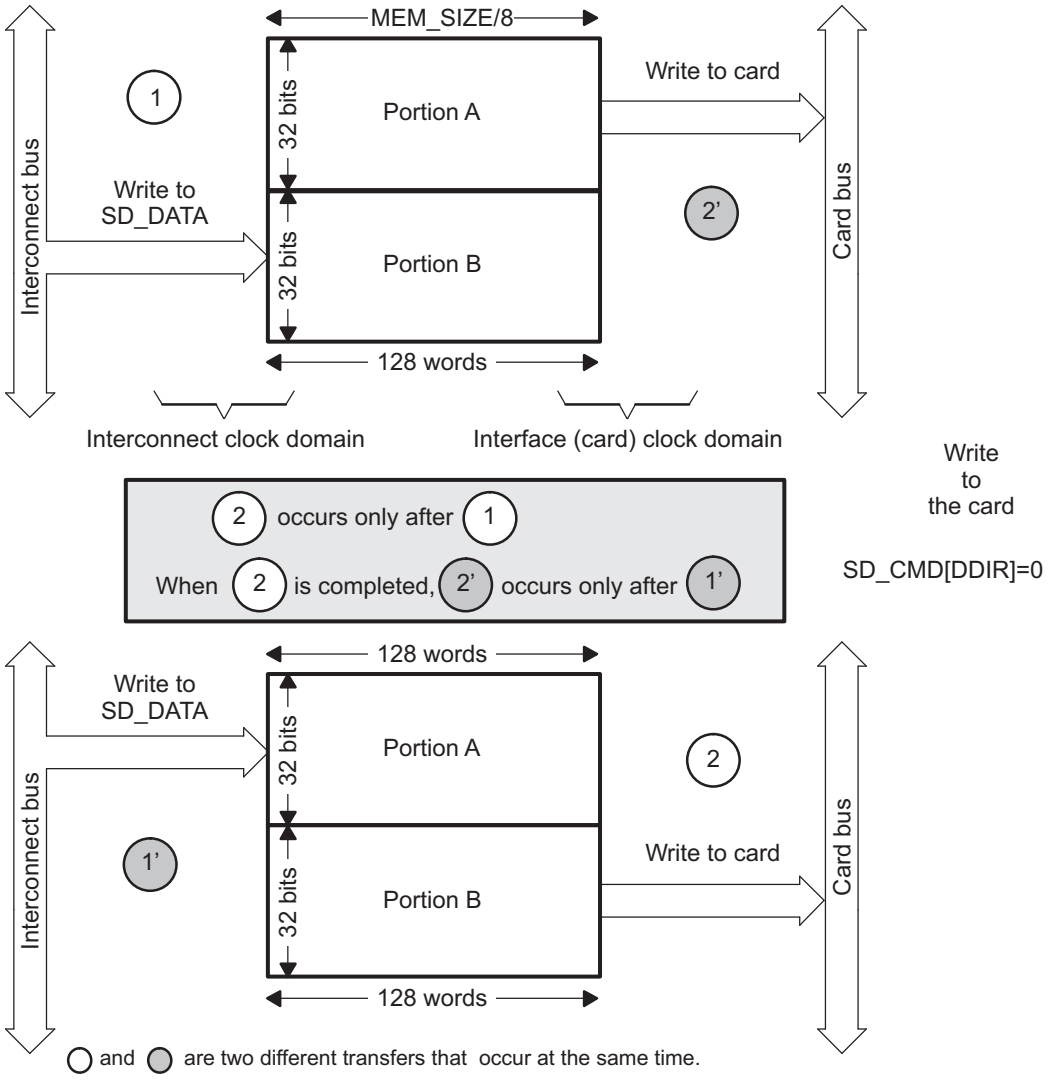
Copyright © 2011, Texas Instruments Incorporated

CAUTION

The SD_CMD[4] DDIR bit must be configured before a transfer to indicate the direction of the transfer.

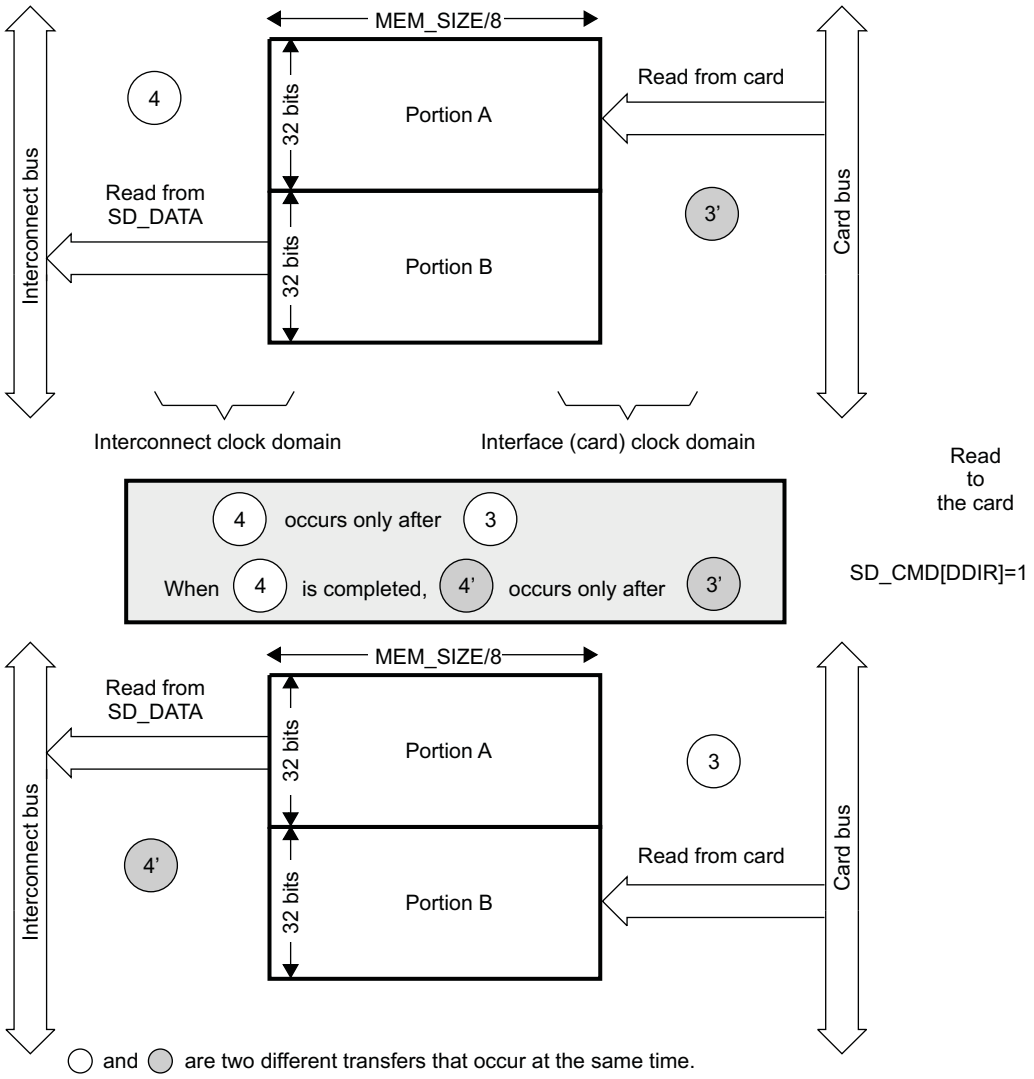
Figure 18-19 shows the buffer management for writing and Figure 18-20 shows the buffer management for reading.

Figure 18-19. Buffer Management for a Write



Copyright © 2011, Texas Instruments Incorporated

Figure 18-20. Buffer Management for a Read



18.3.7.1.1 Memory Size, Block Length, and Buffer Management Relationship

The maximum block length and buffer management that can be targeted by system depend on memory depth setting.

Table 18-12. Memory Size, BLEN, and Buffer Relationship

Memory Size([5:2] MEMSIZE in bytes)	512	1024	2048	4096
Maximum block length supported	512	1024	2048	2048
Double-buffering for maximum block length	N/A	BLEN <= 512	BLEN <= 1024	BLEN <= 2048
Single-buffering for block length	BLEN<=512	512 < BLEN <= 1024	1024 < BLEN <= 2048	N/A

Copyright © 2011, Texas Instruments Incorporated

18.3.7.1.2 Data Buffer Status

The data buffer status is defined in the following interrupt status register and status register:

- Interrupt status registers (see Figure 18-55):
  - SD_STAT[29] BADABad access to data space
  - SD_STAT[5] BRRBuffer read ready
  - SD_STAT[4] BWRBuffer write ready
- Status registers (see Figure 18-52):
  - SD_PSTATE[11] BREBuffer read enable
  - SD_PSTATE[10] BWEBuffer write enable

18.3.8 Transfer Process

The process of a transfer is dependent on the type of command. It can be with or without a response, with or without data.

18.3.8.1 Different Types of Commands

Different types of commands are specific to MMC, SD, or SDIO cards. See the *Multimedia Card System Specification*, the *SD Memory Card Specifications*, the *SDIO Card Specification, Part E1*, or the *SD Card Specification, Part A2, SD Host Controller Standard Specification* for more details.

18.3.8.2 Different Types of Responses

Different types of responses are specific to MMC, SD, or SDIO cards. See the *Multimedia Card System Specification*, the *SD Memory Card Specifications*, the *SDIO Card Specification, Part E1*, or the *SD Card Specification, Part A2, SD Host Controller Standard Specification* for more details.

Table 18-13 shows how the MMC, SD, and SDIO responses are stored in the SD_RSPxx registers.

Table 18-13. MMC, SD, SDIO Responses in the SD_RSPxx Registers

Kind of Response	Response Field	Response Register
R1, R1b (normal response), R3, R4, R5, R5b, R6, R7	RESP[39:8][(1)]	SD_RSP10[31:0]
R1b (Auto CMD12 response)	RESP[39:8][(1)]	SD_RSP76[31:0]
R2	RESP[127:0][(1)]	SD_RSP76[31:0] SD_RSP54[31:0] SD_RSP32[31:0] SD_RSP10[31:0]

(1) RESP refers to the command response format described in the specifications mentioned above.

When the host controller modifies part of the SD_RSPxx registers, it preserves the unmodified bits.

The host controller stores the Auto CMD12 response in the SD_RSP76[31:0] register because the Host Controller may have a multiple block data DAT line transfer executing concurrently with a command. This allows the host controller to avoid overwriting the Auto CMD12 response with the command response stored in SD_RSP10 register and vice versa.

Copyright © 2011, Texas Instruments Incorporated

18.3.9 Transfer or Command Status and Error Reporting

Flags in the MMC/SD/SDIO host controller show status of communication with the card:

- A timeout (of a command, a data, or a response)
- A CRC

Error conditions generate interrupts. See Table 18-14 and register description for more details.

Table 18-14. CC and TC Values Upon Error Detected

Error hold in the SD_STAT Register		CC	TC	Comments
29	BADA			No dependency with CC or TC. BADA is related to the register accesses. Its assertion is not dependent of the ongoing transfer.
28	CERR	1		CC is set upon CERR.
22	DEB		1	TC is set upon DEB.
21	DCRC		1	TC is set upon DCRC.
20	DTO			DTO and TC are mutually exclusive. DCRC and DEB cannot occur with DTO.
19	CIE	1		CC is set upon CIE.
18	CEB	1		CC is set upon CEB.
17	CCRC	1		CC can be set upon CCRC - See CTO comment
16	CTO			CTO and CC are mutually exclusive. CIE, CEB and CERR cannot occur with CTO. CTO can occur at the same time as CCRCit indicates a command abort due to a contention on CMD line. In this case no CC appears.

SD_STAT[21] DCRC event can be asserted in the following conditions:

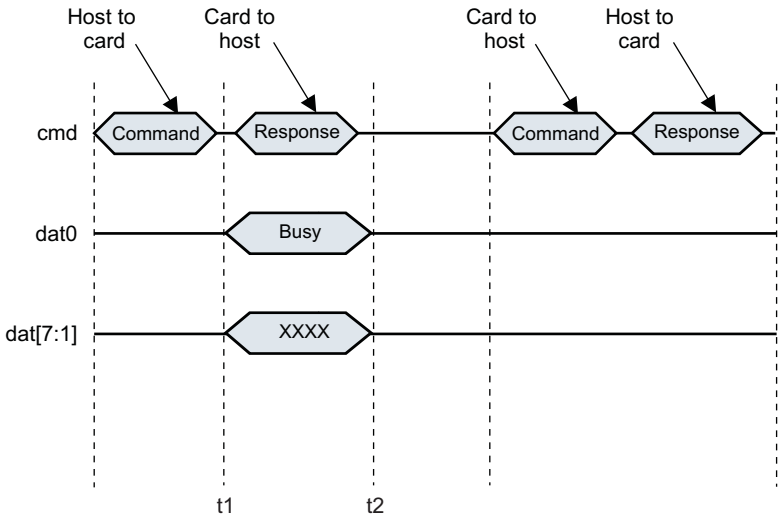
- Busy timeout for R1b, R5b response type
- Busy timeout after write CRC status
- Write CRC status timeout
- Read data timeout
- Boot acknowledge timeout

Copyright © 2011, Texas Instruments Incorporated

18.3.9.1 Busy Timeout for R1b, R5b Response Type

Figure 18-21 shows DCRD event condition asserted when there is a busy timeout for R1b or R5b responses.

Figure 18-21. Busy Timeout for R1b, R5b Responses



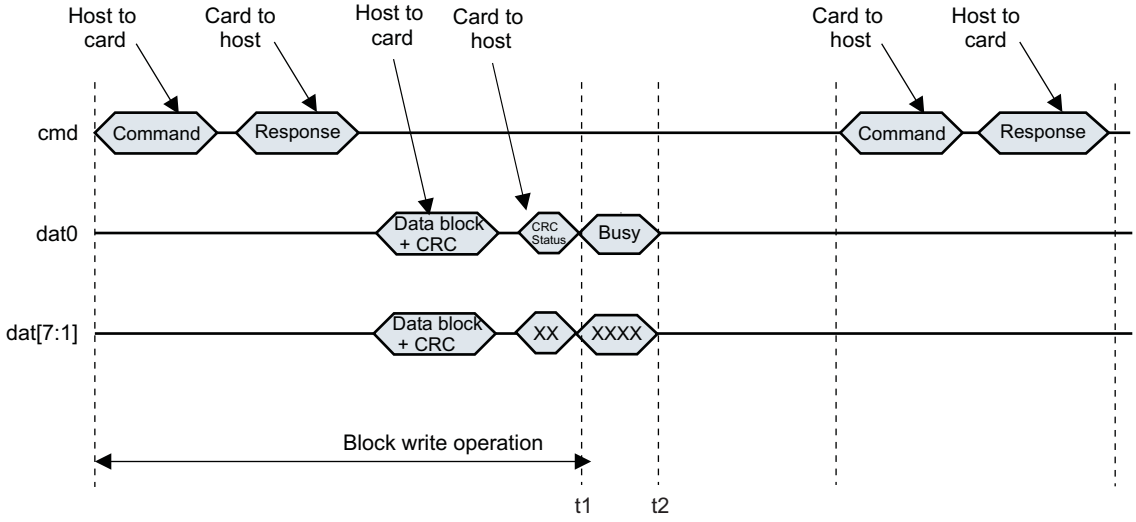
t1 - Data timeout counter is loaded and starts after R1b, R5b response type.

t2 - Data timeout counter stops and if it is 0, SD_STAT[21] DCRC is generated.

18.3.9.2 Busy Timeout After Write CRC Status

Figure 18-22 shows DCRC event condition asserted when there is busy timeout after write CRC status.

Figure 18-22. Busy Timeout After Write CRC Status



t1 - Data timeout counter is loaded and starts after CRC status.

t2 - Data timeout counter stops and if it is 0, SD_STAT[21] DCRC is generated.

18.3.10 Auto Command 12 Timings

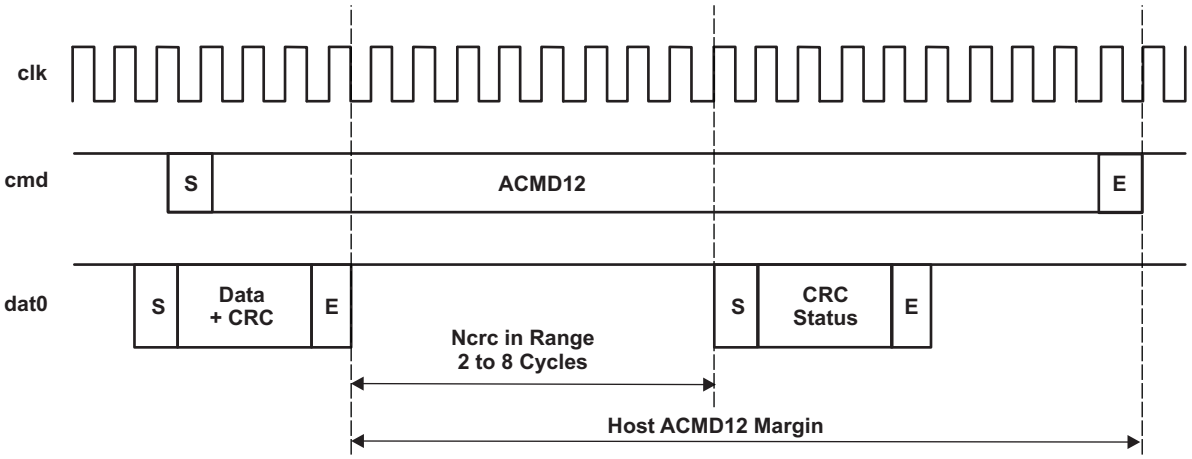
With the UHS definition of SD cards with higher frequency for MMC clocks up to 208, SD standard imposes a specific timing for Auto CMD12 "end bit" arrival.

18.3.10.1 Auto Command 12 Timings During Write Transfer

A margin named Ncrc in range of 2 to 8 cycles has been defined for SDR50 and SDR104 card components for write data transfers, as auto command 12 'end bit' shall arrive after the CRC status "end bit".

Figure 18-27 shows auto CMD12 timings during write transfer.

Figure 18-27. Auto CMD12 Timing During Write Transfer



The Host controller has a margin of 18 clock cycles to make sure that auto CMD12 'end bit' arrives after the CRC status. This margin does not depend on MMC bus configuration, DDR or standard transfer, 1,4 or 8 bus width.

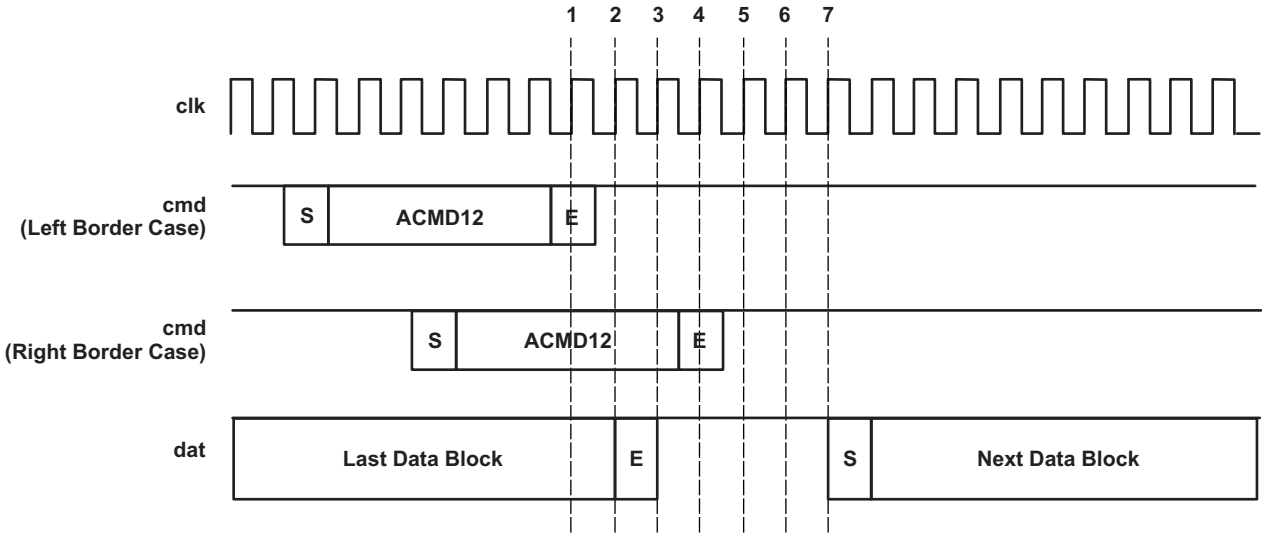
Copyright © 2011, Texas Instruments Incorporated

18.3.10.2 Auto Command 12 Timings During Read Transfer

With UHS very high speed cards gap timing between 2 successive cards has been extended to 4 cycles instead of 2. By the way it gives more flexibility for Host Auto CMD12 arrival in order to receive the last complete and reliable block. SD controller only follows the 'Left Border Case' defined by SD UHS specification.

Figure 18-28 shows ACMD12 timings during read transfer.

Figure 18-28. Auto Command 12 Timings During Read Transfer



The Auto CMD12 arrival sent by the Host controller is not sensitive to the MMC bus configuration whether it is DDR or standard transfer and whether it is a 1,4 or 8 bit bus width transfer.

Copyright © 2011, Texas Instruments Incorporated

18.3.11 Transfer Stop

Whenever a transfer is initiated, the transmission may be willed to stop whereas it is still not finished. Several cases can be faced depending on the transfer type:

- Multiple blocks oriented transfers (for which transfer length is known)
- Continuous stream transfers (which have an infinite length)

NOTE: Since the MMC/SD/SDIO controller manages transfers based on a block granularity, the buffer will accept a block only if there is enough space to completely store it. Consequently, if a block is pending in the buffer, no command will be sent to the card because the card clock will be shut off by the controller.

The MMC/SD/SDIO controller includes two features which make a transfer stop more convenient and easier to manage:

- Auto CMD12 (for MMC and SD only).

  This feature is enabled by setting the SD_CMD[2] ACEN bit to 1 (this setting is relevant for a MMC/SD transfer with a known number of blocks to transfer). When the Auto CMD12 feature is enabled, the MMC/SD/SDIO controller will automatically issue a CMD12 command when the expected number of blocks has been exchanged.

- Stop at block gap

  This feature is enabled by setting the SD_HCTL[16] SBGR bit to 1. When enabled, this capability holds the transfer on until the end of a block boundary. If a stop transmission is needed, software can use this pause to send a CMD12 to the card.

Table 18-15 shows the common ways to stop a transfer, indicating command to send and features to enable.

Table 18-15. MMC/SD/SDIO Controller Transfer Stop Command Summary

		WRITE Transfer		READ Transfer	
		MMC/SD	SDIO	MMC/SD	SDIO
Single block		Transfer ends automatically Wait TC	Transfer ends automatically Wait TC	Transfer ends automatically Wait TC	Transfer ends automatically Wait TC
Multi blocks (finite or infinite)	Before the programmed block boundary	Send CMD12 Wait TC	Send CMD52 Wait TC	Send CMD12 Wait TC	Send CMD52 Wait TC
	Stop at the end of the transfer (finite transfer only)	Auto CMD12 active Transfer ends automatically Wait TC	Set SD_HCTL[16] SBGR bit to 1. Send CMD52 Wait TC	Auto CMD12 active Transfer ends automatically Wait TC	**If READ_WAIT supported** Stop at block gap Wait TC
					If READ_WAIT not supported Send CMD52 Wait TC

NOTE: The MMC/SD/SDIO controller will send the stop command to the card on a block boundary, regardless the moment the command was written to the controller registers.

18.3.12 Output Signals Generation

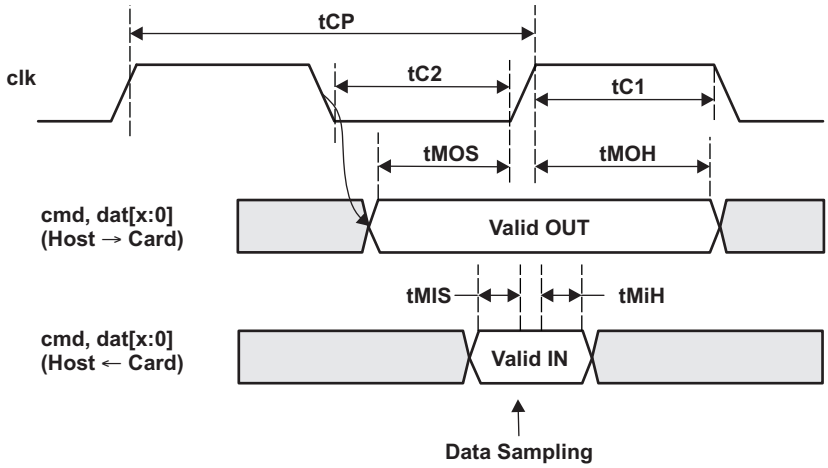
The MMC/SD/SDIO output signals can be driven on either falling edge or rising edge depending on the SD_HCTL[2] HSPE bit. This feature allows to reach better timing performance, and thus to increase data transfer frequency.

18.3.12.1 Generation on Falling Edge of MMC Clock

The controller is by default in this mode to maximize hold timings. In this case, SD_HCTL[2] HSPE bit is cleared to 0.

Figure 18-29 shows the output signals of the module when generating from the falling edge of the MMC clock.

Figure 18-29. Output Driven on Falling Edge



18.3.12.2 Generation on Rising Edge of MMC Clock

This mode increases setup timings and allows reaching higher bus frequency. This feature is activated by setting SD_HCTL[2] HSPE bit to 1. The controller shall be set in this mode to support SDR transfers.

NOTE: Do not use this feature in Dual Data Rate mode (when SD_CON[19] DDR is set to 1).

Figure 18-30 shows the output signals of the module when generating from the rising edge of the MMC clock.

18.3.13 Card Boot Mode Management

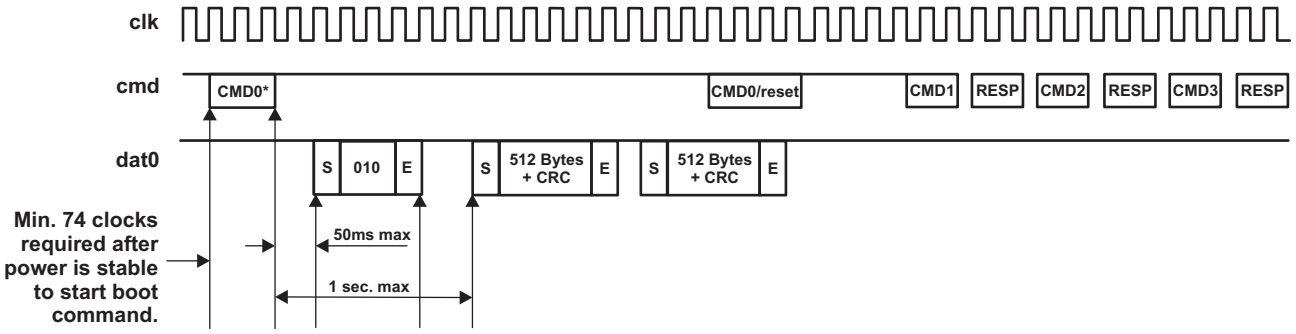
Boot Operation Mode allows the MMC/SD/SDIO host controller to read boot data from the connected slave (MMC device) by keeping CMD line low after power-on (or sending CMD0 with specific argument) before issuing CMD1. The data can be read from either boot area or user area, depending on register setting. Power-on boot defines a way for the boot-code to be accessed by the MMC/SD/SDIO host controller without an upper-level software driver, speeding the time it takes for a controller to access the boot code.

The two possible ways to issue a boot command (either issuing a CMD0 or driving the CMD line to 0 during the whole boot phase) are described in the following sections.

18.3.13.1 Boot Mode Using CMD0

Figure 18-31 shows the timing diagram of a boot sequence using CMD0.

Figure 18-31. Boot Mode With CMD0

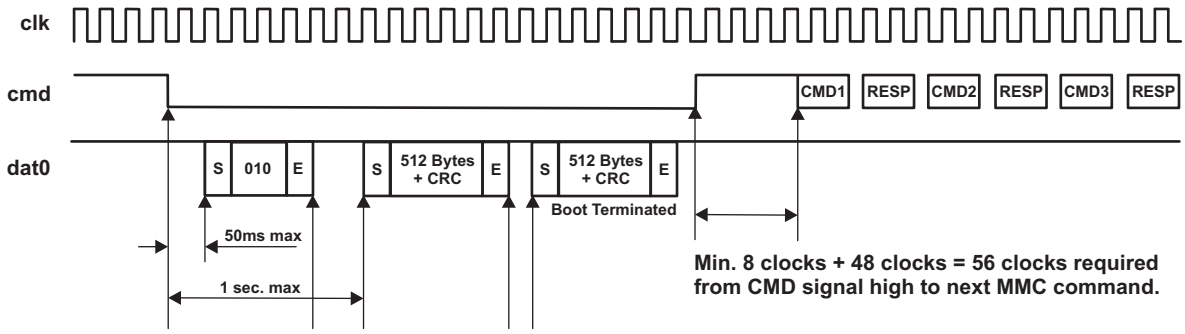


* Refer to MMC Specification for correct argument.

18.3.13.2 Boot Mode With CMD Held Low

Figure 18-32 shows the timing diagram of a boot sequence with CMD line tied to 0.

Figure 18-32. Boot Mode With CMD Line Tied to 0



For more information on how to configure the MMC/SD/SDIO host controller, see the section titled Boot with CMD line tied to 0.

18.3.14 CE-ATA Command Completion Disable Management

The MMC/SD/SDIO controller supports CE-ATA features, in particular the detection of command completion token. When a command that requires a command completion signal (SD_CON[12] CEATA and SD_CMD[2] ACEN set to 1) is launched, the host system is no longer allowed to emit a new command in parallel of data transfer unless it is a command completion disable token.

The settings to emit a command completion disable token follow:

- SD_CON[12] CEATA is set to 1.
- SD_CON[2] HR set to 1.
- Clear the SD_ARG register.
- Write into SD_CMD register with value 0000 0000h.

When a command completion disable token was emitted (that is, SD_STAT[0] CC received), the host system is again allowed to emit another type of command (for example a transfer abort command CMD12 to abort transfer).

A critical case can be met when command completion signal disable (CCSD) is emitted during the last data block transfer, the sequence on command line could be sent very close to command completion signal (CCS) token sent by the card.

Three cases can be met:

- CCS is receive just before CCSD is emitted:

  An interrupt CIRQ is generated with CCS detection, CCSD is transmitted to card then an interrupt CC is generated when CCSD ends. In this case, card consider the CCSD sequence.
- CCS is not generated or generated during the CCSD transfer:

  The CCS bit cannot be detected (conflict is not possible as they drive the same level on command line, then no CIRQ interrupt is generated; besides CC interrupt is generated when CCSD ends).
- CCS is generated without CCSD token required:

  Only the interrupt CIRQ is generated when CCS is detected.

18.3.15 Test Registers

Test registers are available to be compliant with SD Host controller specification. This feature is useful to generate interrupts manually for driver debugging. The Force Event register (SD_FE) is used to control the Error Interrupt Status and Auto CMD12 Error Status. The System Test register (SD_SYSTEST) is used to control the signals that connect to I/O pins when the module is configured in system test (SD_CON[4] MODE = 1) mode for boundary connectivity verification.

18.3.16 MMC/SD/SDIO Hardware Status Features

Table 18-16 summarizes the MMC/SD/SDIO hardware status features.

Table 18-16. MMC/SD/SDIO Hardware Status Features

Feature	Type	Register/Bit Field/Observability Control	Description
Interrupt flags		See Section 18.3.4.	
CMD line signal level	Status	[24] CLEV	Indicates the level of the cmd line
DAT lines signal level	Status	[23:20] DLEV	Indicates the level of the data lines
Buffer read enable	Status	[11] BRE	Readable data exists in the buffer.
Buffer write enable	Status	[10] BWE	Indicates whether there is enough space in the buffer to write BLEN bytes of data
Read transfer active	Status	[9] RTA	This status is used for detecting completion of a read transfer.
Write transfer active	Status	[8] WTA	This status indicates a write transfer active.
Data line active	Status	[2] DLA	Indicates whether the data lines are active
Command Inhibit (data lines)	Status	[1] DATI	Indicates whether issuing of command using data lines is allowed
Command inhibit (CMD line)	Status	[0] CMDI	Indicates whether issuing of command using CMD line is allowed

18.3.17 Low-Level Programming Models

18.3.17.1 Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the module has to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the MMC/SD/SDIO modules.

Table 18-17. Global Init for Surrounding Modules

Surrounding Modules	Comments
PRCM	Module interface and functional clocks must be enabled. For more information, see Power, Reset, and Clock Management (PRCM) chapter
Control module	Module-specific pad muxing and configuration must be set in the control module. See Control Module chapter.
(optional) MPU INTC	MPU INTC configuration must be done to enable the interrupts from the SD module. See Interrupt Controller chapter
(optional) sDMA (or dDMA)	DMA configuration must be done to enable the module DMA channel requests. See SDMA chapter
(optional) Interconnect	For more information about the interconnect configuration, see Interconnect chapter

NOTE: The MPU interrupt controller and the sDMA/dDMA configurations are necessary, if the interrupt and DMA based communication modes are used.

18.3.17.2 MMC/SD/SDIO Controller Initialization Flow

The next sections outline the four steps to initialize the MMC/SD/SDIO controller:

- Initialize Clocks
- Software reset of the controller
- Set module's hardware capabilities
- Set module's Idle and Wake-Up modes

18.3.17.2.1 Enable OCP and CLKADPI Clocks

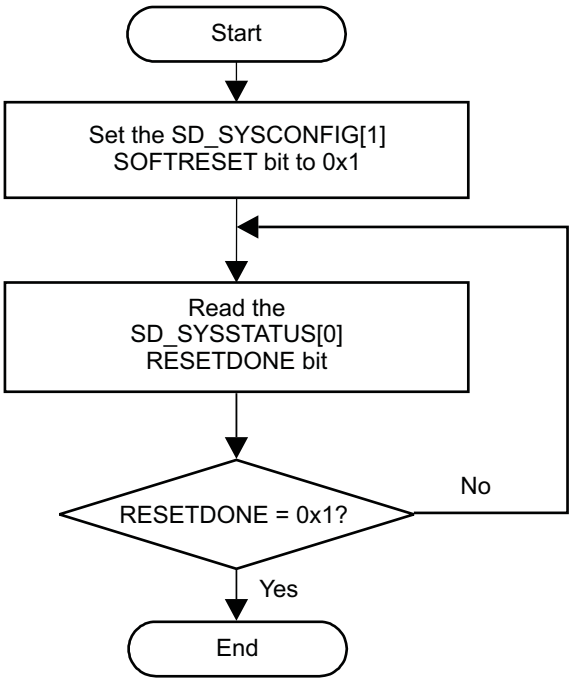
Prior to any SD register access one must enable the SD OCP clock and CLKADPI clock in PRCM module registers. Refer to the *Power, Reset, and Clock Management* chapter.

Copyright © 2011, Texas Instruments Incorporated

18.3.17.2.2 SD Soft Reset Flow

Figure 18-33 shows the soft reset process of MMC/SD/SDIO controller.

Figure 18-33. MMC/SD/SDIO Controller Software Reset Flow



18.3.17.2.3 Set SD Default Capabilities

Software must read capabilities (in boot ROM for instance) and is allowed to set (write) SD_CAPA[26:24] and SD_CUR_CAPA[23:0] registers before the MMC/SD/SDIO host driver is started.

18.3.17.2.4 Wake-Up Configuration

Table 18-18 details SD controller wake-up configuration.

Table 18-18. MMC/SD/SDIO Controller Wake-Up Configuration

Step	Access Type	Register/Bit Field/Programming Model
Configure wake-up bit (if necessary).	W	SD_SYSCONFIG[2] ENAWAKEUP
Enable wake-up events on SD card interrupt (if necessary).	W	SD_HCTL[24] IWE
SDIO Card onlyEnable card interrupt (if necessary).	W	SD_IE[8] CIRQENABLE

18.3.17.3 Operational Modes Configuration

18.3.17.3.1 Basic Operations for MMC/SD/SDIO Host Controller

The MMC/SD/SDIO controller performs data transfers: data to card (referred to as write transfers) and data from card (referred to as read transfers).

The host controller requires transfers to run on a block-by-block basis, rather than on a DMA burst size basis. A single DMA request (or block request interrupt) is signaled for each block. Pipelining is supported as long as the block size is less than one half of the memory buffer size.

18.3.17.3.2 Card Detection, Identification, and Selection

Figure 18-35 and Figure 18-36 show the card identification and selection process.

Figure 18-35. MMC/SD/SDIO Controller Card Identification and Selection - Part 1

18.4 MMC/SD/SDIO Registers

Table 18-19 lists the MMC/SD/SDIO registers.

CAUTION

The MMC/SD/SDIO registers are limited to 32-bit data accesses. 16-bit and 8-bit are not allowed and can corrupt register content.

Table 18-19. MMC/SD/SDIO Registers

18.4.1 System Configuration Register (SD_SYSCONFIG)

This register allows controlling various parameters of the OCP interface. The system configuration register (SD_SYSCONFIG) is shown in Figure 18-37 and described in Table 18-20.

Figure 18-37. System Configuration Register (SD_SYSCONFIG)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
R-0															

15	14	13	12	11	10	9	8
Reserved		STANDBYMODE		Reserved		CLOCKACTIVITY	
R-0		R/W-2h		R-0		R/W-0	

7	6	5	4	3	2	1	0
Reserved			SIDLEMODE		ENAWAKEUP	SOFTRESET	AUTOIDLE
R-0			R/W-2h		R/W-1	R/W-0	R/W-1

LEGENDR/W = Read/Write; R = Read only; *-n* = value after reset

Table 18-20. System Configuration Register (SD_SYSCONFIG) Field Descriptions

Bit	Field	Value	Description
31-14	Reserved	0	These bits are initialized to zero, and writes to them are ignored. Reads return 0.
13-12	STANDBYMODE		Master interface power Management, standby/wait control. The bit field is only useful when generic parameter MADMA_EN (Master ADMA enable) is set as active, otherwise it is a read only register read a 0.
		0	Force-standby. Mstandby is forced unconditionally.
		1h	No-standby. Mstandby is never asserted.
		2h	Smart-standby modelocal initiator standby status depends on local conditions, i.e. the module's functional requirement from the initiator. IP module shall not generate (initiator-related) wake-up events.
		3h	Smart-Standby wake-up-capable modelocal initiator standby status depends on local conditions, i.e. the module's functional requirement from the initiator. IP module can generate (master-related) wake-up events when in standby state. Mode is only relevant if the appropriate IP module "mwake-up" output is implemented. Functional clock is maintained. Interface clock may be switched off.
11-10	Reserved	0	These bits are initialized to zero, and writes to them are ignored. Reads return 0.
9-8	CLOCKACTIVITY		Clocks activity during wake up mode period.
		Bit 8	Interface clock
		Bit 9	Functional clock
		0	Interface and Functional clock may be switched off.
		1h	Interface clock is maintained. Functional clock may be switched-off.
		2h	Functional clock is maintained. Interface clock may be switched-off.
		3h	Interface and Functional clocks are maintained.
7-5	Reserved	0	These bits are initialized to zero, and writes to them are ignored. Reads return 0.
4-3	SIDLEMODE		Power management
		0	If an idle request is detected, the MMC/SD/SDIO host controller acknowledges it unconditionally and goes in Inactive mode. Interrupt and DMA requests are unconditionally deasserted.
		1h	If an idle request is detected, the request is ignored and the module keeps on behaving normally.
		2h	If an idle request is detected, the module will switch to wake up mode based on its internal activity, and the wake up capability can be used if the wake up capability is enabled (bit SD_SYSCONFIG[2] ENAWAKEUP bit is set to 1).
		3h	Smart-idle Wake-up capable modelocal target's idle state eventually acknowledges the system's idle requests, depending on the IP modules internal requirements. IP module may generate (IRQ- or DMA-request-related) wake-up events when in idle state. Mode is only relevant if the appropriate IP module "swake-up" output(s) is (are) implemented.

Copyright © 2011, Texas Instruments Incorporated

Table 18-20. System Configuration Register (SD_SYSCONFIG) Field Descriptions (continued)

Bit	Field	Value	Description
2	ENAWAKEUP		Wake-up feature control
		0	Wake-up capability is disabled.
		1	Wake-up capability is enabled.
1	SOFTRESET		Software reset. The bit is automatically reset by the hardware. During reset, it always returns 0.
		Read 0	Normal mode
		Write 0	No effect
		Read 1	The module is reset.
		Write 1	Trigger a module reset.
0	AUTOIDLE		Internal Clock gating strategy
		Read 0	Clocks are free-running.
		Write 1	Automatic clock gating strategy is applied, based on the interconnect and MMC interface activity.

18.4.2 System Status Register (SD_SYSSTATUS)

This register provides status information about the module excluding the interrupt status information. The system status register (SD_SYSSTATUS) is shown in Figure 18-38 and described in Table 18-21.

Figure 18-38. System Status Register (SD_SYSSTATUS)

31	1	0
Reserved		RESETDONE
R-0		R-0

LEGENDR/W = Read/Write; R = Read only; -*n* = value after reset

Table 18-21. System Status Register (SD_SYSSTATUS) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved bit field. Do not write any value.
0	RESETDONE		Internal Reset Monitoring. Notethe debounce clock , the interface clock and the functional clock shall be provided to the MMC/SD/SDIO host controller to allow the internal reset monitoring.
		Read 0	Internal module reset is on-going
		Read 1	Reset completed

18.4.3 Card Status Response Error (SD_CSRE)

This register enables the host controller to detect card status errors of response type R1, R1b for all cards and of R5, R5b and R6 response for cards types SD or SDIO. When a bit SD_CSRE[i] is set to 1, if the corresponding bit at the same position in the response SD_RSP10[I] is set to 1, the host controller indicates a card error (SD_STAT[28] CERR bit) interrupt status to avoid the host driver reading the response register (SD_RSP10).

NOTE: No automatic card error detection for autoCMD12 is implemented; the host system has to check autoCMD12 response register (SD_RSP76) for possible card errors.

The card status response error (SD_CSRE) is shown in Figure 18-39 and described in Table 18-22.

Figure 18-39. Card Status Response Error (SD_CSRE)

31	0
CSRE	
R/W-0

18.4.4 System Test Register (SD_SYSTEST)

This register is used to control the signals that connect to I/O pins when the module is configured in system test (SYSTEST) mode for boundary connectivity verification.

NOTE: In SYSTEST mode, a write into SD_CMD register will not start a transfer. The buffer behaves as a stack accessible only by the local host (push and pop operations). In this mode, the Transfer Block Size (SD_BLK[10:0] BLEN bits) and the Blocks count for current transfer (SD_BLK[31:16] NBLK bits) are needed to generate a Buffer write ready interrupt (SD_STAT[4] BWR bit) or a Buffer read ready interrupt (SD_STAT[5] BRR bit) and DMA requests if enabled.

The system test register (SD_SYSTEST) is shown in Figure 18-40 and described in Table 18-23.

Figure 18-40. System Test Register (SD_SYSTEST)

31						17	16
Reserved							OBI

R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0

LEGENDR/W = Read/Write; R = Read only; *-n* = value after reset

Table 18-23. System Test Register (SD_SYSTEST) Field Descriptions

Bit	Field	Value	Description
31-17	Reserved	0	Reserved bit field. Do not write any value. Reads return 0.
16	OBI		Out-of-band interrupt (OBI) data value.
		0	The out-of-band interrupt pin is driven low.
		1	The out-of-band interrupt pin is driven high.
15	SDCD		Card detect input signal (SDCD) data value
		0	The card detect pin is driven low.
		1	The card detect pin is driven high.
14	SDWP		Write protect input signal (SDWP) data value
		0	The write protect pin SDWP is driven low.
		1	he write protect pin SDWP is driven high.
13	WAKD		Wake request output signal data value
		Read 0	No action. Returns 0.
		Write 0	The pin SWAKEUP is driven low.
		Read 1	No action. Returns 1.
		Write 1	The pin SWAKEUP is driven high.
12	SSB		Set status bit. This bit must be cleared prior attempting to clear a status bit of the interrupt status register (SD_STAT).
		Read 0	No action. Returns 0.
		Write 0	Clear this SSB bit field. Writing 0 does not clear already set status bits.
		Read 1	No action. Returns 1.
		Write 1	Force to 1 all status bits of the interrupt status register (SD_STAT) only if the corresponding bit field in the Interrupt signal enable register (SD_ISE) is set.

Table 18-23. System Test Register (SD_SYSTEST) Field Descriptions (continued)

Bit	Field	Value	Description
11	D7D		DAT7 input/output signal data value
		Read 0	If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT7 line (low). If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 0.
		Write 0	If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT7 line is driven low. If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect.
		Read 1	If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT7 line (high) If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 1.
		Write 1	If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT7 line is driven high. If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect.
10	D6D		DAT6 input/output signal data value
		Read 0	If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT6 line (low). If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 0.
		Write 0	If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT6 line is driven low. If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect.
		Read 1	If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT6 line (high) If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 1.
		Write 1	If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT6 line is driven high. If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect.
9	D5D		DAT5 input/output signal data value
		Read 0	If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT5 line (low). If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 0.
		Write 0	If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT5 line is driven low. If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect.
		Read 1	If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT5 line (high) If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 1.
		Write 1	If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT5 line is driven high. If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect.
8	D4D		DAT4 input/output signal data value
		Read 0	If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT4 line (low). If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 0.
		Write 0	If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT4 line is driven low. If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect.
		Read 1	If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT4 line (high) If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 1.
		Write 1	If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT4 line is driven high. If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect.
7	D3D		DAT3 input/output signal data value
		Read 0	If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT3 line (low). If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 0.
		Write 0	If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT3 line is driven low. If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect.
		Read 1	If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT3 line (high) If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 1.
		Write 1	If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT3 line is driven high. If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect.
6	D2D		DAT2 input/output signal data value
		Read 0	If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT2 line (low). If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 0.
		Write 0	If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT2 line is driven low. If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect.
		Read 1	If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT2 line (high) If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 1.
		Write 1	If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT2 line is driven high. If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect.

Table 18-23. System Test Register (SD_SYSTEST) Field Descriptions (continued)

Bit	Field	Value	Description
5	D1D		DAT1 input/output signal data value
		Read 0	If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT1 line (low). If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 0.
		Write 0	If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT1 line is driven low. If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect.
		Read 1	If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT1 line (high) If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 1.
		Write 1	If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT1 line is driven high. If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect.
4	D0D		DAT0 input/output signal data value
		Read 0	If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT0 line (low). If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 0.
		Write 0	If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT0 line is driven low. If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect.
		Read 1	If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT0 line (high) If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 1.
		Write 1	If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT0 line is driven high. If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect.
3	DDIR		Control of the DAT[7:0] pins direction
		Read 0	No action. Returns 0.
		Write 0	The DAT lines are outputs (host to card).
		Read 1	No action. Returns 1.
		Write 1	The DAT lines are inputs (card to host).
2	CDAT		CMD input/output signal data value
		Read 0	If SD_SYSTEST[1] CDIR bit = 1 (input mode direction), returns the value on the CMD line (low). If SD_SYSTEST[1] CDIR bit = 0 (output mode direction), returns 0 .
		Write 0	If SD_SYSTEST[1] CDIR bit = 0 (output mode direction), the CMD line is driven low. If SD_SYSTEST[1] CDIR bit = 1 (input mode direction), no effect.
		Read 1	If SD_SYSTEST[1] CDIR bit = 1 (input mode direction), returns the value on the CMD line (high) If SD_SYSTEST[1] CDIR bit = 0 (output mode direction), returns 1 .
		Write 1	If SD_SYSTEST[1] CDIR bit = 0 (output mode direction), the CMD line is driven high. If SD_SYSTEST[1] CDIR bit = 1 (input mode direction), no effect.
1	CDIR		Control of the CMD pin direction
		Read 0	No action. Returns 0.
		Write 0	The CMD line is an output (host to card).
		Read 1	No action. Returns 1.
		Write 1	The CMD line is an input (card to host) .
0	MCKD		MMC clock output signal data value
		Read 0	No action. Returns 0.
		Write 0	The output clock is driven low.
		Read 1	No action. Returns 1.
		Write 1	The output clock is driven high.

18.4.5 Configuration Register (SD_CON)

This register is used:

- To select the functional mode for any card
- To send an initialization sequence to any card
- To send an initialization sequence to any card
- To enable the detection on the mmc_dat[1] signal of a card interrupt for SDIO cards only

It also configures:

- The parameters related to the card detect and write protect input signals

The configuration register (SD_CON) is shown in Figure 18-41 and described in Table 18-24.

Figure 18-41. Configuration Register (SD_CON)

31	30	29	28	27	26	25	24
Reserved							
R-0

R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0

LEGENDR/W = Read/Write; R = Read only; -*n* = value after reset

Table 18-24. Configuration Register (SD_CON) Field Descriptions

Bit	Field	Value	Description
31-22	Reserved	0	Reserved bit field. Do not write any value.
21	SDMA_LnE		Slave DMA Level/Edge Request. The waveform of the DMA request can be configured either edge sensitive with early de-assertion on first access to SD_DATA register or late de-assertion, request remains active until last allowed data written into SD_DATA.
		0	Slave DMA edge sensitive.
		1	Slave DMA level sensitive.
20	DMA_MnS		DMA Master or Slave selection. When this bit is set and the controller is configured to use the DMA, Ocp master interface is used to get datas from system using ADMA2 procedure (direct access to the memory).
			This option is only available if generic parameter MADMA_EN is asserted to 1.
		0	The controller is slave on data transfers with system.
		1	Not available on this device.
19	DDR		Dual Data Rate mode. When this register is set, the controller uses both clock edge to emit or receive data. Odd bytes are transmitted on falling edges and even bytes are transmitted on rise edges. It only applies on Data bytes and CRC, Start, end bits and CRC status are kept full cycle. This bit field is only meaningful and active for even clock divider ratio of SD_SYSCTL[CLKD], it is insensitive to SD_HCTL[HSPE] setting
		0	Standard modeData are transmitted on a single edge.
		1	Data Bytes and CRC are transmitted on both edges.

Copyright © 2011, Texas Instruments Incorporated

Table 18-24. Configuration Register (SD_CON) Field Descriptions (continued)

Bit	Field	Value	Description
18	BOOT_CF0		Boot Status Supported. This register is set when the CMD line needs to be forced to 0 for a boot sequence. CMD line is driven to 0 after writing in SD_CMD. The line is released when this bit field is de-asserted and aborts data transfer in case of a pending transaction.
		Read 0	CMD line not forced.
		Read 1	CMD line is released when it was previously forced to 0 by a boot sequence.
		Write 0	CMD line forced to 0 is enabled.
		Write 1	CMD line forced to 0 is enabled and will be active after writing into SD_CMD register.
17	BOOT_ACK		Book acknowledge received. When this bit is set the controller should receive a boot status on DAT0 line after next command issued. If no status is received a data timeout will be generated.
		0	No acknowledge to be received.
		1	A boot status will be received on DAT0 line after issuing a command.
16	CLKEXTFREE		External clock free running. This register is used to maintain card clock out of transfer transaction to enable slave module (for example to generate a synchronous interrupt on mmc_dat[1]). The Clock will be maintain only if SD_SYSCTL[2] CEN bit is set.
		0	External card clock is cut off outside active transaction period.
		1	External card clock is maintain even out of active transaction period only if SD_SYSCTL[2] CEN bit is set.
15	PADEN		Control power for MMC lines. This register is only useful when MMC PADs contain power saving mechanism to minimize its leakage power. It works as a GPIO that directly control the ACTIVE pin of PADs. Excepted for mmc_dat[1] , the signal is also combine outside the module with the dedicated power control SD_CON[11] CTPL bit.
		0	ADPIDLE module pin is not forced, it is automatically generated by the MMC fsms.
		1	ADPIDLE module pin is forced to active state
14-13	Reserved	0	Any writes to these bits will result in 0.
12	CEATA		CE-ATA control mode (MMC cards compliant with CE-ATA). This bit selects the active level of the out-of-band interrupt coming from MMC cards. The usage of the Out-of-Band signal (OBI) is not supported.
		0	Standard MMC/SD/SDIO mode.
		1	CE-ATA mode. Next commands are considered as CE-ATA commands.
11	CTPL		Control Power for mmc_dat[1] line (SD cards). By default, this bit is cleared to 0 and the host controller automatically disables all the input buffers outside of a transaction to minimize the leakage current.
			SDIO cards. When this bit is set to 1, the host controller automatically disables all the input buffers except the buffer of mmc_dat[1] outside of a transaction in order to detect asynchronous card interrupt on mmc_dat[1] line and minimize the leakage current of the buffers.
		0	Disable all the input buffers outside of a transaction.
		1	Disable all the input buffers except the buffer of mmc_dat[1] outside of a transaction.
10-9	DVAL		Debounce filter value (all cards). This register is used to define a debounce period to filter the card detect input signal (SDCD). The usage of the card detect input signal (SDCD) is optional and depends on the system integration and the type of the connector housing that accommodates the card.
		0	33 us debounce period
		1h	231 us debounce period
		2h	1 ms debounce period
		3h	8.4 ms debounce period
8	WPP		Write protect polarity (SD and SDIO cards only). This bit selects the active level of the write protect input signal (SDWP). The usage of the write protect input signal (SDWP) is optional and depends on the system integration and the type of the connector housing that accommodates the card.
		0	Active high level
		1	Active low level

Copyright © 2011, Texas Instruments Incorporated

Table 18-24. Configuration Register (SD_CON) Field Descriptions (continued)

Bit	Field	Value	Description
7	CDP		Card detect polarity (all cards). This bit selects the active level of the write protect input signal (SDWP). The usage of the write protect input signal (SDWP) is optional and depends on the system integration and the type of the connector housing that accommodates the card.
		0	Active high level
		1	Active low level
6	MIT		MMC interrupt command (MMC cards only). This bit must be set to 1, when the next write access to the command register (SD_CMD) is for writing a MMC interrupt command (CMD40) requiring the command timeout detection to be disabled for the command response.
		0	Command timeout enabled.
		1	Command timeout disabled.
5	DW8		8-bit mode MMC select (MMC cards only). For SD/SDIO cards, this bit must be cleared to 0. For MMC card, this bit must be set following a valid SWITCH command (CMD6) with the correct value and extend CSD index written in the argument. Prior to this command, the MMC card configuration register (CSD and EXT_CSD) must be verified for compliancy with MMC standard specification.
		0	1-bit or 4-bit data width
		1	8-bit data width
4	MODE		Mode select (all cards). This bit selects the functional mode.
		0	Functional mode. Transfers to the MMC/SD/SDIO cards follow the card protocol. The MMC clock is enabled. MMC/SD transfers are operated under the control of the SD_CMD register.
		1	SYSTEST mode. SYSTEST mode. The signal pins are configured as general-purpose input/output and the 1024-byte buffer is configured as a stack memory accessible only by the local host or system DMA. The pins retain their default type (input, output or in-out). SYSTEST mode is operated under the control of the SYSTEST register.
3	STR		Stream command (MMC cards only). This bit must be set to 1 only for the stream data transfers (read or write) of the adtc commands. Stream read is a class 1 command (CMD11READ_DAT_UNTIL_STOP). Stream write is a class 3 command (CMD20WRITE_DAT_UNTIL_STOP).
		0	Block oriented data transfer
		1	Stream oriented data transfer
2	HR		Broadcast host response (MMC cards only). This register is used to force the host to generate a 48-bit response for bc command type. It can be used to terminate the interrupt mode by generating a CMD40 response by the core. In order to have the host response to be generated in open drain mode, the register SD_CON[OD] must be set to 1. When SD_CON[12] CEATA bit is set to 1 and SD_ARG cleared to 0, when writing 0000 0000h into SD_CMD register, the host controller performs a 'command completion signal disable' token (i.e., mmc_cmd line held to 0 during 47 cycles followed by a 1).
		0	The host does not generate a 48-bit response instead of a command.
		1	The host generates a 48-bit response instead of a command or a command completion signal disable token.
1	INIT		Send initialization stream (all cards). When this bit is set to 1, and the card is idle, an initialization sequence is sent to the card. An initialization sequence consists of setting the mmc_cmd line to 1 during 80 clock cycles. The initialization sequence is mandatory - but it is not required to do it through this bit - this bit makes it easier. Clock divider (SD_SYSCTL[15:6] CLKD bits) should be set to ensure that 80 clock periods are greater than 1ms. Notein this mode, there is no command sent to the card and no response is expected. A command complete interrupt will be generated once the initialization sequence is completed. SD_STAT[0] CC bit can be polled.
		0	The host does not send an initialization sequence
		1	The host sends an initialization sequence
0	OD		Card open drain mode (MMC cards only). This bit must be set to 1 for MMC card commands 1, 2, 3 and 40, and if the MMC card bus is operating in open-drain mode during the response phase to the command sent. Typically, during card identification mode when the card is either in idle, ready or ident state. It is also necessary to set this bit to 1, for a broadcast host response (see Broadcast host response register SD_CON[2] HR bit)
		0	No open drain
		1	Open drain or broadcast host response

18.4.6 Power Counter Register (SD_PWCNT)

This register is used to program a mmc counter to delay command transfers after activating the PAD power, this value depends on PAD characteristics and voltage. The power counter register (SD_PWCNT) is shown in Figure 18-42 and described in Table 18-25.

Figure 18-42. Power Counter Register (SD_PWCNT)

31	16	15	0
Reserved		PWRCNT	
R-0		R/W-0	

LEGENDR/W = Read/Write; R = Read only; -*n* = value after reset

Table 18-25. Power Counter Register (SD_PWCNT) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	These bits are initialized to zero, and writes to them are ignored. Reads return 0.
15-0	PWRCNT		Power counter register. This register is used to introduce a delay between the PAD ACTIVE pin assertion and the command issued.
		0	No additional delay added
		1h	TCF delay (card clock period)
		2h	TCF x 2 delay (card clock period)
		FFFEh	TCF x 65534 delay (card clock period)
		FFFFh	TCF x 65535 delay (card clock period)

18.4.7 SDMA System Address (SD_SDMASA)

This register is used to program a mmc counter to delay command transfers after activating the PAD power. This value depends on PAD characteristics and voltage. The SDMA System address (SD_SDMASA) is shown in Figure 18-39 and described in Table 18-22.

Figure 18-43. Card Status Response Error (SD_SDMASA)

31	0
SDMA_SYSADDR	
R-0	

LEGENDR/W = Read/Write; R = Read only; -*n* = value after reset

Table 18-26. Card Status Response Error (SD_SDMASA) Field Descriptions

Bit	Field	Value	Description
31-0	SDMA_SYSADDR		This register contains the system memory address for a SDMA transfer. When the Host Controller stops a SDMA transfer, this register shall point to the system address of the next contiguous data position. It can be accessed only if no transaction is executing (i.e., after a transaction has stopped). Read operations during transfers may return an invalid value. The Host Driver shall initialize this register before starting a SDMA transaction. After SDMA has stopped, the next system address of the next contiguous data position can be read from this register. The SDMA transfer waits at the every boundary specified by the Host SDMA Buffer Boundary in the Block Size register. The Host Controller generates DMA Interrupt to request the Host Driver to update this register. The Host Driver sets the next system address of the next data position to this register. When the most upper byte of this register (003h) is written, the Host Controller restarts the SDMA transfer. When restarting SDMA by the Resume command or by setting Continue Request in the Block Gap Control register, the Host Controller shall start at the next contiguous address stored here in the SDMA System Address register. ADMA does not use this register.

Copyright © 2011, Texas Instruments Incorporated

18.4.8 Transfer Length Configuration Register (SD_BLK)

This register shall be used for any card. SD_BLK[BLEN] is the block size register. SD_BLK[NBLK] is the block count register.

The transfer length configuration register (SD_BLK) is shown in Figure 18-44 and described in Table 18-27.

Figure 18-44. Transfer Length Configuration Register (SD_BLK)

31 16	15 12	11 0
NBLK	Reserved	BLEN
R/W-0	R-0	R/W-0

LEGENDR/W = Read/Write; R = Read only; -*n* = value after reset

Table 18-27. Transfer Length Configuration Register (SD_BLK) Field Descriptions

Bit	Field	Value	Description
31-16	NBLK		Blocks count for current transfer. This register is enabled when Block count Enable (SD_CMD[1] BCE bit) is set to 1 and is valid only for multiple block transfers. Setting the block count to 0 results no data blocks being transferred. NoteThe host controller decrements the block count after each block transfer and stops when the count reaches zero. This register can be accessed only if no transaction is executing (i.e., after a transaction has stopped). Read operations during transfers may return an invalid value and write operation will be ignored. In suspend context, the number of blocks yet to be transferred can be determined by reading this register. When restoring transfer context prior to issuing a Resume command, The local host shall restore the previously saved block count.
		0	Stop count
		1h	1 block
		2h	2 blocks
		FFFFh	65535 blocks
15-12	Reserved	0	Reserved bit field. Do not write any value.
11-0	BLEN		Transfer block size. This register specifies the block size for block data transfers. Read operations during transfers may return an invalid value, and write operations are ignored. When a CMD12 command is issued to stop the transfer, a read of the BLEN field after transfer completion (SD_STAT[1] TC bit set to 1) will not return the true byte number of data length while the stop occurs but the value written in this register before transfer is launched.
		0	No data transfer
		1h	1 byte block length
		2h	2 bytes block length
		3h	3 bytes block length
		1FFh	511 bytes block length
		200h	512 bytes block length
		7FFh	2047 bytes block length
		800h	2048 bytes block length

18.4.9 Command Argument Register (SD_ARG)

This register contains command argument specified as bit 39-8 of Command-Format. These registers must be initialized prior to sending the command itself to the card (write action into the register SD_CMD register). Only exception is for a command index specifying stuff bits in arguments, making a write unnecessary.

The command argument register (SD_ARG) is shown in Figure 18-45 and described in Table 18-28.

Figure 18-45. Command Argument Register (SD_ARG)

31	0
ARG	
R/W-0	

LEGENDR/W = Read/Write; R = Read only; -*n* = value after reset

Table 18-28. Command Argument Register (SD_ARG) Field Descriptions

Bit	Field	Value	Description
31-0	ARG		Command argument bits [31:0] .

18.4.10 Command and Transfer Mode Register (SD_CMD)

- SD_CMD[31:16] = the command register
- SD_CMD[15:0] = the transfer mode

This register configures the data and command transfers. A write into the most significant byte send the command. A write into SD_CMD[15:0] registers during data transfer has no effect.

This register can be used for any card.

NOTE: In SYSTEST mode, a write into SD_CMD register will not start a transfer.

The command and transfer mode register (SD_CMD) is shown in Figure 18-46 and described in Table 18-29.

		3Eh	CMD62 or ACMD62
		3Fh	CMD63 or ACMD63
23-22	CMD_TYPE		Command type. This register specifies three types of special commandSuspend, Resume and Abort. These bits shall be cleared to 0b00 for all other commands.
		0	Others commands
		1h	Upon CMD52 "Bus Suspend" operation
		2h	Upon CMD52 "Function Select" operation
		3h	Upon CMD12 or CMD52 "I/O Abort" command
21	DP		Data present select. This register indicates that data is present and mmc_dat line shall be used. It must be cleared to 0 in the following conditions: • Command using only mmc_cmd line • Command with no data transfer but using busy signal on mmc_dat0 • Resume command
		0	Command with no data transfer
		1	Command with data transfer
20	CICE		Command Index check enable. This bit must be set to 1 to enable index check on command response to compare the index field in the response against the index of the command. If the index is not the same in the response as in the command, it is reported as a command index error (SD_STAT[19] CIE bit set to1) NoteThe CICE bit cannot be configured for an Auto CMD12, then index check is automatically checked when this command is issued.
		0	Index check disable
		1	Index check enable
19	CCCE		Command CRC check enable. This bit must be set to 1 to enable CRC7 check on command response to protect the response against transmission errors on the bus. If an error is detected, it is reported as a command CRC error (SD_STAT[17] CCRC bit set to 1). NoteThe CCCE bit cannot be configured for an Auto CMD12, and then CRC check is automatically checked when this command is issued.
		0	CRC7 check disable
		1	CRC7 check enable
18	Reserved	0	Reserved bit field. Do not write any value.
17-16	RSP_TYPE		Response type. This bits defines the response type of the command.
		0	No response
		1h	Response Length 136 bits
		2h	Response Length 48 bits
		3h	Response Length 48 bits with busy after response

Copyright © 2011, Texas Instruments Incorporated

Table 18-29. Command and Transfer Mode Register (SD_CMD) Field Descriptions (continued)

Bit	Field	Value	Description
15-6	Reserved	0	Reserved bit field. Do not write any value.
5	MSBS		Multi/Single block select. This bit must be set to 1 for data transfer in case of multi block command. For any others command this bit shall be cleared to 0.
		0	Single block. If this bit is 0, it is not necessary to set the register SD_BLK[31:16] NBLK bits.
		1	Multi block. When Block Count is disabled (SD_CMD[1] BCE bit is cleared to 0) in Multiple block transfers (SD_CMD[5] MSBS bit is set to 1), the module can perform infinite transfer.
4	DDIR		Data transfer Direction. Select This bit defines either data transfer will be a read or a write.
		0	Data Write (host to card)
		1	Data Read (card to host)
3	Reserved	0	Reserved bit field. Do not write any value.
2	ACEN		Auto CMD12 Enable (SD cards only). When this bit is set to 1, the host controller issues a CMD12 automatically after the transfer completion of the last block. The Host Driver shall not set this bit to issue commands that do not require CMD12 to stop data transfer. In particular, secure commands do not require CMD12. For CE-ATA commands (SD_CON[12] CEATA bit set to 1), auto CMD12 is useless; therefore when this bit is set the mechanism to detect command completion signal, named CCS, interrupt is activated.
		0	Auto CMD12 disable
		1	Auto CMD12 enable or CCS detection enabled.
1	BCE		Block Count Enable (Multiple block transfers only). This bit is used to enable the block count register (SD_BLK[31:16] NBLK bits). When Block Count is disabled (SD_CMD[1] BCE bit is cleared to 0) in Multiple block transfers (SD_CMD[5] MSBS bits is set to 1), the module can perform infinite transfer.
		0	Block count disabled for infinite transfer.
		1	Block count enabled for multiple block transfer with known number of blocks
0	DE		DMA Enable. This bit is used to enable DMA mode for host data access.
		0	DMA mode disable
		1	DMA mode enable

18.4.11 Command Response[31:0] Register (SD_RSP10)

This 32-bit register holds bits positions [31:0] of command response type R1, R1b, R2, R3, R4, R5, R5b, or R6. The command response[31:0] register (SD_RSP10) is shown in Figure 18-47 and described in Table 18-30.

18.4.15 Data Register (SD_DATA)

This register is the 32-bit entry point of the buffer for read or write data transfers. The buffer size is 32bitsx256(1024 bytes). Bytes within a word are stored and read in little endian format. This buffer can be used as two 512 byte buffers to transfer data efficiently without reducing the throughput.

Sequential and contiguous access is necessary to increment the pointer correctly. Random or skipped access is not allowed. In little endian, if the local host accesses this register byte-wise or 16bit-wise, the least significant byte (bits [7:0]) must always be written/read first. The update of the buffer address is done on the most significant byte write for full 32-bit DATA register or on the most significant byte of the last word of block transfer.

Example 1Byte or 16-bit access

- Mbyteen[3:0]=0001 (1-byte) => Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=1100 (2-bytes) OK
- Mbyteen[3:0]=0001 (1-byte) => Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=0100 (1-byte) OK
- Mbyteen[3:0]=0001 (1-byte) => Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=1000 (1-byte) Bad

The data register (SD_DATA) is shown in Figure 18-51 and described in Table 18-34.

Figure 18-51. Data Register (SD_DATA)

31	0
DATA	
R/W-0	

LEGENDR/W = Read/Write; R = Read only; *-n* = value after reset

Table 18-34. Data Register (SD_DATA) Field Descriptions

Bit	Field	Value	Description
31-0	DATA		Data register [31:0]. In functional mode (SD_CON[4] MODE bit set to the default value 0): A read access to this register is allowed only when the buffer read enable status is set to 1 (SD_PSTATE[11] BRE bit), otherwise a bad access (SD_STAT[29] BADA bit) is signaled. A write access to this register is allowed only when the buffer write enable status is set to 1 (SD_PSTATE[10] BWE bit), otherwise a bad access (SD_STAT[29] BADA bit) is signaled and the data is not written.

Copyright © 2011, Texas Instruments Incorporated

18.4.16 Present State Register (SD_PSTATE)

The Host can get the status of the Host controller from this 32-bit read only register. The present state register (SD_PSTATE) is shown in Figure 18-52 and described in Table 18-35.

Figure 18-52. Present State Register (SD_PSTATE)

31	25	24	23	20	19	18	17	16
Reserved		CLEV	DLEV		WP	CDPL	CSS	CINS
R-0		R-x	R-x		R-0	R-0	R-0	R-0

15	12	11	10	9	8	7	3	2	1	0
Reserved		BRE	BWE	RTA	WTA	Reserved		DLA	DATI	CMDI
R-0		R-0	R-0	R-0	R-0	R-0		R-0	R-0	R-0

LEGENDR/W = Read/Write; R = Read only; -*n* = value after reset

Table 18-35. Present State Register (SD_PSTATE) Field Descriptions

Bit	Field	Value	Description
31-25	Reserved	0	Reserved bit field. Do not write any value.
24	CLEV		mmc_cmd line signal level. This status is used to check the mmc_cmd line level to recover from errors, and for debugging. The value of this register after reset depends on the mmc_cmd line level at that time.
		Read 0	The mmc_cmd line level is 0.
		Read 1	The mmc_cmd line level is 1.
23-20	DLEV		mmc_dat[3:0] line signal level • mmc_dat3 => bit 23 • mmc_dat2 => bit 22 • mmc_dat1 => bit 21 • mmc_dat0 => bit 20 This status is used to check mmc_dat line level to recover from errors, and for debugging. This is especially useful in detecting the busy signal level from mmc_dat0 . The value of these registers after reset depends on the mmc_dat lines level at that time.
19	WP		Write Protect. MMC/SD/SDIO1 only. SDIO cards only. This bit reflects the write protect input pin (SDWP) level. The value of this register after reset depends one the protect input pin (SDWP) level at that time.
		Read 0	If SD_CON[8] WPP is cleared to 0 (default), the card is write protected, otherwise the card is not write protected.
		Read 1	If SD_CON[8] WPP is cleared to 0 (default), the card is not write protected, otherwise the card is write protected.
18			Card Detect Pin Level. MMC/SD/SDIO1 only. SDIO cards only. This bit reflects the inverse value of the card detect input pin (SDCD). Debouncing is not performed on this bit and is valid only when Card State is stable. (SD_PSTATE[17] is set to 1). This bit must be debounced by software. The value of this register after reset depends on the card detect input pin (SDCD) level at that time.
		Read 0	The value of the card detect input pin (SDCD) is 1.
		Read 1	The value of the card detect input pin (SDCD) is 0.
17			Card State Stable. This bit is used for testing. It is set to 1 only when Card Detect Pin Level is stable (SD_PSTATE[18] CPDL). Debouncing is performed on the card detect input pin (SDCD) to detect card stability. This bit is not affected by software reset.
		Read 0	Reset or Debouncing.
		Read 1	Reset or Debouncing.

Copyright © 2011, Texas Instruments Incorporated

Table 18-35. Present State Register (SD_PSTATE) Field Descriptions (continued)

Bit	Field	Value	Description
16			Card inserted. This bit is the debounced value of the card detect input pin (SDCD). An inactive to active transition of the card detect input pin (SDCD) will generate a card insertion interrupt (SD_STAT[CINS]). A active to inactive transition of the card detect input pin (SDCD) will generate a card removal interrupt (SD_STAT[REM]). This bit is not affected by a software reset.
		Read 0	If SD_CON[CDP] is cleared to 0 (default), no card is detected. The card may have been removed from the card slot. If SD_CON[CDP] is set to 1, the card has been inserted.
		Read 1	If SD_CON[CDP] is cleared to 0 (default), the card has been inserted from the card slot. If SD_CON[CDP] is set to 1, no card is detected. The card may have been removed from the card slot.
15-12	Reserved	0	Reserved bit field. Do not write any value.
11	BRE		Buffer read enable. This bit is used for non-DMA read transfers. It indicates that a complete block specified by SD_BLK[10:0] BLEN bits has been written in the buffer and is ready to be read. It is cleared to 0 when the entire block is read from the buffer. It is set to 1 when a block data is ready in the buffer and generates the Buffer read ready status of interrupt (SD_STAT[5] BRR bit).
		Read 0	Read BLEN bytes disable
		Read 1	Read BLEN bytes enable. Readable data exists in the buffer.
10	BWE		Buffer Write enable. This status is used for non-DMA write transfers. It indicates if space is available for write data.
		Read 0	There is no room left in the buffer to write BLEN bytes of data.
		Read 1	There is enough space in the buffer to write BLEN bytes of data.
9	RTA		Read transfer active. This status is used for detecting completion of a read transfer. It is set to 1 after the end bit of read command or by activating a continue request (SD_HCTL[17] CR bit) following a stop at block gap request. This bit is cleared to 0 when all data have been read by the local host after last block or after a stop at block gap request.
		Read 0	No valid data on the mmc_dat lines.
		Read 1	Read data transfer on going.
8	WTA		Write transfer active. This status indicates a write transfer active. It is set to 1 after the end bit of write command or by activating a continue request (SD_HCTL[17] CR bit) following a stop at block gap request. This bit is cleared to 0 when CRC status has been received after last block or after a stop at block gap request.
		Read 0	No valid data on the mmc_dat lines.
		Read 1	Write data transfer on going.
7-3	Reserved	0	Reserved bit field. Do not write any value.
2	DLA		mmc_dat line active. This status bit indicates whether one of the mmc_dat lines is in use. In the case of read transactions (card to host)This bit is set to 1 after the end bit of read command or by activating continue request SD_HCTL[17] CR bit. This bit is cleared to 0 when the host controller received the end bit of the last data block or at the beginning of the read wait mode. In the case of write transactions (host to card)This bit is set to 1 after the end bit of write command or by activating continue request SD_HCTL[17] CR bit. This bit is cleared to 0 on the end of busy event for the last block; host controller must wait 8 clock cycles with line not busy to really consider not "busy state" or after the busy block as a result of a stop at gap request.
		Read 0	mmc_dat line inactive
		Read 1	mmc_dat line active
1	DATI		Command inhibit (mmc_dat). This status bit is generated if either mmc_dat line is active (SD_PSTATE[2] DLA bit) or Read transfer is active (SD_PSTATE[9] RTA bit) or when a command with busy is issued. This bit prevents the local host to issue a command. A change of this bit from 1 to 0 generates a transfer complete interrupt (SD_STAT[1] TC bit).
		Read 0	Issuing of command using the mmc_dat lines is allowed
		Read 1	Issuing of command using mmc_dat lines is not allowed

Copyright © 2011, Texas Instruments Incorporated

Table 18-35. Present State Register (SD_PSTATE) Field Descriptions (continued)

Bit	Field	Value	Description
0	CMDI		Command inhibit(mmc_cmd). This status bit indicates that the mmc_cmd line is in use. This bit is cleared to 0 when the most significant byte is written into the command register. This bit is not set when Auto CMD12 is transmitted. This bit is cleared to 0 in either the following cases: • After the end bit of the command response, excepted if there is a command conflict error (SD_STAT[17] CCRC bit or SD_STAT[18] CEB bit set to 1) or a Auto CMD12 is not executed (SD_AC12[0] ACNE bit). • After the end bit of the command without response (SD_CMD[17:16] RSP_TYPE bits set to "00"). In case of a command data error is detected (SD_STAT[19] CTO bit set to 1), this register is not automatically cleared.
		Read 0	Issuing of command using mmc_cmd line is allowed
		Read 1	Issuing of command using mmc_cmd line is not allowed

18.4.17 Control Register (SD_HCTL)

This register defines the host controls to set power, wake-up and transfer parameters.

- SD_HCTL[31:24] = Wake-up control
- SD_HCTL[23:16] = Block gap control
- SD_HCTL[15:8] = Power control
- SD_HCTL[7:0] = Host control

NOTE: If your device does not support MMC cards, then those bits in this register which are meant for MMC card use should be assumed to be reserved.

The control register (SD_HCTL) is shown in Figure 18-53 and described in Table 18-36.

Figure 18-53. Control Register (SD_HCTL)

31	28	27	26	25	24	23	20	19	18	17	16
Reserved		OBWE	REM	INS	IWE	Reserved		IBG	RWC	CR	SBGR
R-0		R/W-0	R/W-0	R/W-0	R/W-0	R-0		R/W-0	R/W-0	R/W-0	R/W-0

15	12	11	9	8	7	6	5	4	3	2	1	0
Reserved		SDVS		SDBP	CDSS	CDTL	Rsvd	DMAS		HSPE	DTW	Rsvd
R-0		R/W-0		R/W-0	R/W-0	R/W-0	R-0	R/W-2h		R/W-0	R/W-0	R-0

LEGENDR/W = Read/Write; R = Read only; *-n* = value after reset

Table 18-36. Control Register (SD_HCTL) Field Descriptions

Bit	Field	Value	Description
31-28	Reserved	0	Reserved bit field. Do not write any value.
27	OBWE		Wake-up event enable for 'out-of-band' Interrupt. This bit enables wake-up events for 'out-of-band' assertion. Wake-up is generated if the wake-up feature is enabled (SD_SYSCONFIG[2] ENAWAKEUP bit). The write to this register is ignored when SD_CON[14] OBIE bit is not set.
		0	Disable wake-up on 'out-of-band' Interrupt
		1	Enable wake-up on 'out-of-band' Interrupt
26	REM		Wake-up event enable on SD card removal. This bit enables wake-up events for card removal assertion. Wake-up is generated if the wake-up feature is enabled (SD_SYSCONFIG[2] ENAWAKEUP bit).
		0	Disable wake-up on card removal
		1	Enable wake-up on card removal
25	INS		Wake-up event enable on SD card insertion This bit enables wake-up events for card insertion assertion. Wake-up is generated if the wake-up feature is enabled (SD_SYSCONFIG[2] ENAWAKEUP bit).
		0	Disable wake-up on card insertion
		1	Enable wake-up on card insertion
24	IWE		Wake-up event enable on SD card interrupt. This bit enables wake-up events for card interrupt assertion. Wake-up is generated if the wake-up feature is enabled (SD_SYSCONFIG[2] ENAWAKEUP bit) and enable status bit is set (SD_IE[8] CIRQ_ENABLE bit).
		0	Disable wake-up on card interrupt
		1	Enable wake-up on card interrupt
23-20	Reserved	0	Reserved bit field. Do not write any value.
19	IBG		Interrupt block at gap. This bit is valid only in 4-bit mode of SDIO card to enable interrupt detection in the interrupt cycle at block gap for a multiple block transfer. For MMC cards and for SD card this bit should be cleared to 0.
		0	Disable interrupt detection at the block gap in 4-bit mode
		1	Enable interrupt detection at the block gap in 4-bit mode

Copyright © 2011, Texas Instruments Incorporated

Table 18-36. Control Register (SD_HCTL) Field Descriptions (continued)

Bit	Field	Value	Description
18	RWC		Read wait control. The read wait function is optional only for SDIO cards. If the card supports read wait, this bit must be enabled, then requesting a stop at block gap (SD_HCTL[16] SBGR bit) generates a read wait period after the current end of block. Be careful, if read wait is not supported it may cause a conflict on mmc_dat line.
		0	Disable read wait control. Suspend/resume cannot be supported.
		1	Enable read wait control
17	CR		Continue request. This bit is used to restart a transaction that was stopped by requesting a stop at block gap (SD_HCTL[16] SBGR bit). Set this bit to 1 restarts the transfer. The bit is automatically cleared to 0 by the host controller when transfer has restarted, that is, mmc_dat line is active (SD_PSTATE[2] DLA bit) or transferring data (SD_PSTATE[8] WTA bit). The Stop at block gap request must be disabled (SD_HCTL[16] SBGR bit =0) before setting this bit.
		0	No affect
		1	Transfer restart
16	SBGR		Stop at block gap request. This bit is used to stop executing a transaction at the next block gap. The transfer can restart with a continue request (SD_HCTL[17] CR bit) or during a suspend/resume sequence. In case of read transfer, the card must support read wait control. In case of write transfer, the host driver shall set this bit after all block data written. Until the transfer completion (SD_STAT[1] TC bit set to 1), the host driver shall leave this bit set to 1.If this bit is set, the local host shall not write to the data register (SD_DATA).
		0	Transfer mode
		1	Stop at block gap
15-12	Reserved	0	Reserved bit field. Do not write any value.
11-9	SDVS		SD bus voltage select (All cards). The host driver should set these bits to select the voltage level for the card according to the voltage supported by the system (SD_CAPA[26] VS18 bit, SD_CAPA[25] VS30 bit, SD_CAPA[24] VS33 bit) before starting a transfer.
			MMCHS2. This field must be set to 5h.
			MMCHS3. This field must be set to 5h.
		5h	1.8 V (Typical)
		6h	3.0 V (Typical)
		7h	3.3 V (Typical)
8	SDBP		SD bus power. Before setting this bit, the host driver shall select the SD bus voltage (SD_HCTL[11:9] SDVS bits). If the host controller detects the No card state, this bit is automatically cleared to 0. If the module is power off, a write in the command register (SD_CMD) will not start the transfer. A write to this bit has no effect if the selected SD bus voltage is not supported according to capability register (SD_CAPA[VS*]).
		0	Power off
		1	Power on
7	CDSS		Card Detect Signal Selection. This bit selects source for the card detection. When the source for the card detection is switched, the interrupt should be disabled during the switching period by clearing the Interrupt Status/Signal Enable register in order to mask unexpected interrupt being caused by the glitch. The Interrupt Status/Signal Enable should be disabled during over the period of debouncing.
		0	SDCD# is selected (for normal use).
		1	The Card Detect Test Level is selected (for test purposes).
6	CDTL		Card Detect Test Level. This bit is enabled while the Card Detect Signal Selection is set to 1 and it indicates card inserted or not.
		0	No card
		1	Card inserted.
5	Reserved	0	Reserved bit field. Do not write any value.

Copyright © 2011, Texas Instruments Incorporated

Table 18-36. Control Register (SD_HCTL) Field Descriptions (continued)

Bit	Field	Value	Description
4-3	DMAS		DMA Select. One of the supported DMA modes can be selected. The host driver shall check support of DMA modes by referencing the Capabilities register. Use of selected DMA is determined by DMA Enable of the Transfer Mode register. This register is only meaningful when MADMA_EN is set to 1. When MADMA_EN is cleared to 0 the bit field is read only and returned value is 0.
		0-1h	Reserved
		2h	32-bit Address ADMA2 is selected.
		3h	Reserved
2	HSPE		High Speed Enable. Before setting this bit, the Host Driver shall check the High Speed Support in the Capabilities register. If this bit is cleared to 0 (default), the Host Controller outputs CMD line and DAT lines at the falling edge of the SD Clock. If this bit is set to 1, the Host Controller outputs CMD line and DAT lines at the rising edge of the SD Clock. This bit shall not be set when dual data rate mode is activated in SD_CON[DDR].
		0	Normal speed mode
		1	High speed mode
1	DTW		Data transfer width. This bit must be set following a valid SET_BUS_WIDTH command (ACMD6) with the value written in bit 1 of the argument. Prior to this command, the SD card configuration register (SCR) must be verified for the supported bus width by the SD card.
		0	1-bit Data width (mmc_dat0 used)
		1	4-bit Data width (mmc_dat[3:0] used)
0	Reserved	0	Reserved bit field. Do not write any value.

Copyright © 2011, Texas Instruments Incorporated

18.4.18 SD System Control Register (SD_SYSCTL)

This register defines the system controls to set software resets, clock frequency management and data timeout.

- SD_SYSCTL[31:24] = Software resets
- SD_SYSCTL[23:16] = Timeout control
- SD_SYSCTL[15:0] = Clock control

The SD system control register (SD_SYSCTL) is shown in Figure 18-54 and described in Table 18-37.

Figure 18-54. SD System Control Register (SD_SYSCTL)

Bit	Field	Value	Description
31-27	Reserved	0	Reserved bit field. Do not write any value.
26	SRD		Software reset for mmc_dat line. This bit is set to 1 for reset and released to 0 when completed. mmc_dat finite state machine in both clock domain are also reset. These registers are cleared by the SD_SYSCTL[26] SRD bit: • SD_DATA • SD_PSTATEBRE, BWE, RTA, WTA, DLA and DATI • SD_HCTLSBGR and CR • SD_STATBRR, BWR, BGE and TC Interconnect and MMC buffer data management is reinitialized. **Note**If a soft reset is issued when an interrupt is asserted, data may be lost.
		0	Reset completed
		1	Software reset for mmc_dat line
25	SRC		Software reset for mmc_cmd line. This bit is set to 1 for reset and released to 0 when completed. mmc_cmd finite state machine in both clock domain are also reset. These registers are cleared by the SD_SYSCTL[25] SRC bit: • SD_PSTATECMDI • SD_STATCC Interconnect and MMC command status management is reinitialized. **Note**If a soft reset is issued when an interrupt is asserted, data may be lost.
		0	Reset completed
		1	Software reset for mmc_cmd line
24	SRA		Software reset for all. This bit is set to 1 for reset , and released to 0 when completed. This reset affects the entire host controller except for the card detection circuit and capabilities registers.
		0	Reset completed
		1	Software reset for all the design
23-20	Reserved	0	Reserved bit field. Do not write any value.

Copyright © 2011, Texas Instruments Incorporated

Table 18-37. SD System Control Register (SD_SYSCTL) Field Descriptions (continued)

Bit	Field	Value	Description
19-16	DTO		Data timeout counter value and busy timeout. This value determines the interval by which mmc_dat lines timeouts are detected. The host driver needs to set this bit field based on: • The maximum read access time (NAC) (Refer to the SD Specification Part1 Physical Layer) • The data read access time values (TAAC and NSAC) in the card specific data register (CSD) of the card • The timeout clock base frequency (SD_CAPA[5:0] TCF bits) If the card does not respond within the specified number of cycles, a data timeout error occurs (SD_STAT[20] DTO bit). The SD_SYSCTL[19,16] DTO bit field is also used to check busy duration, to generate busy timeout for commands with busy response or for busy programming during a write command. Timeout on CRC status is generated if no CRC token is present after a block write.
		0	TCF x 2^13
		1h	TCF x 2^14
		Eh	TCF x 2^27
		Fh	Reserved
15-6	CLKD		Clock frequency select. These bits define the ratio between a reference clock frequency (system dependant) and the output clock frequency on the mmc_clk pin of either the memory card (MMC, SD, or SDIO).
		0	Clock Ref bypass
		1h	Clock Ref bypass
		2h	Clock Ref / 2
		3h	Clock Ref / 3
		3FFh	Clock Ref / 1023
5-3	Reserved	0	Reserved bit field. Do not write any value.
2	CEN		Clock enable. This bit controls if the clock is provided to the card or not.
		0	The clock is not provided to the card . Clock frequency can be changed .
		1	The clock is provided to the card and can be automatically gated when SD_SYSCONFIG[0] AUTOIDLE bit is set to 1 (default value) . The host driver shall wait to set this bit to 1 until the Internal clock is stable (SD_SYSCTL[1] ICS bit).
1	ICS		Internal clock stable (status)This bit indicates either the internal clock is stable or not.
		0	The internal clock is not stable.
		1	The internal clock is stable after enabling the clock (SD_SYSCTL[0] ICE bit) or after changing the clock ratio (SD_SYSCTL[15:6] CLKD bits).
0	ICE		Internal clock enable. This register controls the internal clock activity. In very low power state, the internal clock is stopped. NoteThe activity of the debounce clock (used for wake-up events) and the interface clock (used for reads and writes to the module register map) are not affected by this register.
		0	The internal clock is stopped (very low power state).
		1	The internal clock oscillates and can be automatically gated when SD_SYSCONFIG[0] AUTOIDLE bit is set to 1 (default value).

Copyright © 2011, Texas Instruments Incorporated

18.4.19 Interrupt Status Register (SD_STAT)

The interrupt status regroups all the status of the module internal events that can generate an interrupt.

- SD_STAT[31:16] = Error Interrupt Status
- SD_STAT[15:0] = Normal Interrupt Status

The error bits are located in the upper 16 bits of the SD_STAT register. All bits are cleared by writing a 1 to them. Additionally, bits 15 and 8 serve as special error bits. These cannot be cleared by writing a 1 to them. Bit 15 (ERRI) is automatically cleared when the error causing to ERRI to be set is handled. (that is, when bits 31:16 are cleared, bit 15 will be automatically cleared). Bit 8 (CIRQ) is cleared by writing a 0 to SD_IE[8] (masking the interrupt) and servicing the interrupt.

The interrupt status register (SD_STAT) is shown in Figure 18-55 and described in Table 18-38.

Figure 18-55. Interrupt Status Register (SD_STAT)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

LEGENDR/W = Read/Write; R = Read only; -*n* = value after reset

Table 18-38. Interrupt Status Register (SD_STAT) Field Descriptions

Bit	Field	Value	Description
31-30	Reserved	0	Reserved bit field. Do not write any value
29	BADA		Bad access to data space. This bit is set automatically to indicate a bad access to buffer when not allowed: • During a read access to the data register (SD_DATA) while buffer reads are not allowed (SD_PSTATE[11] BRE bit =0) • During a write access to the data register (SD_DATA) while buffer writes are not allowed (SD_PSTATE[10] BWE bit=0)
		Read 0	No interrupt
		Write 0	Status bit unchanged
		Read 1	Bad access
		Write 1	Status is cleared.
28	CERR		Card error. This bit is set automatically when there is at least one error in a response of type R1, R1b, R6, R5 or R5b. Only bits referenced as type E (error) in status field in the response can set a card status error. An error bit in the response is flagged only if corresponding bit in card status response error SD_CSRE in set. There is no card error detection for autoCMD12 command. The host driver shall read SD_RSP76 register to detect error bits in the command response.
		Read 0	No error
		Write 0	Status bit unchanged
		Read 1	Card error
		Write 1	Status is cleared.
27-26	Reserved	0	Reserved bit field. Do not write any value

Copyright © 2011, Texas Instruments Incorporated

Table 18-38. Interrupt Status Register (SD_STAT) Field Descriptions (continued)

Bit	Field	Value	Description
25	ADMAE		ADMA Error. This bit is set when the Host Controller detects errors during ADMA based data transfer. The state of the ADMA at an error occurrence is saved in the ADMA Error Status Register. In addition, the Host Controller generates this interrupt when it detects invalid descriptor data (Valid=0) at the ST_FDS state. ADMA Error State in the ADMA Error Status indicates that an error occurs in ST_FDS state. The Host Driver may find that Valid bit is not set at the error descriptor.
		Read 0	No interrupt
		Write 0	Status bit unchanged
		Read 1	ADMA error
		Write 1	Status is cleared.
24	ACE		Auto CMD12 error. This bit is set automatically when one of the bits in Auto CMD12 Error status register has changed from 0 to 1.
		Read 0	No error
		Write 0	Status bit unchanged
		Read 1	AutoCMD12 error
		Write 1	Status is cleared.
23	Reserved	0	Reserved bit field. Do not write any value
22	DEB		Data End Bit error. This bit is set automatically when detecting a 0 at the end bit position of read data on mmc_dat line or at the end position of the CRC status in write mode.
		Read 0	No error
		Write 0	Status bit unchanged
		Read 1	Data end bit error
		Write 1	Status is cleared.
21	DCRC		Data CRC Error. This bit is set automatically when there is a CRC16 error in the data phase response following a block read command or if there is a 3-bit CRC status different of a position "010" token during a block write command.
		Read 0	No error
		Write 0	Status bit unchanged
		Read 1	Data CRC error
		Write 1	Status is cleared.
20	DTO		Data timeout error. This bit is set automatically according to the following conditions: • Busy timeout for R1b, R5b response type • Busy timeout after write CRC status • Write CRC status timeout • Read data timeout
		Read 0	No error
		Write 0	Status bit unchanged
		Read 1	Time out
		Write 1	Status is cleared.
19	CIE		Command index error. This bit is set automatically when response index differs from corresponding command index previously emitted. It depends on the enable bit (SD_CMD[20] CICE).
		Read 0	No error
		Write 0	Status bit unchanged
		Read 1	Command index error
		Write 1	Status is cleared.

Copyright © 2011, Texas Instruments Incorporated

Table 18-38. Interrupt Status Register (SD_STAT) Field Descriptions (continued)

Bit	Field	Value	Description
18	CEB		Command end bit error. This bit is set automatically when detecting a 0 at the end bit position of a command response.
		Read 0	No error
		Write 0	Status bit unchanged
		Read 1	Command end bit error
		Write 1	Status is cleared.
17	CCRC		Command CRC error. This bit is set automatically when there is a CRC7 error in the command response depending on the enable bit (SD_CMD[19] CCCE).
		Read 0	No error
		Write 0	Status bit unchanged
		Read 1	Command CRC error
		Write 1	Status is cleared.
16	CTO		Command timeout error. This bit is set automatically when no response is received within 64 clock cycles from the end bit of the command. For commands that reply within 5 clock cycles - the timeout is still detected at 64 clock cycles.
		Read 0	No error
		Write 0	Status bit unchanged
		Read 1	Time Out
		Write 1	Status is cleared.
15	ERRI		Error interrupt. If any of the bits in the Error Interrupt Status register (SD_STAT[31:16]) are set, then this bit is set to 1. Therefore the host driver can efficiently test for an error by checking this bit first. Writes to this bit are ignored.
		Read 0	No interrupt
		Read 1	Error interrupt event(s) occurred
14-11	Reserved	0	Reserved bit field. Do not write any value
10	BSR		Boot Status Received Interrupt. This bit is set automatically when SD_CON[BOOT] is set 1 or 2 and a boot status is received on DAT[0] line. This interrupt is only useful for MMC card.
		Read 0	No interrupt
		Write 0	Status bit unchanged
		Read 1	Boot Status Received Interrupt occurred.
		Write 1	Status is cleared.
9	OBI		Out-of-band interrupt (This interrupt is only useful for MMC card). This bit is set automatically when SD_CON[14] OBIE bit is set and an out-of-band interrupt occurs on OBI pin. The interrupt detection depends on polarity controlled by SD_CON[13] OBIP bit. The out-of-band interrupt signal is a system specific feature for future use, this signal is not required for existing specification implementation.
		Read 0	No out-of-band interrupt
		Write 0	Status bit unchanged
		Read 1	Interrupt out-of-band occurs
		Write 1	Status is cleared.

Copyright © 2011, Texas Instruments Incorporated

Table 18-38. Interrupt Status Register (SD_STAT) Field Descriptions (continued)

Bit	Field	Value	Description
8	CIRQ		Card interrupt. This bit is only used for SD and SDIO cards. In 1-bit mode, interrupt source is asynchronous (can be a source of asynchronous wake-up). In 4-bit mode, interrupt source is sampled during the interrupt cycle. In CE-ATA mode, interrupt source is detected when the card drives mmc_cmd line to zero during one cycle after data transmission end. All modes above are fully exclusive. The controller interrupt must be clear by setting SD_IE[8] CIRQ_ENABLE to 0, then the host driver must start the interrupt service with card (clearing card interrupt status) to remove card interrupt source. Otherwise the Controller interrupt will be reasserted as soon as SD_IE[8] CIRQ_ENABLE is set to 1. Writes to this bit are ignored.
		Read 0	No card interrupt
		Read 1	Generate card interrupt
7	CREM		Card Removal. This bit is set automatically when SD_PSTATE[CINS] changes from 1 to 0. A clear of this bit doesn't affect Card inserted present state (SD_PSTATE[CINS]).
		Read 0	Card State stable or debouncing
		Write 0	Status bit unchanged
		Read 1	Card Removed
		Write 1	Status is cleared
6	CINS		Card Insertion. This bit is set automatically when SD_PSTATE[CINS] changes from 0 to 1. A clear of this bit doesn't affect Card inserted present state (SD_PSTATE[CINS]).
		Read 0	Card State stable or debouncing
		Write 0	Status bit unchanged
		Read 1	Card inserted
		Write 1	Status is cleared.
5	BRR		Buffer read ready. This bit is set automatically during a read operation to the card (see class 2 - block oriented read commands) when one block specified by the SD_BLK[10:0] BLEN bit field is completely written in the buffer. It indicates that the memory card has filled out the buffer and that the local host needs to empty the buffer by reading it. NoteIf the DMA receive-mode is enabled, this bit is never set; instead a DMA receive request to the main DMA controller of the system is generated.
		Read 0	Not ready to read buffer
		Write 0	Status bit unchanged
		Read 1	Ready to read buffer
		Write 1	Status is cleared.
4	BWR		Buffer write ready. This bit is set automatically during a write operation to the card (see class 4 - block oriented write command) when the host can write a complete block as specified by SD_BLK[10:0] BLEN. It indicates that the memory card has emptied one block from the buffer and that the local host is able to write one block of data into the buffer. NoteIf the DMA transmit mode is enabled, this bit is never set; instead, a DMA transmit request to the main DMA controller of the system is generated.
		Read 0	Not ready to write buffer
		Write 0	Status bit unchanged
		Read 1	Ready to write buffer
		Write 1	Status is cleared.
3	DMA		DMA Interrupt. This status is set when an interrupt is required in the ADMA instruction and after the data transfer completion.
		Read 0	DMA Interrupt detected
		Write 0	Status bit unchanged
		Read 1	No DMA Interrupt
		Write 1	Status is cleared.

Copyright © 2011, Texas Instruments Incorporated

Table 18-38. Interrupt Status Register (SD_STAT) Field Descriptions (continued)

Bit	Field	Value	Description
2	BGE		Block gap event. When a stop at block gap is requested (SD_HCTL[16] SBGR bit), this bit is automatically set when transaction is stopped at the block gap during a read or write operation. This event does not occur when the stop at block gap is requested on the last block. In read mode, a 1-to-0 transition of the mmc_dat line active status (SD_PSTATE[2] DLA bit) between data blocks generates a Block gap event interrupt.
		Read 0	No block gap event
		Write 0	Status bit unchanged
		Read 1	Transaction stopped at block gap
		Write 1	Status is cleared
1	TC		Transfer completed. This bit is always set when a read/write transfer is completed or between two blocks when the transfer is stopped due to a stop at block gap request (SD_HCTL[16] SBGR bit). This bit is also set when exiting a command in a busy state (if the command has a busy notification capability). In Read modeThis bit is automatically set on completion of a read transfer (SD_PSTATE[9] RTA bit). In write modeThis bit is set automatically on completion of the mmc_dat line use (SD_PSTATE[2] DLA bit).
		Read 0	No transfer complete
		Write 0	Status bit unchanged
		Read 1	Data transfer complete
		Write 1	Status is cleared
0	CC		Command complete. This bit is set when a 1-to-0 transition occurs in the register command inhibit (SD_PSTATE[0] CMDI bit) If the command is a type for which no response is expected, then the command complete interrupt is generated at the end of the command. A command timeout error (SD_STAT[16] CTO bit) has higher priority than command complete (SD_STAT[0] CC bit). If a response is expected but none is received, then a command timeout error is detected and signaled instead of the command complete interrupt.
		Read 0	No command complete
		Write 0	Status bit unchanged
		Read 1	Command complete
		Write 1	Status is cleared

18.4.20 Interrupt SD Enable Register (SD_IE)

This register allows to enable/disable the module to set status bits, on an event-by-event basis.

- SD_IE[31:16] = Error Interrupt Status Enable
- SD_IE[15:0] = Normal Interrupt Status Enable

The interrupt SD enable register (SD_IE) is shown in Figure 18-56 and described in Table 18-39.

18.4.21 Interrupt Signal Enable Register (SD_ISE)

This register allows you to enable/disable the module to set status bits, on an event-by-event basis.

- SD_ISE[31:16] = Error Interrupt Signal Enable
- SD_ISE[15:0] = Normal Interrupt Signal Enable

The Interrupt Signal Enable Register (SD_ISE) is shown in Figure 18-57 and described in Table 18-40.

18.4.22 Auto CMD12 Error Status Register (SD_AC12)

The host driver may determine which of the errors cases related to Auto CMD12 has occurred by checking this SD_AC12 register when an auto CMD12 error interrupt occurs.

This register is valid only when auto CMD12 is enabled (SD_CMD[2] ACEN bit) and auto CMD12Error (SD_STAT[24] ACE bit) is set to 1.

NOTE: These bits are automatically reset when starting a new adtc command with data.

The auto CMD12 error status register (SD_AC12) is shown in Figure 18-58 and described in Table 18-41.

Figure 18-58. Auto CMD12 Error Status Register (SD_AC12)

31	8	7	6	5	4	3	2	1	0
Reserved		CNI	Reserved		ACIE	ACEB	ACCE	ACTO	ACNE
R-0		R-0	R-0		R-0	R-0	R-0	R-0	R-0

LEGENDR/W = Read/Write; R = Read only; -*n* = value after reset

Table 18-41. Auto CMD12 Error Status Register (SD_AC12) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved bit field. Do not write any value.
7	CNI		Command not issue by auto CMD12 error. If this bit is set to 1, it means that pending command is not executed due to auto CMD12 error ACEB, ACCE, ACTO, or ACNE.
		Read 0	Not error
		Read 1	Command not issued
6-5	Reserved	0	Reserved bit field. Do not write any value.
4	ACIE		Auto CMD12 index error. This bit is a set to 1 when response index differs from corresponding command auto CMD12 index previously emitted.
			This bit depends on the command index check enable (SD_CMD[20] CICE bit).
		Read 0	No error
		Read 1	Auto CMD12 index error
3	ACEB		Auto CMD12 end bit error. This bit is set to 1 when detecting a 0 at the end bit position of auto CMD12 command response.
		Read 0	No error
		Read 1	AutoCMD12 end bit error
2	ACCE		Auto CMD12 CRC error. This bit is automatically set to 1 when a CRC7 error is detected in the auto CMD12 command response depending on the enable in the SD_CMD[19] CCCE bit.
		Read 0	No error
		Read 1	Auto CMD12 CRC error
1	ACTO		Auto CMD12 timeout error. This bit is set to 1 if no response is received within 64 clock cycles from the end bit of the auto CMD12 command.
		Read 0	No error
		Read 1	Auto CMD12 time out
0	ACNE		Auto CMD12 not executed. This bit is set to 1 if multiple block data transfer command has started and if an error occurs in command before auto CMD12 starts.
		Read 0	Auto CMD12 executed
		Read 1	Auto CMD12 not executed

18.4.23 Capabilities Register (SD_CAPA)

This register lists the capabilities of the MMC/SD/SDIO host controller. The capabilities register (SD_CAPA) is shown in Figure 18-59 and described in Table 18-42.

Figure 18-59. Capabilities Register (SD_CAPA)

31	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 18-42. Capabilities Register (SD_CAPA) Field Descriptions

Bit	Field	Value	Description
31-29	Reserved	0	Reserved bit field. Do not write any value.
28	64BIT		64 Bit System Bus Support. Setting 1 to this bit indicates that the Host Controller supports 64-bit address descriptor mode and is connected to 64-bit address system bus.
		Read 0	32 bit System bus address
		Read 1	64 bit System bus address
27	Reserved	0	Reserved bit. Any write to this bit results in 0.
26	VS18		Voltage support 1.8 V. Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initialization. This register is only reinitialized by a hard reset (via mmc_RESET signal). Note. The device supports both 1.8v and 3.3v cards. However, MMC/SD/SDIO0 and MMC/SD/SDIO1 must be configured to the same voltage. You cannot configure MMC/SD/SDIO0, for example, to be 1.8v and MMC/SD/SDIO1 to be 3.3v. MMC/SD/SDIO2 is independent of the other two and can be set to either voltage regardless of what the other two are set to.
		Read 0	1.8 V not supported
		Write 0	1.8 V not supported
		Read 1	1.8 V supported
		Write 1	1.8 V supported
25	VS30		Voltage support 3.0V. Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initialization. This register is only reinitialized by a hard reset (via mmc_RESET signal) Note. The device supports both 1.8v and 3.3v cards, however MMC/SD/SDIO0 and MMC/SD/SDIO1 must be configured to the same voltage. You cannot configure MMC/SD/SDIO0, for example, to be 1.8v and MMC/SD/SDIO1 to be 3.3v. MMC/SD/SDIO2 is independent of the other two and can be set to either voltage regardless of what the other two are set to.
		Read 0	3.0 V not supported
		Write 0	3.0 V not supported
		Read 1	3.0 V supported
		Write 1	3.0 V supported
24	VS33		Voltage support 3.3V. Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initialization. This register is only reinitialized by a hard reset (via mmc_RESET signal)
		Read 0	3.3 V not supported
		Write 0	3.3 V not supported
		Read 1	3.3 V supported
		Write 1	3.3 V supported

Table 18-42. Capabilities Register (SD_CAPA) Field Descriptions (continued)

Bit	Field	Value	Description
23	SRS		Suspend/resume support (SDIO cards only). This bit indicates whether the host controller supports Suspend/Resume functionality.
		Read 0	The Host controller does not suspend/resume functionality.
		Read 1	The Host controller supports suspend/resume functionality.
22	DS		DMA support. This bit indicates that the Host controller is able to use DMA to transfer data between system memory and the Host controller directly.
		Read 0	DMA not supported
		Read 1	DMA supported
21	HSS		High-speed support. This bit indicates that the host controller supports high speed operations and can supply an up-to-52 MHz clock to the card.
		Read 0	DMA not supported
		Read 1	DMA supported
20	Reserved	0	Reserved bit field. Do not write any value.
19	AD2S		This bit indicates whether the Host Controller is capable of using ADMA2. It depends on setting of generic parameter MADMA_EN.
		Read 0	ADMA2 supported
		Read 1	ADMA2 not supported
18	Reserved	0	Reserved bit field. Do not write any value.
17-16	MBL		Maximum block length. This value indicates the maximum block size that the host driver can read and write to the buffer in the host controller.
			The host controller supports 512 bytes and 1024 bytes block transfers.
		Read 0	512 bytes
		Read 1	1024 bytes
		Read 2	2048 bytes
15-14	Reserved	0	Reserved bit field. Do not write any value.
13-8	BCF		Base clock frequency for clock provided to the card.
		Read 0	The value indicating the base (maximum) frequency for the output clock provided to the card is system dependent and is not available in this register. Get the information via another method. See the *Power, Reset, and Clock Management* chapter for more information on the value of FUNC_96M_CLK clock signal.
7	TCU		Timeout clock unit. This bit shows the unit of base clock frequency used to detect Data Timeout Error (SD_STAT[20] DTO bit).
		Read 0	kHz
		Read 1	MHz
6	Reserved	0	Reserved. This bit is initialized to zero, and writes to it are ignored.
5-0	TCF		Timeout clock frequency. The timeout clock frequency is used to detect Data Timeout Error (SD_STAT[20] DTO bit).
		Read 0	The timeout clock frequency depends on the frequency of the clock provided to the card. The value of the timeout clock frequency is not available in this register.

Copyright © 2011, Texas Instruments Incorporated

18.4.24 Maximum Current Capabilities Register (SD_CUR_CAPA)

This register indicates the maximum current capability for each voltage. The value is meaningful if the voltage support is set in the capabilities register (SD_CAPA).

Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initialization.

This register is only reinitialized by a hard reset (via mmc_RESET signal). The maximum current capabilities register (SD_CUR_CAPA) is shown in Figure 18-60 and described in Table 18-43.

Figure 18-60. Maximum Current Capabilities Register (SD_CUR_CAPA)

31 24	23 16	15 8	7 0

18.4.25 Force Event Register for Error Interrupt Status (SD_FE)

The Force Event register is not a physically implemented register. Rather, it is an address at which the Error Interrupt Status register can be written. The effect of a write to this address will be reflected in the Error Interrupt Status Register, if corresponding bit of the Error Interrupt Status Enable Register is set.

The force event register (SD_FE) is shown in Figure 18-61 and described in Table 18-44.

Figure 18-61. Interrupt Signal Enable Register (SD_ISE)

18.4.26 ADMA Error Status Register (SD_ADMAES)

When an ADMA Error Interrupt has occurred, the ADMA Error States field in this register holds the ADMA state and the ADMA System Address Register holds the address around the error descriptor. For recovering the error, the Host Driver requires the ADMA state to identify the error descriptor address as follows:

- ST_STOP: Previous location set in the ADMA System Address register is the error descriptor address.
- ST_FDS: Current location set in the ADMA System Address register is the error descriptor address.
- ST_CADR: This sate is never set because do not generate ADMA error in this state.
- ST_TFR: Previous location set in the ADMA System Address register is the error descriptor address.

In the case of a write operation, the Host Driver should use ACMD22 to get the number of written block rather than using this information, since unwritten data may exist in the Host Controller. The Host Controller generates the ADMA Error Interrupt when it detects invalid descriptor data (Valid = 0) at the ST_FDS state. In this case, ADMA Error State indicates that an error occurs at ST_FDS state. The Host Driver may find that the Valid bit is not set in the error descriptor.

The ADMA error status register (SD_BLK) is shown in Figure 18-62 and described in Table 18-45.

Figure 18-62. ADMA Error Status Register (SD_ADMAES)

31	3	2	1	0
Reserved		LME	AES	
R-0		W-0	R/W-0	

LEGENDR/W = Read/Write; R = Read only; -*n* = value after reset

Table 18-45. ADMA Error Status Register (SD_ADMAES) Field Descriptions

Bit	Field	Value	Description
31-3	Reserved	0	Reserved bit field. Do not write any value.
2	LME		ADMA Length Mismatch Error: • While Block Count Enable is being set, the total data length specified by the Descriptor table is different from that specified by the Block Count and Block Length. • Total data length cannot be divided by the block length.
		0	No error
		1	Error
1-0	AES		ADMA Error State. This field indicates the state of ADMA when an error occurred during an ADMA data transfer. This field never indicates "10" because ADMA never stops in this state.
		Read 0	ST_STOP (Stop DMA). Contents of the SYS_SDR register
		Write 1h	ST_STOP (Stop DMA). Points to the error descriptor.
		Read 2h	Never set this state. (Not used)
		Write 3h	ST_TFR (Transfer Data). Points to the 'next' of the error descriptor.

Copyright © 2011, Texas Instruments Incorporated

18.4.27 ADMA System Address Low Bits Register (SD_ADMASAL)

This register holds the byte address of the executing command of the Descriptor table. The 32-bit Address Descriptor uses the lower 32 bits of this register. At the start of ADMA, the Host Driver shall set the start address of the Descriptor table.

The ADMA System address low bits register (SD_ADMASAL) is shown in Figure 18-63 and described in Table 18-46.

Figure 18-63. ADMA System Address Low Bits (SD_ADMASAL)

31	0
ADMA_A32B	
R/W-0	

LEGENDR/W = Read/Write; R = Read only; -*n* = value after reset

Table 18-46. ADMA System Address Low Bits (SD_ADMASAL) Field Descriptions

Bit	Field	Value	Description
31-0	ADMA_A32B		The ADMA increments this register address, which points to the next line, whenever fetching a Descriptor line. When the ADMA Error Interrupt is generated, this register holds the valid Descriptor address depending on the ADMA state. The Host Driver shall program the Descriptor Table on a 32-bit boundary and set the 32-bit boundary address to this register. ADMA2 ignores the lower 2 bits of this register and assumes it to be 00b.

18.4.28 ADMA System Address High Bits Register (SD_ADMASAH)

The ADMA System address high bits register (SD_ADMASAH) is shown in Figure 18-63 and described in Table 18-46.

Figure 18-64. ADMA System Address High Bits Register (SD_ADMASAH)

31	0

18.4.29 Versions Register (SD_REV)

This register contains the hard coded RTL vendor revision number, the version number of SD specification compliancy and a slot status bit.

- SD_REV[31:16] = Host Controller Version
- SD_REV[15:0] = Slot Interrupt Status

The versions register (SD_REV) is shown in Figure 18-65 and described in Table 18-48.

Figure 18-65. Versions Register (SD_REV)

31 24	23 16	15 1	0
VREV	SREV	Reserved	SIS
R-x	R-0	R-0	R-0

LEGENDR/W = Read/Write; R = Read only; *-n* = value after reset

Table 18-48. Versions Register (SD_REV) Field Descriptions

Bit	Field	Value	Description
31-24	VREV	0	Vendor Version Number. Bits [7:4] is the major revision, bits [3:0] is the minor revision. Examples: 10h for 1.0 21h for 2.1
23-16	SREV	Read 0	Specification Version Number. This status indicates the Standard SD Host Controller Specification Version. The upper and lower 4-bits indicate the version. SD Host Specification Version 1.0
15-1	Reserved	0	Reserved bit field. Do not write any value.
0	SIS		Slot Interrupt Status. This status bit indicates the inverted state of interrupt signal for the module. By a power on reset or by setting a software reset for all (SD_SYSCTL[24] SRA), the interrupt signal shall be deasserted and this status shall read 0.

Universal Asynchronous Receiver/Transmitter (UART)

This chapter describes the UART of the device.

Topic **Page**

19.1 Introduction 3966
19.2 Integration 3968
19.3 Functional Description 3972
19.4 UART/IrDA/CIR Basic Programming Model 4015
19.5 UART Registers 4024

Copyright © 2011, Texas Instruments Incorporated

19.1 Introduction

19.1.1 UART Mode Features

The general features of the UART/IrDA module when operating in UART mode are:

- 16C750 compatibility
- Baud rate from 300 bps up to 3.6864 Mbps
- Auto-baud between 1200 bps and 115.2 Kbps
- Software/Hardware flow control
  - Programmable Xon/Xoff characters
  - Programmable Auto-RTS and Auto CTS
- Programmable serial interface characteristics
  - 5, 6, 7, or 8-bit characters
  - Even, odd, mark (always 1), space (always 0), or no parity (non-parity bit frame) bit generation and detection
  - 1, 1.5, or 2 stop bit generation
- False start bit detection
- Line break generation and detection
- Modem control functions (CTS, RTS, DSR, DTR, RI, and DCD)
- Fully prioritized interrupt system controls
- Internal test and loopback capabilities

19.1.2 IrDA Mode Features

The general features of the UART/IrDA when operating in IrDA mode are:

- Support of IrDA 1.4 slow infrared (SIR), medium infrared (MIR) and fast infrared (FIR) communications (very fast infrared (VFIR) is not supported)
- Frame formatting: addition of variable xBOF characters and EOF characters
- Uplink/downlink CRC generation/detection
- Asynchronous transparency (automatic insertion of break character)
- 8-entry status FIFO (with selectable trigger levels) available to monitor frame length and frame errors
- Framing error, cyclic redundancy check (CRC) error, illegal symbol (FIR), abort pattern (SIR, MIR) detection

19.1.3 CIR Mode Features

The general features of the UART/IrDA when operating in CIR mode are:

- Support of consumer infrared (CIR) for remote control applications
- Transmit and receive
- Free data format (supports any remote control private standards)
- Selectable bit rate
- Configurable carrier frequency
- 1/2, 5/12, 1/3 or 1/4 carrier duty cycle

19.1.4 Unsupported UART Features

The following UART/IrDA module features are not supported in this device.

Copyright © 2011, Texas Instruments Incorporated

Table 19-1. Unsupported UART Features

Feature	Reason
Full modem control on UART0	DCD, DSR, DTR, RI not pinned-out
Full modem control on UART2-5	DCD, DSR, DTR, RI not pinned-out
Device wake-up on UART1-5	Wake-up not supported - no SWake connection

Copyright © 2011, Texas Instruments Incorporated

19.2 Integration

This device contains 6 instantiations of the UART/IrDA (UARTIRDAOCP) peripheral. There are six UART modules called UART0 – UART5. UART0 provides wakeup capability. Only UART 1 provides full modem control signals. All UARTs support IrDA and CIR modes and RTS/CTS flow control (subject to pin muxing configuration). Figure 19-1 shows an example of system connectivity using UART communication with hardware handshake.

Figure 19-1. UART/IrDA Module — UART Application

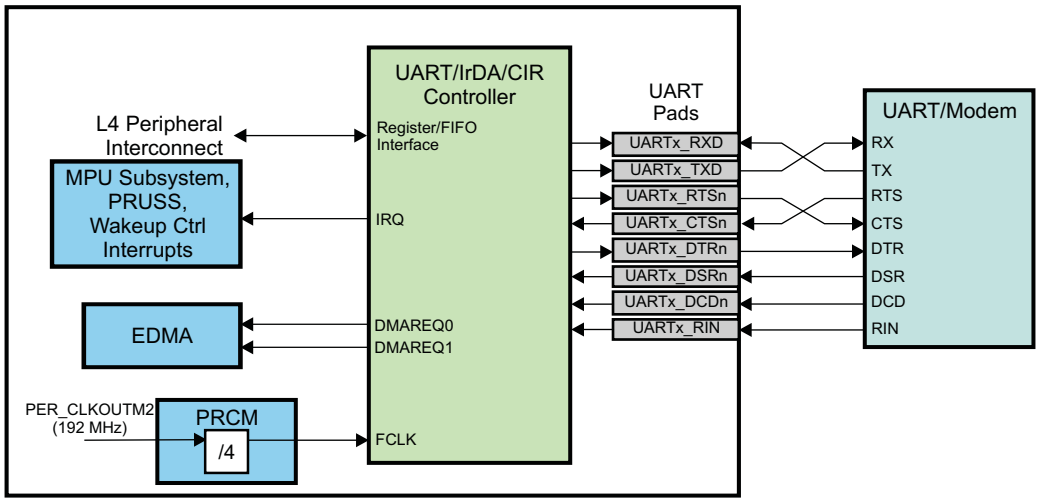

Figure 19-2 shows an example of system connectivity using infrared communication with remote control (consumer infrared).

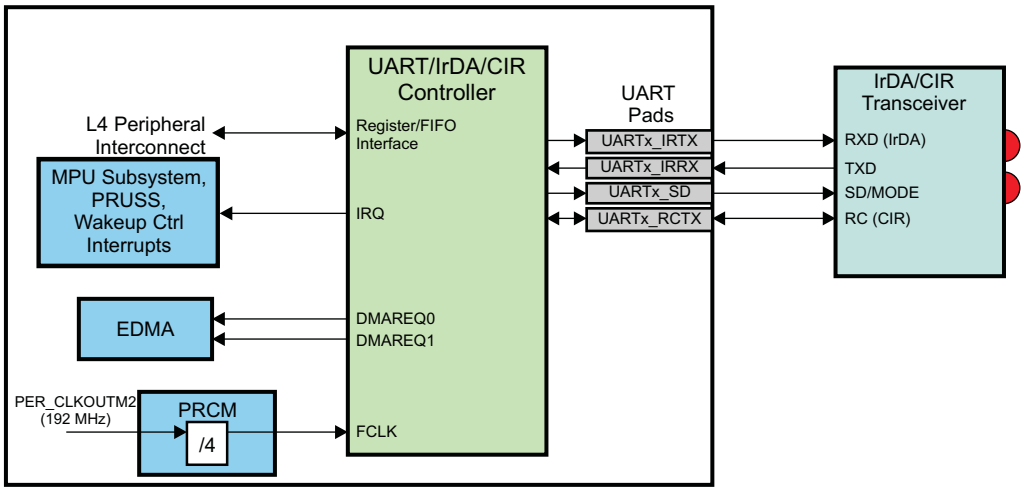
Figure 19-2. UART/IrDA Module — IrDA/CIR Application



19.2.1 UART Connectivity Attributes

The general connectivity attributes for each of the UART modules are shown in Table 19-2 and Table 19-3.

Table 19-2. UART0 Connectivity Attributes

Attributes	Type
Power Domain	Wake-Up Domain
Clock Domain	PD_WKUP_L4_WKUP_GCLK (OCP) PD_WKUP_UART0_GFCLK (Func)

Table 19-2. UART0 Connectivity Attributes (continued)

Attributes	Type
Reset Signals	WKUP_DOM_RST_N
Idle/Wakeup Signals	Smart Idle / Wakeup
Interrupt Requests	1 interrupt to MPU Subsystem (UART0INT), PRUSS (nirq) and WakeM3
DMA Requests	2 DMA requests to EDMA (TX – UTXEVT0, RX – URXEVT0)
Physical Address	L4 Wakeup slave port

Table 19-3. UART1–5 Connectivity Attributes

Attributes	Type
Power Domain	Peripheral Domain
Clock Domain	PD_PER_L4LS_GCLK (OCP) PD_PER_UART_GFCLK (Func)
Reset Signals	PER_DOM_RST_N
Idle/Wakeup Signals	Smart Idle
Interrupt Requests	UART1-2 1 interrupt per instance to MPU Subsystem (UART1INT, UART2INT) and PRUSS (nirq) UART3-5 1 interrupt per instance to only MPU Subsystem (UART3INT, UART4INT, UART5INT)
DMA Requests	2 DMA requests per instance to EDMA (TX – UTXEVTx, RX – URXEVTx)
Physical Address	L4 Peripheral slave port

19.2.2 UART Clock and Reset Management

The UART modules use separate functional and bus interface clocks.

Table 19-4. UART0 Clock Signals

Clock Signal	Max Freq	Reference / Source	Comments
CLK			
Interface clock	100 MHz	CORE_CLKOUTM4 / 2	pd_wkup_l4_wkup_gclk
From PRCM			
FCLK			
Functional clock	48 MHz	PER_CLKOUTM2 / 4	pd_wkup_uart0_gfclk
from PRCM			

Table 19-5. UART1–5 Clock Signals

Clock Signal	Max Freq	Reference / Source	Comments
CLK Interface clock	100 MHz	CORE_CLKOUTM4 / 2	pd_per_l4ls_gclk From PRCM
FCLK Functional clock	48 MHz	PER_CLKOUTM2 / 4	pd_per_uart_gfclk From PRCM

For UART operation, the functional clock is used to produce a baud rate up to 3.6M bits/s. Table 19-6 lists the supported baud rates, the requested divider, and the corresponding error versus the standard baud rate.

19.2.3 UART Pin List

The UART interface pins are listed in Table 19-8. Pin functionality depends on the selected operating mode of the module.

Table 19-8. UART Pin List

Pin	Type	Description
UARTx_RXD / IRRX / RCRX	I	UART / IrDA / CIR Receive Data
UARTx_TXD / IRTX / RCTX	OZ	UART / IrDA / CIR Transmit Data
UARTx_RTSn / SD	OZ	UART Request to Send / IrDA Mode
UARTx_CTSn	I	UART Clear to Send
UARTx_DTRn(1)	OZ	UART Data Terminal Ready
UARTx_DSRn(1)	I	UART Data Set Ready
UARTx_DCDn(1)	I	UART Data Carrier Detect
UARTx_RIN(1)	1	UART Ring Indicator

(1) UART1 only

The UART module can operate in three different modes based on the MODE_SELECT bits. The signal muxing based on these mode bits is shown in Table 19-9.

Table 19-9. UART Muxing Control

UARTx_TXD / IRTX / RCTX Function	UARTx_RXD / IRRX / RCRX Function	UARTx_RTSn / SD Function	UARTx_CTSn Function	Mode
TXD	RXD	RTSn	CTSn	UART
IRTX	IRRX	SD	not used	IrDA (SIR, MIR, FIR)
RCTX	RCRX	SD	not used	CIR

19.3 Functional Description

19.3.1 Block Diagram

The UART/IrDA/CIR module can be divided into three main blocks:

- FIFO management
- Mode selection
- Protocol formatting

FIFO management is common to all functions and enables the transmission and reception of data from the host processor point of view.

There are two modes:

- Function mode: Routes the data to the chosen function (UART, IrDA, or CIR) and enables the mechanism corresponding to the chosen function
- Register mode: Enables conditional access to registers

For more information about mode configuration, see Section 19.3.7, *Mode Selection*.

Protocol formatting has three subcategories:

- Clock generation: The 48-MHz input clock generates all necessary clocks.
- Data formatting: Each function uses its own state-machine that is responsible for the transition between FIFO data and frame data associated with it.
- Interrupt management: Different interrupt types are generated depending on the chosen function:
  - UART mode interrupts: Seven interrupts prioritized in six different levels
  - IrDA mode interrupts: Eight interrupts. The interrupt line is activated when any interrupt is generated (there is no priority).
  - CIR mode interrupts: A subset of existing IrDA mode interrupts is used.

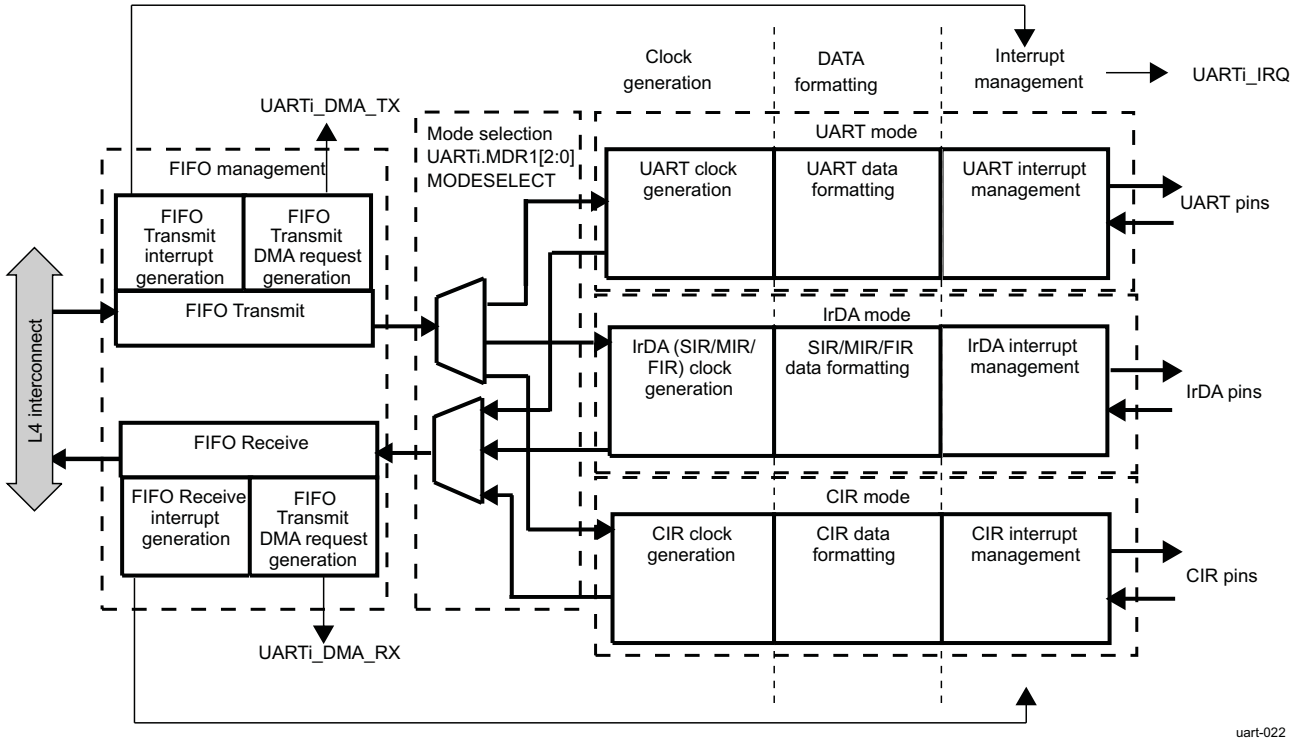
  In each mode, when an interrupt is generated, the UART_IIR register indicates the interrupt type.

In parallel with these functional blocks, a power-saving strategy exists for each function.

Figure 19-3 is the UART/IrDA/CIR block diagram.

Copyright © 2011, Texas Instruments Incorporated

Figure 19-3. UART/IrDA/CIR Functional Specification Block Diagram



19.3.2 Clock Configuration

Each UART uses a 48-MHz functional clock for its logic and to generate external interface signals. Each UART uses an interface clock for register accesses. The PRCM module generates and controls all these clocks (for more information, see , *Clock Domain Module Attributes*, in Chapter 8, *Power, Reset, and Clock Management*).

The idle and wake-up processes use a handshake protocol between the PRCM and the UART (for a description of the protocol, see , *Module-Level Clock Managment*, in Chapter 8, *Power, Reset, and Clock Management*). The UARTi.UART_SYSC[4:3] IDLEMODE bit field controls UART idle mode.

19.3.3 Software Reset

The UARTi.UART_SYSC[1] SOFTRESET bit controls the software reset; setting this bit to 1 triggers a software reset functionally equivalent to hardware reset.

19.3.4 Power Management

19.3.4.1 UART Mode Power Management

19.3.4.1.1 Module Power Saving

In UART modes, sleep mode is enabled by setting the UARTi.UART_IER[4] SLEEP_MODE bit to 1 (when the UARTi.UART_EFR[4] ENHANCED_EN bit is set to 1).

Sleep mode is entered when all the following conditions exist:

- The serial data input line, uarti_rx, is idle.
- The TX FIFO and TX shift register are empty.
- The RX FIFO is empty.
- The only pending interrupts are THR interrupts.

Copyright © 2011, Texas Instruments Incorporated

Sleep mode is a good way to lower UART power consumption, but this state can be achieved only when the UART is set to modem mode. Therefore, even if the UART has no key role functionally, it must be initialized in a functional mode to take advantage of sleep mode.

In sleep mode, the module clock and baud rate clock are stopped internally. Because most registers are clocked by these clocks, this greatly reduces power consumption. The module wakes up when a change is detected on the uarti_rx line, when data is written to the TX FIFO, and when there is a change in the state of the modem input pins.

An interrupt can be generated on a wake-up event by setting the UARTi.UART_SCR[4] RX_CTS_WU_EN bit to 1. To understand how to manage the interrupt, see Section 19.3.5.2, *Wake-Up Interrupt*.

NOTE: There must be no writing to the divisor latches, UARTi.UART_DLL and UARTi.UART_DLH, to set the baud clock (BCLK) while in sleep mode. It is advisable to disable sleep mode using the UARTi.UART_IER[4] SLEEP_MODE bit before writing to the UARTi.UART_DLL register or the UARTi.UART_DLH register.

19.3.4.1.2 System Power Saving

Sleep and auto-idle modes are embedded power-saving features. Power-reduction techniques can be applied at the system level by shutting down certain internal clock and power domains of the device.

The UART supports an idle req/idle ack handshaking protocol used at the system level to shut down the UART clocks in a clean and controlled manner and to switch the UART from interrupt-generation mode to wake-up generation mode for unmasked events (see the UARTi.UART_SYSC[2] ENAWAKEUP bit and the UARTi.UART_WER register).

For more information, see , *Module Level Clock Managment*, in Chapter 8, *Power, Reset, and Clock Management*.

19.3.4.2 IrDA/CIR Mode Power Management

19.3.4.2.1 Module Power Saving

In IrDA/CIR modes, sleep mode is enabled by setting the UARTi.MDR[3] IR_SLEEP bit to 1.

Sleep mode is entered when all the following conditions exist:

- The serial data input line, uarti.rx_irrx, is idle.
- The TX FIFO and TX shift register are empty.
- The RX FIFO is empty.
- No interrupts are pending except THR interrupts.

The module wakes up when a change is detected on the uarti_rx_irrx line or when data is written to the TX FIFO.

19.3.4.2.2 System Power Saving

System power saving for the IrDA/CIR mode has the same function as for the UART mode (see Section 19.3.4.1.2, *System Power Saving*).

19.3.4.3 Local Power Management

Table 19-10 describes power-management features available for the UART.

NOTE: For information about source clock gating and sleep/wake-up transitions description, see , *Module-Level Clock Managment*, in Chapter 8, *Power, Reset, and Clock Management*.

Copyright © 2011, Texas Instruments Incorporated

Table 19-10. Local Power-Management Features

Feature	Registers	Description
Clock autogating	UART_SYSC[0] AUTOIDLE	This bit allows local power optimization in the module by gating the UARTi_ICLK clock on interface activity or gating the UARTi_FCLK clock on internal activity.
Slave idle modes	UART_SYSC[4:3] IDLEMODE	Force-idle, no-idle, smart-idle, and smart-idle wakeup-capable modes are available
Clock activity	N/A	Feature not available
Master standby modes	N/A	Feature not available
Global wake-up enable	UART_SYSC[2] ENAWAKEUP	This bit enables the wake-up feature at module level.
Wake-Up sources enable	N/A	Feature not available

19.3.5 Interrupt Requests

The UART IrDA CIR module generates interrupts. All interrupts can be enabled/disabled by writing to the appropriate bit in the interrupt enable register (IER). The interrupt status of the device can be checked at any time by reading the interrupt identification register (IIR). The UART, IrDA, and CIR modes have different interrupts in the UART IrDA CIR module and therefore have different IER and IIR mappings according to the selected mode.

19.3.5.1 UART Mode Interrupt Management

19.3.5.1.1 UART Interrupts

UART mode includes seven possible interrupts prioritized to six levels.

When an interrupt is generated, the interrupt identification register (UARTi.UART_IIR) sets the UARTi.UART_IIR[0] IT_PENDING bit to 0 to indicate that an interrupt is pending, and indicates the type of interrupt through the UARTi.UART_IIR[5:1] bit field. Table 19-11 summarizes the interrupt control functions.

Table 19-11. UART Mode Interrupts

UART_IIR[5:0]	Priority Level	Interrupt Type	Interrupt Source	Interrupt Reset Method
000001	None	None	None	None
000110	1	Receiver line status	OE, FE, PE, or BI errors occur in characters in the RX FIFO.	FE, PE, BI: Read the UART_RHR register. OE: Read the UART_LSR register.
001100	2	RX time-out	Stale data in RX FIFO	Read the UART_RHR register.
000100	2	RHR interrupt	DRDY (data ready) (FIFO disable)	Read the UART_RHR register until the interrupt condition disappears.
			RX FIFO above trigger level (FIFO enable)	
000010	3	THR interrupt	TFE (UART_THR empty) (FIFO disable)	Write to the UART_THR until the interrupt condition disappears.
			TX FIFO below trigger level (FIFO enable)	
000000	4	Modem status	See the UART_MSR register.	Read the UART_MSR register.
010000	5	XOFF interrupt/special character interrupt	Receive XOFF characters/special character	Receive XON character(s), if XOFF interrupt/read of the UART_IIR register, if special character interrupt.
100000	6	CTS, RTS, DSR	RTS pin or CTS pin or DSR change state from active (low) to inactive (high).	Read the UART_IIR register.

Copyright © 2011, Texas Instruments Incorporated

For the receiver-line status interrupt, the RX_FIFO_STS bit (UARTi.UART_LSR[7]) generates the interrupt.

For the XOFF interrupt, if an XOFF flow character detection caused the interrupt, the interrupt is cleared by an XON flow character detection. If special character detection caused the interrupt, the interrupt is cleared by a read of the UARTi.UART_IIR register.

19.3.5.2 Wake-Up Interrupt

Wake-up interrupt is a special interrupt that works differently from other interrupts. This interrupt is enabled when the UARTi.UART_SCR[4] RXCTSDSRWAKEUPENABLE bit is set to 1. The UARTi.UART_IIR register is not modified when this occurs; the UARTi.UART_SSR[1] RXCTSDSRWAKEUPSTS bit must be checked to detect a wake-up event.

When a wake-up interrupt occurs, it can be cleared only by resetting the UARTi.UART_SCR[4] RXCTSDSRWAKEUPENABLE bit. This bit must be re-enabled (set to 1) after the current wake-up interrupt event is processed to detect the next incoming wake-up event.

A wake-up interrupt can also occur if the WER[7] TXWAKEUPEN bit is set to 1 and one of the following occurs:

- THR interrupt occurred if it is enabled (omitted if TX DMA request is enabled).
- TX DMA request occurred if it is enabled.
- TX_STATUS_IT occurred if it is enabled (only IrDA and CIR modes). Cannot be used with THR interrupt.

CAUTION

Wake-Up interface implementation in IrDA mode is based on the UARTi_SIDLEACK low-to-high transition instead of the UARTi_SIDLEACK state.

This does not ensure wake-up event generation as expected when configured in smart-idle mode, and the system wakes up for a short period.

19.3.5.3 IrDA Mode Interrupt Management

19.3.5.3.1 IrDA Interrupts

The IrDA function generates interrupts. All interrupts can be enabled and disabled by writing to the appropriate bit in the interrupt enable register (UARTi.UART_IER). The interrupt status of the device can be checked by reading the interrupt identification register (UARTi.UART_IIR).

UART, IrDA, and CIR modes have different interrupts in the UART/IrDA/CIR module and, therefore, different UARTi.UART_IER and UARTi.UART_IIR mappings, depending on the selected mode.

IrDA modes have eight possible interrupts (see Table 19-12). The interrupt line is activated when any interrupt is generated (there is no priority).

Table 19-12. IrDA Mode Interrupts

UART_IIR Bit	Interrupt Type	Interrupt Source	Interrupt Reset Method
0	RHR interrupt	DRDY (data ready) (FIFO disable) RX FIFO above trigger level (FIFO enable)	Read the UART_RHR register until the interrupt condition disappears.
1	THR interrupt	TFE (UART_THR empty) (FIFO disable) TX FIFO below trigger level (FIFO enable)	Write to the UART_THR until the interrupt condition disappears.

Copyright © 2011, Texas Instruments Incorporated

Table 19-12. IrDA Mode Interrupts (continued)

UART_IIR Bit	Interrupt Type	Interrupt Source	Interrupt Reset Method
2	Last byte in RX FIFO	Last byte of frame in RX FIFO is available to be read at the RHR port.	Read the UART_RHR register.
3	RX overrun	Write to the UART_RHR register when the RX FIFO is full.	Read UART_RESUME register.
4	Status FIFO interrupt	Status FIFO triggers level reached.	Read STATUS FIFO.
5	TX status	1. UART_THR empty before EOF sent. Last bit of transmission of the IrDA frame occurred, but with an underrun error. OR 2. Transmission of the last bit of the IrDA frame completed successfully.	1. Read the UART_RESUME register. OR 2. Read the UART_IIR register.
6	Receiver line status interrupt	CRC, ABORT, or frame-length error is written into the STATUS FIFO.	Read the STATUS FIFO (read until empty - maximum of eight reads required).
7	Received EOF	Received end-of-frame	Read the UART_IIR register.

19.3.5.4 CIR Mode Interrupt Management

19.3.5.4.1 CIR Interrupts

The CIR function generates interrupts that can be enabled and disabled by writing to the appropriate bit in the interrupt enable register (UARTi.UART_IER). The interrupt status of the device can be checked by reading the interrupt identification register (UARTi.UART_IIR).

UART, IrDA, and CIR modes have different interrupts in the UART/IrDA/CIR module and, therefore, different UARTi.UART_IER and UARTi.UART_IIR mappings, depending on the selected mode.

Table 19-13 lists the interrupt modes to be maintained. In CIR mode, the sole purpose of the UARTi.UART_IIR[5] bit is to indicate that the last bit of infrared data was passed to the uart_cts_rctx pin.

Table 19-13. CIR Mode Interrupts

UART_IIR Bit Number	Interrupt Type	Interrupt Source	Interrupt Reset Method
0	RHR interrupt	DRDY (data ready) (FIFO disable) RX FIFO above trigger level (FIFO enable)	Read UART_RHR until interrupt condition disappears.
1	THR interrupt	TFE (UART_THR empty) (FIFO disable) TX FIFO below trigger level (FIFO enable)	Write to the UART_THR register until the interrupt condition disappears.
2	RX_STOP_IT	Receive stop interrupt (depending on value set in the BOF Length Register (UART_EBLR).	Read IIR
3	RX overrun	Write to RHR when RX FIFO is full.	Read RESUME register.
4	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode
5	TX status	Transmission of the last bit of the frame is complete successfully.	Read the UART_IIR register.
6	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode
7	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode

Copyright © 2011, Texas Instruments Incorporated

19.3.6 FIFO Management

The FIFO is accessed by reading and writing the UARTi.UART_RHR and UARTi.UART_THR registers. Parameters are controlled using the FIFO control register (UARTi.UART_FCR) and supplementary control register (UARTi.UART_SCR). Reading the UARTi.UART_SSR[0] TX_FIFO_FULL bit at 1 means the FIFO is full.

The UARTi.UART_TLR register controls the FIFO trigger level, which enables DMA and interrupt generation. After reset, transmit (TX) and receive (RX) FIFOs are disabled; thus, the trigger level is the default value of 1 byte. Figure 19-4 shows the FIFO management registers.

NOTE: Data in the UARTi.UART_RHR register is not overwritten when an overflow occurs.

NOTE: The UARTi.UART_SFLSR, UARTi.UART_SFREGL, and UARTi.UART_SFREGH status registers are used in IrDA mode only. For use, see Section 19.3.8.2.6, *IrDA Data Formatting*.

Figure 19-4. FIFO Management Registers

19.3.6.1 FIFO Trigger

19.3.6.1.1 Transmit FIFO Trigger

Table 19-14 lists the TX FIFO trigger level settings.

Table 19-14. TX FIFO Trigger Level Setting Summary

UART_SCR[6]	UART_TLR[3:0]	TX FIFO Trigger Level
0	= 0x0	Defined by the UARTi.UART_FCR[5:4] TX_FIFO_TRIG bit field (8,16, 32, or 56 spaces)
0	!= 0x0	Defined by the UARTi.UART_TLR[3:0] TX_FIFO_TRIG_DMA bit field (from 4 to 60 spaces with a granularity of 4 spaces)
1	Value	Defined by the concatenated value of TX_FIFO_TRIG_DMA and TX_FIFO_TRIG (from 1 to 63 spaces with a granularity of 1 space) **Note:** The combination of TX_FIFO_TRIG_DMA = 0x0 and TX_FIFO_TRIG = 0x0 (all zeros) is not supported (minimum of one space required). All zeros result in unpredictable behavior.

19.3.6.1.2 Receive FIFO Trigger

Table 19-15 lists the RX FIFO trigger level settings.

Table 19-15. RX FIFO Trigger Level Setting Summary

UART_SCR[7]	UART_TLR[7:4]	RX FIFO Trigger Level
0	= 0x0	Defined by the UARTi.UART_FCR[7:6] RX_FIFO_TRIG bit field (8,16, 56, or 60 characters)
0	!= 0x0	Defined by the UARTi.UART_TLR[7:4] RX_FIFO_TRIG_DMA bit field (from 4 to 60 characters with a granularity of 4 characters)
1	Value	Defined by the concatenated value of RX_FIFO_TRIG_DMA and RX_FIFO_TRIG (from 1 to 63 characters with a granularity of 1 character) **Note:** The combination of RX_FIFO_TRIG_DMA = 0x0 and RX_FIFO_TRIG = 0x0 (all zeros) is not supported (minimum of one character required). All zeros result in unpredictable behavior.

The receive threshold is programmed using the UARTi.UART_TCR[7:4] RX_FIFO_TRIG_START and UARTi.UART_TCR[3:0] RX_FIFO_TRIG_HALT bit fields:

- Trigger levels from 0 to 60 bytes are available with a granularity of 4 (trigger level = 4 x [4-bit register value]).
- To ensure correct device operation, ensure that RX_FIFO_TRIG_HALT RX_FIFO_TRIG when auto-RTS is enabled.

  Delay = [4 + 16 x (1 + CHAR_LENGTH + Parity + Stop 0.5)] x Baud_rate + 4 x FCLK

  NOTE: The RTS signal is deasserted after the UART module receives the data over RX_FIFO_TRIG_HALT. Delay means how long the UART module takes to deassert the RTS signal after reaching RX_FIFO_TRIG_HALT.

- In FIFO interrupt mode with flow control, ensure that the trigger level to HALT transmission is greater than or equal to the RX FIFO trigger level (the UARTi.UART_TCR[7:4] RX_FIFO_TRIG_START bit field or the UARTi.UART_FCR[7:6] RX_FIFO_TRIG bit field); otherwise, FIFO operation stalls. In FIFO DMA mode with flow control, this concept does not exist, because a DMA request is sent when a byte is received.

19.3.6.2 FIFO Interrupt Mode

In FIFO interrupt mode (the FIFO control register UARTi.UART_FCR[0] FIFO_EN bit is set to 1 and

Copyright © 2011, Texas Instruments Incorporated

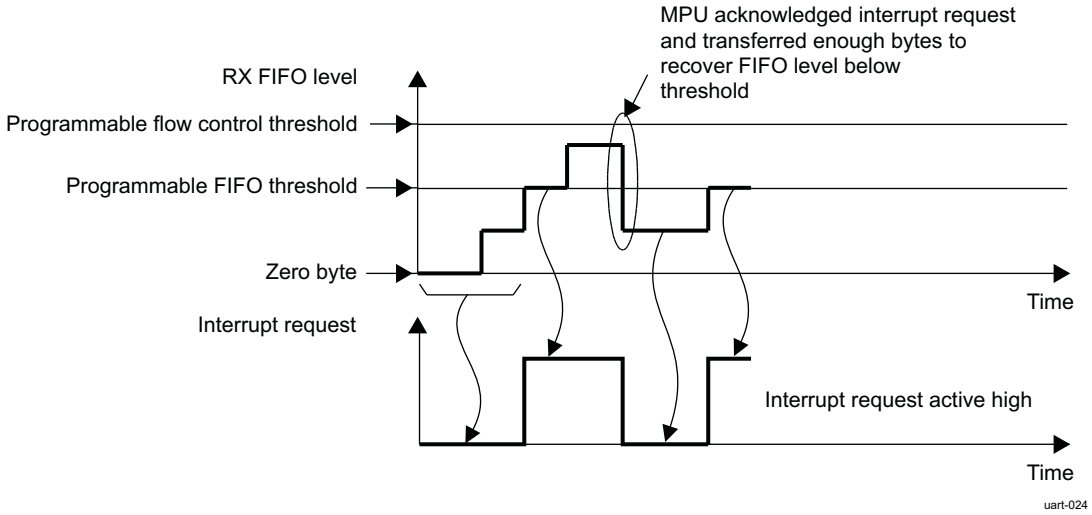
relevant interrupts are enabled by the UARTi.UART_IER register), an interrupt signal informs the processor of the status of the receiver and transmitter. These interrupts are raised when the RX/TX FIFO threshold (the UARTi.UART_TLR[7:4] RX_FIFO_TRIG_DMA and UARTi.UART_TLR[3:0] TX_FIFO_TRIG_DMA bit fields or the UARTi.UART_FCR[7:6] RX_FIFO_TRIG and UARTi.UART_FCR[5:4] TX_FIFO_TRIG bit fields, respectively) is reached.

The interrupt signals instruct the MPU to transfer data to the destination (from the UART in receive mode and/or from any source to the UART FIFO in transmit mode).

When UART flow control is enabled with interrupt capabilities, the UART flow control FIFO threshold (the UARTi.UART_TCR[3:0] RX_FIFO_TRIG_HALT bit field) must be greater than or equal to the RX FIFO threshold.

Figure 19-5 shows the generation of the RX FIFO interrupt request.

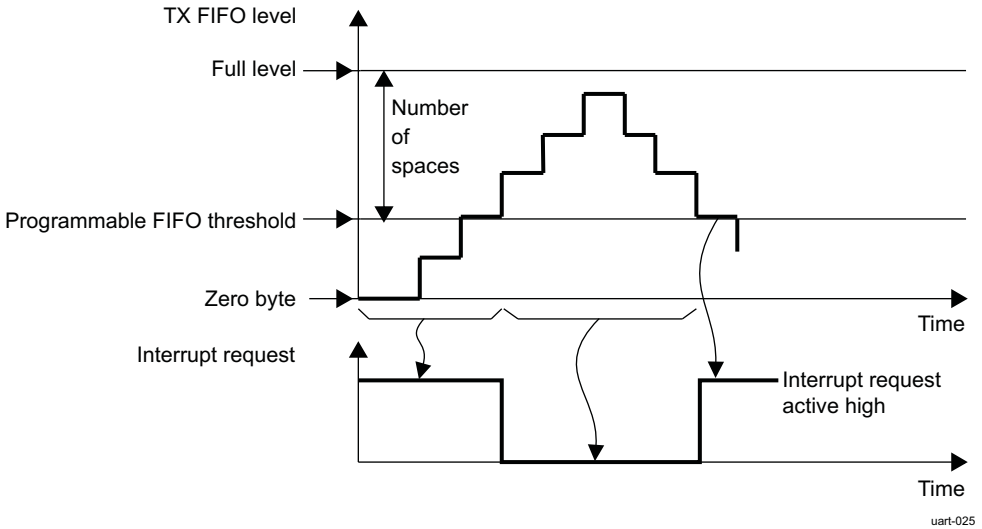
Figure 19-5. RX FIFO Interrupt Request Generation



In receive mode, no interrupt is generated until the RX FIFO reaches its threshold. Once low, the interrupt can be deasserted only when the MPU has handled enough bytes to put the FIFO level below threshold. The flow control threshold is set at a higher value than the FIFO threshold.

Figure 19-6 shows the generation of the TX FIFO interrupt request.

Figure 19-6. TX FIFO Interrupt Request Generation



Copyright © 2011, Texas Instruments Incorporated

In transmit mode, an interrupt request is automatically asserted when the TX FIFO is empty. This request is deasserted when the TX FIFO crosses the threshold level. The interrupt line is deasserted until a sufficient number of elements is transmitted to go below the TX FIFO threshold.

19.3.6.3 FIFO Polled Mode Operation

In FIFO polled mode (the UARTi.UART_FCR[0] FIFO_EN bit is set to 0 and the relevant interrupts are disabled by the UARTi.UART_IER register), the status of the receiver and transmitter can be checked by polling the line status register (UARTi.UART_LSR).

This mode is an alternative to the FIFO interrupt mode of operation in which the status of the receiver and transmitter is automatically determined by sending interrupts to the MPU.

19.3.6.4 FIFO DMA Mode Operation

Although DMA operation includes four modes (DMA modes 0 through 3), the information in assumes that mode 1 is used. (Mode 2 and mode 3 are legacy modes that use only one DMA request for each module.)

In mode 2, the remaining DMA request is used for RX. In mode 3, the remaining DMA request is used for TX.

DMA requests in mode 2 and mode 3 use the following signals:

- S_DMA_48
- S_DMA_50
- S_DMA_52/D_DMA_10
- S_DMA_54

The following signals are not used by the module in mode 2 and mode 3:

- S_DMA_49
- S_DMA_51
- S_DMA_53/D_DMA_11
- S_DMA_55

These signals can be selected as follows:

- When the UARTi.UART_SCR[0] DMA_MODE_CTL bit is set to 0, setting the UARTi.UART_FCR[3] DMA_MODE_CTL bit to 0 enables DMA mode 0. Setting the DMA_MODE_CTL bit to 1 enables DMA mode 1.
- When the DMA_MODE_CTL bit is set to 1, the UARTi.UART_FCR[2:1] DMA_MODE_2 bit field determines DMA mode 0 to mode 3 based on the supplementary control register (UART_SCR) description.

For example:

- If no DMA operation is desired, set the DMA_MODE_CTL bit to 1 and the DMA_MODE_2 bit field to 0x0. (The DMA_MODE bit is discarded.)
- If DMA mode 1 is desired, set the DMA_MODE_CTL bit to 0 and the DMA_MODE bit to 1, or set the DMA_MODE_CTL bit to 1 and the DMA_MODE_2 bit field to 01. (The DMA_MODE bit is discarded.)

If the FIFOs are disabled (the UARTi.UART_FCR[0] FIFO_EN bit is set to 0), the DMA occurs in single-character transfers.

When DMA mode 0 is programmed, the signals associated with DMA operation are not active.

Depending on UART_MDR3[2] SET_DMA_TX_THRESHOLD, the threshold can be programmed different ways:

- SET_TX_DMA_THRESHOLD = 1:

  The threshold value will be the value of the UART_TX_DMA_THRESHOLD register. If SET_TX_DMA_THRESHOLD + TX trigger spaces 64, then the default method of threshold is used: threshold value = TX FIFO size.
- SET_TX_DMA_THRESHOLD = 0:

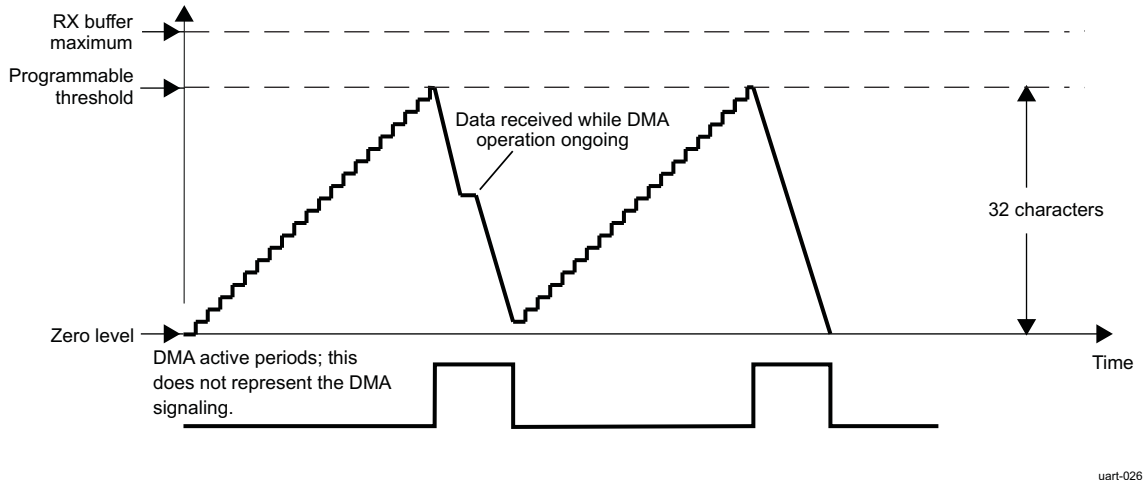
Copyright © 2011, Texas Instruments Incorporated

The threshold value = TX FIFO size TX trigger space. The TX DMA line is asserted if the TX FIFO level is lower then the threshold. It remains asserted until TX trigger spaces number of bytes are written into the FIFO. The DMA line is then deasserted and the FIFO level is compared with the threshold value.

19.3.6.4.1 DMA Transfers (DMA Mode 1, 2, or 3)

Figure 19-7 through Figure 19-10 show the supported DMA operations.

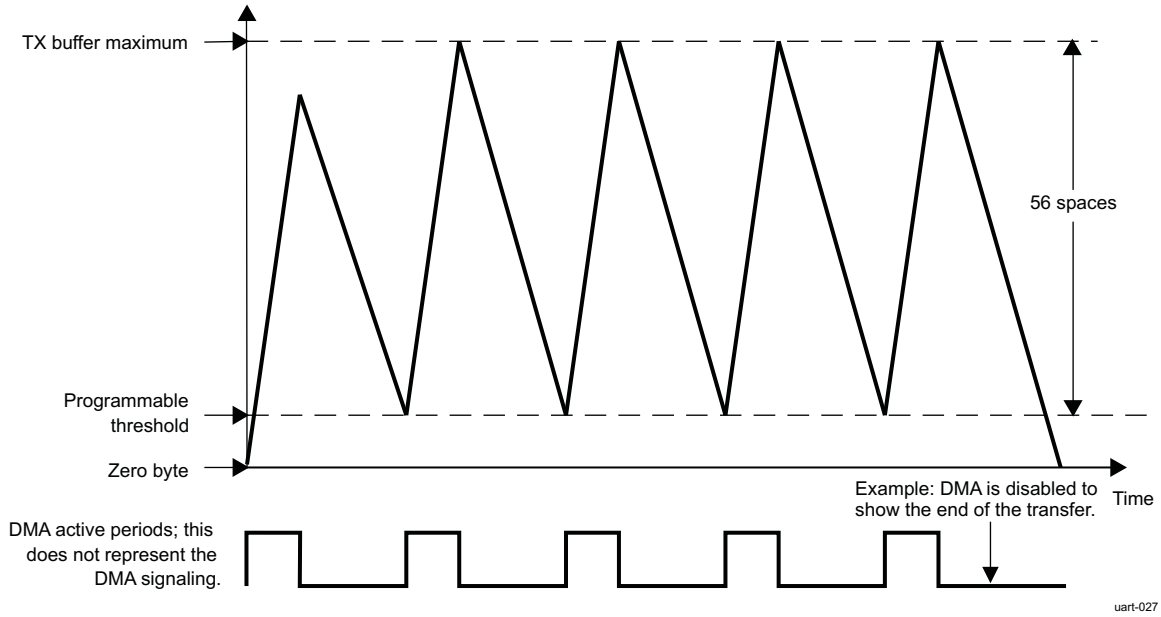
Figure 19-7. Receive FIFO DMA Request Generation (32 Characters)



In receive mode, a DMA request is generated when the RX FIFO reaches its threshold level defined in the trigger level register (UARTi.UART_TLR). This request is deasserted when the number of bytes defined by the threshold level is read by the sDMA.

In transmit mode, a DMA request is automatically asserted when the TX FIFO is empty. This request is deasserted when the number of bytes defined by the number of spaces in the UARTi.UART_TLR register is written by the sDMA. If an insufficient number of characters is written, the DMA request stays active.

Figure 19-8. Transmit FIFO DMA Request Generation (56 Spaces)



The DMA request is again asserted if the FIFO can receive the number of bytes defined by the UARTi.UART_TLR register.

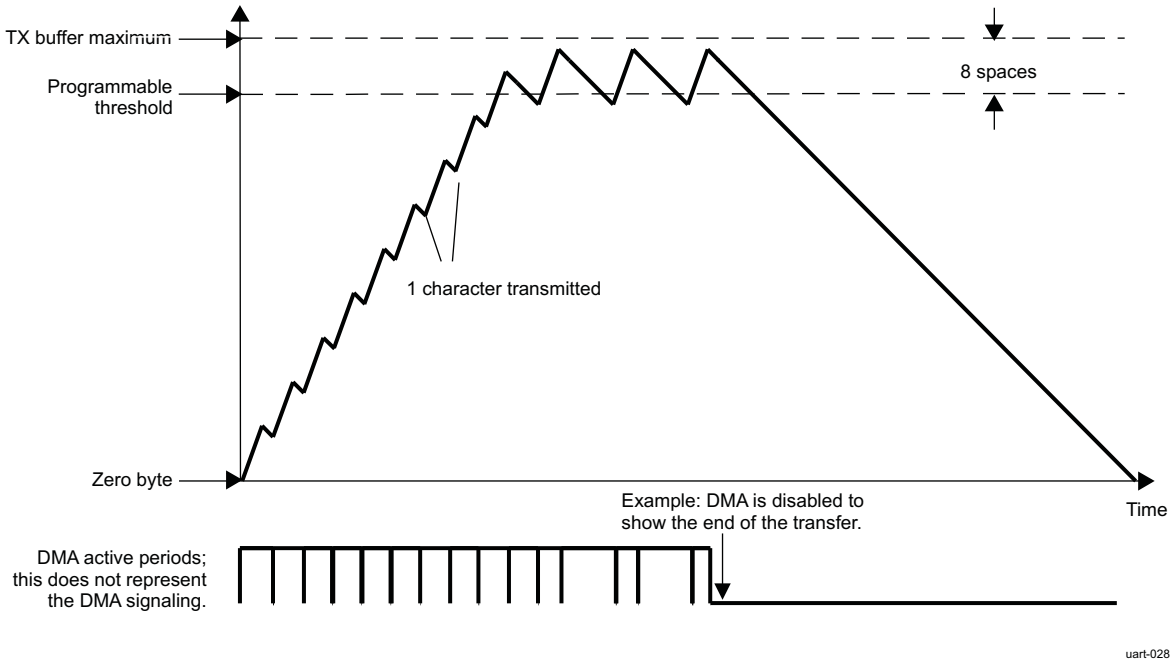
Copyright © 2011, Texas Instruments Incorporated

The threshold can be programmed in a number of ways. Figure 19-8 shows a DMA transfer operating with a space setting of 56 that can arise from using the auto settings in the UARTi.UART_FCR[5:4] TX_FIFO_TRIG bit field or the UARTi.UART_TLR[3:0] TX_FIFO_TRIG_DMA bit field concatenated with the TX_FIFO_TRIG bit field.

The setting of 56 spaces in the UART/IrDA/CIR module must correlate with the settings of the sDMA so that the buffer does not overflow (program the DMA request size of the LH controller to equal the number of spaces in the UART/IrDA/CIR module).

Figure 19-9 shows an example with eight spaces to show the buffer level crossing the space threshold. The LH DMA controller settings must correspond to those of the UART/IrDA/CIR module.

Figure 19-9. Transmit FIFO DMA Request Generation (8 Spaces)



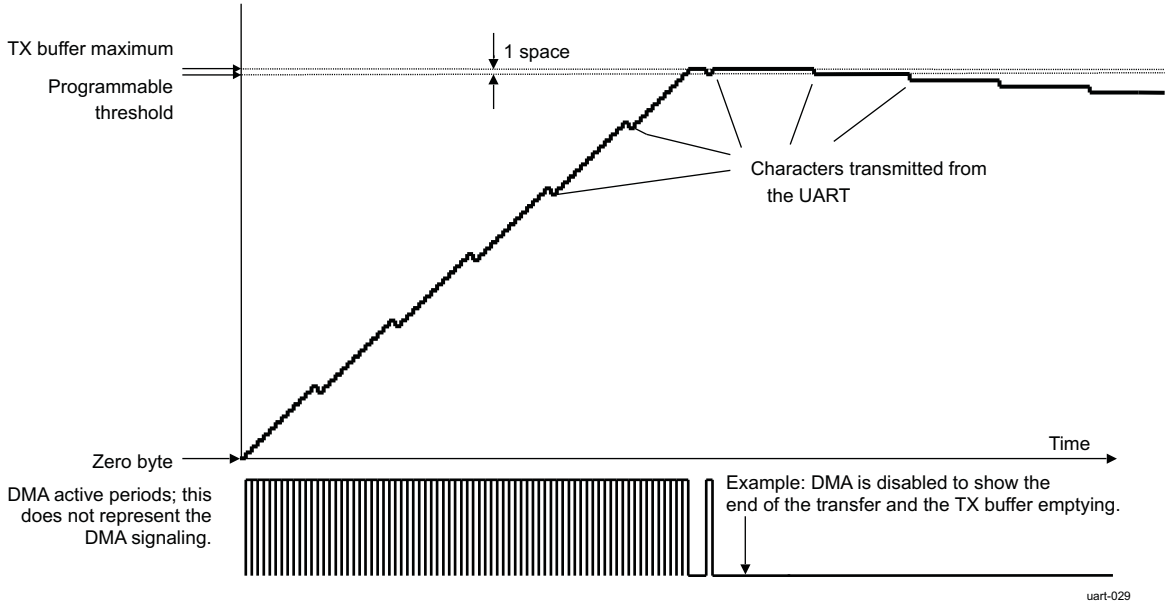
The next example shows the setting of one space that uses the DMA for each transfer of one character to the transmit buffer (see Figure 19-10). The buffer is filled faster than the baud rate at which data is transmitted to the TX pin. Eventually, the buffer is completely full and the DMA operations stop transferring data to the transmit buffer.

On two occasions, the buffer holds the maximum amount of data words; shortly after this, the DMA is disabled to show the slower transmission of the data words to the TX pin. Eventually, the buffer is emptied at the rate specified by the baud rate settings of the UARTi.UART_DLL and UARTi.UART_DLH registers.

The DMA settings must correspond to the system LH DMA controller settings to ensure correct operation of this logic.

Copyright © 2011, Texas Instruments Incorporated

Figure 19-10. Transmit FIFO DMA Request Generation (1 Space)



The final example shows the setting of eight spaces, but setting the TX DMA threshold directly by setting the UART_MDR3[1] NONDEFAULT_FREQ bit and the UART_TX_DMA_THRESHOLD register (see Figure 19-11). In the example, UART_TX_DMA_THRESHOLD[2:0] TX_DMA_THRESHOLD = 3 and the trigger level is 8. The buffer is filled at a faster rate than the baud rate transmits data to the TX pin. The buffer is filled with 8 bytes and the DMA operations stop transferring data to the transmit buffer. When the buffer is emptied to the threshold level by transmission, the DMA operation activates again to fill the buffer with 8 bytes.

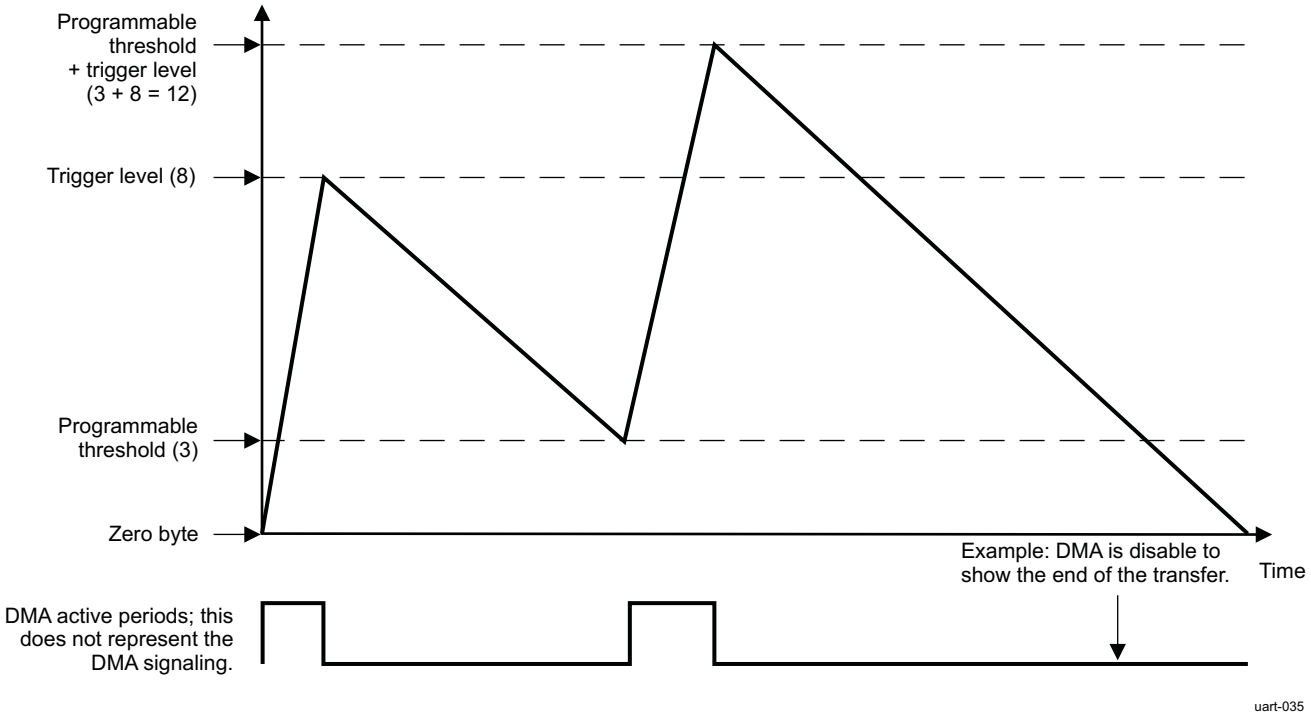
Eventually, the buffer is emptied at the rate specified by the baud rate settings of the UART_DLL and UART_DLH registers.

If the selected threshold level plus the trigger level exceed the maximum buffer size, the original TX DMA threshold method is used to prevent TX overrun, regardless of the value of the UART_MDR3[1] NONDEFAULT_FREQ bit.

The DMA settings must correspond to the settings of the system local host DMA controller to ensure the correct operation of this logic.

Copyright © 2011, Texas Instruments Incorporated

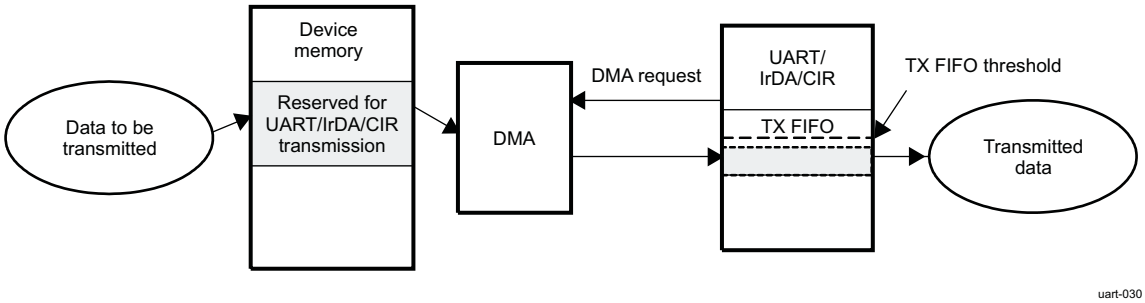
Figure 19-11. Transmit FIFO DMA Request Generation Using Direct TX DMA Threshold Programming. (Threshold = 3; Spaces = 8)



19.3.6.4.2 DMA Transmission

Figure 19-12 shows DMA transmission.

Figure 19-12. DMA Transmission



1. Data to be transmitted are put in the device memory reserved for UART/IrDA/CIR transmission by the DMA:
   (a) Until the TX FIFO trigger level is not reached, a DMA request is generated
   (b) An element (1 byte) is transferred from the SDRAM to the TX FIFO at each DMA request (DMA element synchronization).
2. Data in the TX FIFO are automatically transmitted.
3. The end of the transmission is signaled by the UARTi.UART_THR empty (TX FIFO empty).

NOTE: In IrDA mode, the transmission does not end immediately after the TX FIFO empties, at which point the last data byte, the CRC field, and the stop flag still must be transmitted; thus, the end of transmission occurs a few milliseconds after the UARTi.UART_THR register empties.

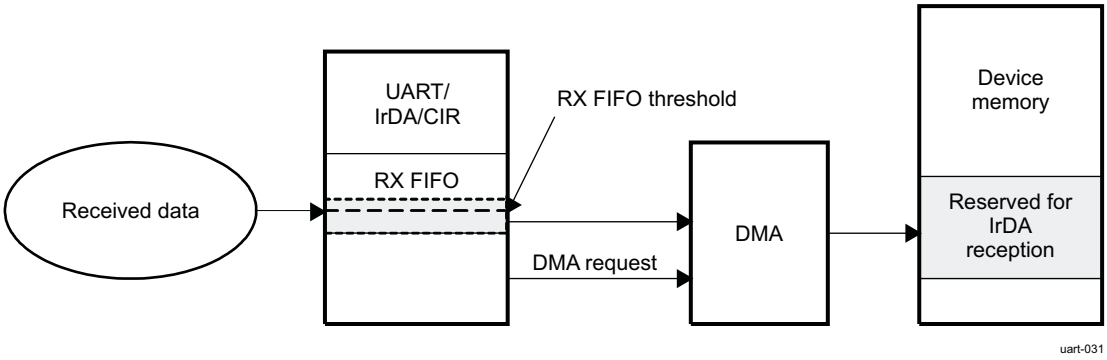
19.3.6.4.3 DMA Reception

Figure 19-13 shows DMA reception.

Figure 19-13. DMA Reception



1. Enable the reception.
2. Received data are put in the RX FIFO.
3. Data are transferred from the RX FIFO to the device memory by the DMA:
   (a) At each received byte, the RX FIFO trigger level (one character) is reached and a DMA request is generated.
   (b) An element (1 byte) is transferred from the RX FIFO to the SDRAM at each DMA request (DMA element synchronization).
4. The end of the reception is signaled by the EOF interrupt.

19.3.7 Mode Selection

19.3.7.1 Register Access Modes

19.3.7.1.1 Operational Mode and Configuration Modes

Register access depends on the register access mode, although register access modes are not correlated to functional mode selection. Three different modes are available:

- Operational mode
- Configuration mode A
- Configuration mode B

Operational mode is the selected mode when the function is active; serial data transfer can be performed in this mode.

Configuration mode A and configuration mode B are used during module initialization steps. These modes enable access to configuration registers, which are hidden in the operational mode. The modes are used when the module is inactive (no serial data transfer processed) and only for initialization or reconfiguration of the module.

The value of the UARTi.UART_LCR register determines the register access mode (see Table 19-16).

Table 19-16. UART/IrDA/CIR Register Access Mode Programming (Using UART_LCR)

Mode	Condition
Configuration mode A	UART_LCR[7] = 0x1 and UART_LCR[7:0] != 0xBF
Configuration mode B	UART_LCR[7] = 0x1 and UART_LCR[7:0] = 0xBF
Operational mode	UART_LCR[7] = 0x0

Copyright © 2011, Texas Instruments Incorporated

19.3.7.1.2 Register Access Submode

In each access register mode (operational mode or configuration mode A/B), some register accesses are conditional on the programming of a submode (MSR_SPR, TCR_TLR, and XOFF). These registers are identified in , *UART/IrDA/CIR Register Manual*.

Table 19-17 through Table 19-19 summarize the register access submodes.

Table 19-17. Subconfiguration Mode A Summary

Mode	Condition
MSR_SPR	(UART_EFR[4] = 0x0 or UART_MCR[6] = 0x0)
TCR_TLR	UART_EFR[4] = 0x1 and UART_MCR[6] = 0x1

Table 19-18. Subconfiguration Mode B Summary

Mode	Condition
TCR_TLR	UART_EFR[4] = 0x1 and UART_MCR[6] = 0x1
XOFF	(UART_EFR[4] = 0x0 or UART_MCR[6] = 0x0)

Table 19-19. Suboperational Mode Summary

Mode	Condition
MSR_SPR	UART_EFR[4] = 0x0 or UART_MCR[6] = 0x0
TCR_TLR	UART_EFR[4] = 0x1 and UART_MCR[6] = 0x1

19.3.7.1.3 Registers Available for the Register Access Modes

Table 19-20 lists the names of the register bits in each access register mode. Gray shading indicates that the register does not depend on the register access mode (available in all modes).

Table 19-20. UART/IrDA/CIR Register Access Mode Overview

Address Offset	Registers					
	Configuration Mode A		Configuration Mode B		Operational Mode	
	Read	Write	Read	Write	Read	Write
0x000	UART_DLL	UART_DLL	UART_DLL	UART_DLL	UART_RHR	UART_THR
0x004	UART_DLH	UART_DLH	UART_DLH	UART_DLH	UART_IER	UART_IER
0x008	UART_IIR	UART_FCR	UART_EFR	UART_EFR	UART_IIR	UART_FCR
0x00C	UART_LCR	UART_LCR	UART_LCR	UART_LCR	UART_LCR	UART_LCR
0x010	UART_MCR	UART_MCR	UART_XON1_ADDR1	UART_XON1_ADDR1	UART_MCR	UART_MCR
0x014	UART_LSR	–	UART_XON2_ADDR2	UART_XON2_ADDR2	UART_LSR	–
0x018	UART_MSR (1)/UART_TCR (2)	UART_TCR (2)	UART_TCR (2)/UART_XOFF1 (3)	UART_TCR (2)/UART_XOFF1 (3)	UART_MSR (1)/UART_TCR (2)	UART_TCR (2)

19.3.8 Protocol Formatting

The UART/IRDA module can operate in seven different modes:

1. UART 16x mode (≤230.4 Kbits/s), UART16x ≤460Kbits/s if MDR3[1] is set
2. UART 16x mode with autobauding (≥1200 bits/s and ≤115.2 Kbits/s) if MDR3[1] is not set
3. UART 13x mode (≥460.8 Kbits/s) if MDR3[1] is not set
4. IrDA SIR mode (≤115.2 Kbits/s) if MDR3[1] is not set
5. IrDA MIR mode (0.576 and 1.152 Mbits/s) if MDR3[1] is not set
6. IrDA FIR mode (4 Mbits/s) if MDR3[1] is not set
7. CIR mode (programmable modulation rates specific to remote control applications) if MDR3[1] is not set

The module performs a serial-to-parallel conversion on received data characters and a parallel-to-serial conversion on transmitted data characters by the processor. The complete status of each channel of the module and each received character/frame can be read at any time during functional operation via the line status register (LSR).

The module can be placed in an alternate mode (FIFO mode) to relieve the processor of excessive software overhead by buffering received/transmitted characters.

Both the receiver and transmitter FIFOs can store up to 64 bytes of data (plus three additional bits of error status per byte for the receiver FIFO) and have selectable trigger levels. Both interrupts and DMA are available to control the data flow between the LH and the module.

19.3.8.1 UART Mode

The UART uses a wired interface for serial communication with a remote device.

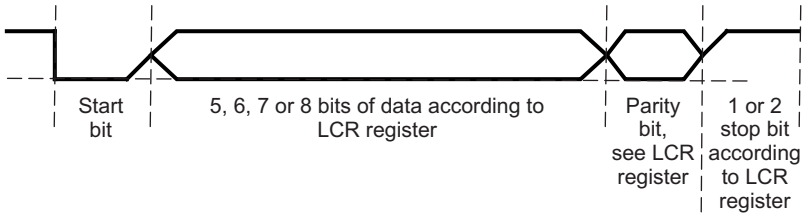
The UART module is functionally compatible with the TL16C750 UART and is also functionally compatible

Copyright © 2011, Texas Instruments Incorporated

to earlier designs, such as the TL16C550. The UART module can use hardware or software flow control to manage transmission and reception. Hardware flow control significantly reduces software overhead and increases system efficiency by automatically controlling serial data flow using the RTS output and CTS input signals. Software flow control automatically controls data flow by using programmable XON/XOFF characters.

The UART modem module is enhanced with an autobauding functionality which in control mode allows to automatically set the speed, the number of bit per character, the parity selected.

Figure 19-14. UART Data Format

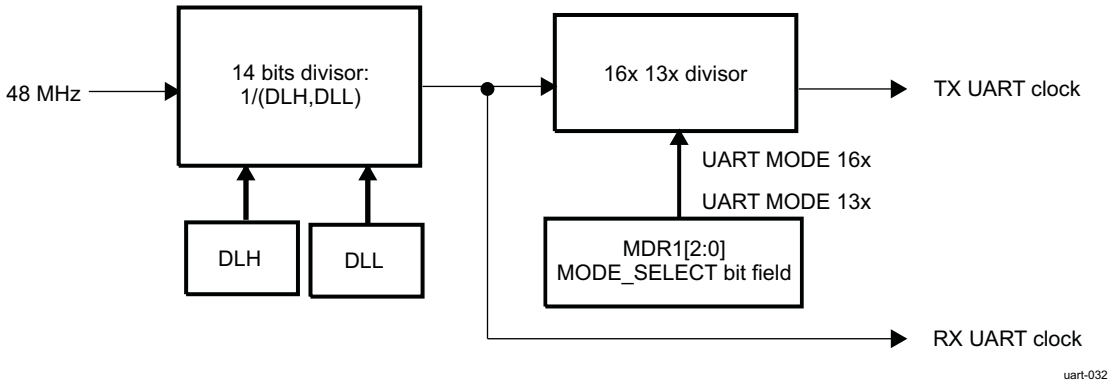


19.3.8.1.1 UART Clock Generation: Baud Rate Generation

The UART function contains a programmable baud generator and a set of fixed dividers that divide the 48-MHz clock input down to the expected baud rate.

Figure 19-15 shows the baud rate generator and associated controls.

Figure 19-15. Baud Rate Generation



CAUTION

Before initializing or modifying clock parameter controls (UARTi.UART_DLH, UARTi.UART_DLL), MODE_SELECT = DISABLE (UARTi.UART_MDR1[2:0]) must be set to 0x7. Failure to observe this rule can result in unpredictable module behavior.

19.3.8.1.2 Choosing the Appropriate Divisor Value

Two divisor values are:

- UART 16x mode: Divisor value = Operating frequency/(16x baud rate)
- UART 13x mode: Divisor value = Operating frequency/(13x baud rate)

Table 19-25 describes the UART baud rate settings.

Copyright © 2011, Texas Instruments Incorporated

19.3.8.1.3 UART Data Formatting

The UART can use hardware flow control to manage transmission and reception. Hardware flow control significantly reduces software overhead and increases system efficiency by automatically controlling serial data flow using the RTS output and CTS input signals.

The UART is enhanced with the autobauding function. In control mode, autobauding lets the speed, the number of bits per character, and the parity selected be set automatically.

19.3.8.1.3.1 Frame Formatting

When autobauding is not used, frame format attributes must be defined in the UARTi.UART_LCR register.

Character length is specified using the UARTi.UART_LCR[1:0] CHAR_LENGTH bit field.

The number of stop-bits is specified using the UARTi.UART_LCR[2] NB_STOP bit.

The parity bit is programmed using the UARTi.UART_LCR[5:3] PARITY_EN, PARITY_TYPE_1, and PARITY_TYPE_2 bit fields (see Table 19-26).

Table 19-26. UART Parity Bit Encoding

PARITY_EN	PARITY_TYPE_1	PARITY_TYPE_2	Parity
0	N/A	N/A	No parity
1	0	0	Odd parity
1	1	0	Even parity
1	0	1	Forced 1
1	1	1	Forced 0

19.3.8.1.3.2 Hardware Flow Control

Hardware flow control is composed of auto-CTS and auto-RTS. Auto-CTS and auto-RTS can be enabled and disabled independently by programming the UARTi.UART_EFR[7:6] AUTO_CTS_EN and AUTO_RTS_EN bit fields, respectively.

With auto-CTS, uarti_cts must be active before the module can transmit data.

Copyright © 2011, Texas Instruments Incorporated

Auto-RTS activates the uarti_rts output only when there is enough room in the RX FIFO to receive data. It deactivates the uarti_rts output when the RX FIFO is sufficiently full. The HALT and RESTORE trigger levels in the UARTi.UART_TCR register determine the levels at which uarti_rts is activated and deactivated.

If auto-CTS and auto-RTS are enabled, data transmission does not occur unless the RX FIFO has empty space. Thus, overrun errors are eliminated during hardware flow control. If auto-CTS and auto-RTS are not enabled, overrun errors occur if the transmit data rate exceeds the RX FIFO latency.

- Auto-RTS:

  Auto-RTS data flow control originates in the receiver block. The RX FIFO trigger levels used in auto-RTS are stored in the UARTi.UART_TCR register. uarti_rts is active if the RX FIFO level is below the HALT trigger level in the UARTi.UART_TCR[3:0] RX_FIFO_TRIG_HALT bit field. When the RX FIFO HALT trigger level is reached, uarti_rts is deasserted. The sending device (for example, another UART) can send an additional byte after the trigger level is reached because it may not recognize the deassertion of RTS until it begins sending the additional byte.

  uarti_rts is automatically reasserted when the RX FIFO reaches the RESUME trigger level programmed by the UARTi.UART_TCR[7:4] RX_FIFO_TRIG_START bit field. This reassertion requests the sending device to resume transmission.

  In this case, uarti_rts is an active-low signal.

- Auto-CTS:

  The transmitter circuitry checks uarti_cts before sending the next data byte. When uarti_cts is active, the transmitter sends the next byte. To stop the transmitter from sending the next byte, uarti_cts must be deasserted before the middle of the last stop-bit currently sent.

  The auto-CTS function reduces interrupts to the host system. When auto-CTS flow control is enabled, the uarti_cts state changes do not have to trigger host interrupts because the device automatically controls its own transmitter. Without auto-CTS, the transmitter sends any data present in the transmit FIFO, and a receiver overrun error can result.

  In this case, uarti_cts is an active-low signal.

19.3.8.1.3.3 Software Flow Control

Software flow control is enabled through the enhanced feature register (UARTi.UART_EFR) and the modem control register (UARTi.UART_MCR). Different combinations of software flow control can be enabled by setting different combinations of the UARTi.UART_EFR[3:0] bit field (see Table 19-27).

Two other enhanced features relate to software flow control:

- XON any function (UARTi.UART_MCR[5]): Operation resumes after receiving any character after the XOFF character is recognized. If special character detect is enabled and special character is received after XOFF1, it does not resume transmission. The special character is stored in the RX FIFO.

  NOTE: The XON-any character is written into the RX FIFO even if it is a software flow character.

- Special character (UARTi.UART_EFR[5]): Incoming data is compared to XOFF2. When the special character is detected, the XOFF interrupt (UARTi.UART_IIR[4]) is set, but it does not halt transmission. The XOFF interrupt is cleared by a read of UARTi.UART_IIR. The special character is transferred to the RX FIFO. Special character does not work with XON2, XOFF2, or sequential XOFFs.

Table 19-27. UART_EFR[3:0] Software Flow Control Options

Bit 3	Bit 2	Bit 1	Bit 0	TX, RX Software Flow Controls
0	0	X	X	No transmit flow control
1	0	X	X	Transmit XON1, XOFF1
0	1	X	X	Transmit XON2, XOFF2

Copyright © 2011, Texas Instruments Incorporated

Table 19-27. UART_EFR[3:0] Software Flow Control Options (continued)

Bit 3	Bit 2	Bit 1	Bit 0	TX, RX Software Flow Controls
1	1	X	X	Transmit XON1, XON2: XOFF1, XOFF2(1)
X	X	0	0	No receive flow control
X	X	1	0	Receiver compares XON1, XOFF1
X	X	0	1	Receiver compares XON2, XOFF2
X	X	1	1	Receiver compares XON1, XON2: XOFF1, XOFF2(1)

(1) In these cases, the XON1 and XON2 characters or the XOFF1 and XOFF2 characters must be transmitted/received sequentially with XON1/XOFF1 followed by XON2/XOFF2.
XON1 is defined in the UARTi.UART_XON1_ADDR1[7:0] XON_WORD1 bit field. XON2 is defined in the UARTi.UART_XON2_ADDR2[7:0] XON_WORD2 bit field.
XOFF1 is defined in the UARTi.UART_XOFF1[7:0] XOFF_WORD1 bit field. XOFF2 is defined in the UARTi.UART_XOFF2[7:0] XOFF_WORD2 bit field.

19.3.8.1.3.3.1 Receive (RX)

When software flow control operation is enabled, the UART compares incoming data with XOFF1/2 programmed characters (in certain cases, XOFF1 and XOFF2 must be received sequentially). When the correct XOFF characters are received, transmission stops after transmission of the current character completes. Detection of XOFF also sets the UARTi.UART_IIR[4] bit (if enabled by UARTi.UART_IER[5]) and causes the interrupt line to go low.

To resume transmission, an XON1/2 character must be received (in certain cases, XON1 and XON2 must be received sequentially). When the correct XON characters are received, the UARTi.UART_IIR[4] bit is cleared and the XOFF interrupt disappears.

NOTE: When a parity, framing, or break error occurs while receiving a software flow control character, this character is treated as normal data and is written to the RX FIFO.

When XON-any and special character detect are disabled and software flow control is enabled, no valid XON or XOFF characters are written to the RX FIFO. For example, when UARTi.UART_EFR[1:0] = 0x2, if XON1 and XOFF1 characters are received, they are not written to the RX FIFO.

When pairs of software flow characters are programmed to be received sequentially (UARTi.UART_EFR[1:0] = 0x3), the software flow characters are not written to the RX FIFO if they are received sequentially. However, received XON1/XOFF1 characters must be written to the RX FIFO if the subsequent character is not XON2/XOFF2.

19.3.8.1.3.3.2 Transmit (TX)

Two XOFF1 characters are transmitted when the RX FIFO passes the trigger level programmed by UARTi.UART_TCR[3:0]. As soon as the RX FIFO reaches the trigger level programmed by UARTi.UART_TCR[7:4], two XON1 characters are sent, so the data transfer recovers.

NOTE: If software flow control is disabled after an XOFF character is sent, the module transmits XON characters automatically to enable normal transmission.

The transmission of XOFF(s)/XON(s) follows the same protocol as transmission of an ordinary byte from the TX FIFO. This means that even if the word length is 5, 6, or 7 characters, the 5, 6, or 7 LSBs of XOFF1/2 and XON1/2 are transmitted. The 5, 6, or 7 bits of a character are seldom transmitted, but this function is included to maintain compatibility with earlier designs.

It is assumed that software flow control and hardware flow control are never enabled simultaneously.

Copyright © 2011, Texas Instruments Incorporated

19.3.8.1.3.4 Autobauding Modes

In autobauding mode, the UART can extract transfer characteristics (speed, length, and parity) from an "at" (AT) command (ASCII code). These characteristics are used to receive data after an AT and to send data.

The following AT commands are valid:

AT	DATA	<CR>
at	DATA	<CR>
A/		
a/		

A line break during the acquisition of the sequence AT is not recognized, and an echo function is not implemented in hardware.

A/ and a/ are not used to extract characteristics, but they must be recognized because of their special meaning. A/ or a/ is used to instruct the software to repeat the last received AT command; therefore, an a/ always follows an AT, and transfer characteristics are not expected to change between an AT and an a/.

When a valid AT is received, AT and all subsequent data, including the final <CR> (0x0D), are saved to the RX FIFO. The autobaud state-machine waits for the next valid AT command. If an a/ (A/) is received, the a/ (A/) is saved in the RX FIFO and the state-machine waits for the next valid AT command.

On the first successful detection of the baud rate, the UART activates an interrupt to signify that the AT (upper or lower case) sequence is detected. The UARTi.UART_UASR register reflects the correct settings for the baud rate detected. Interrupt activity can continue in this fashion when a subsequent character is received. Therefore, it is recommended that the software enable the RHR interrupt when using the autobaud mode.

The following settings are detected in autobaud mode with a module clock of 48 MHz:

- Speed:
  - 115.2K baud
  - 57.6K baud
  - 38.4K baud
  - 28.8K baud
  - 19.2K baud
  - 14.4K baud
  - 9.6K baud
  - 4.8K baud
  - 2.4K baud
  - 1.2K baud
- Length: 7 or 8 bits
- Parity: Odd, even, or space

NOTE: The combination of 7-bit character plus space parity is not supported.

Autobauding mode is selected when the UARTi.UART_MDR1[2:0] MODE_SELECT bit field is set to 0x2. In UART autobauding mode, UARTi.UART_DLL, UARTi.UART_DLH, and UARTi.UART_LCR[5:0] bit field settings are not used; instead, UART_UASR is updated with the configuration detected by the autobauding logic.

UART_UASR Autobauding Status Register Use

This register is used to set up transmission according to the characteristics of the previous reception instead of the UARTi.UART_LCR, UARTi.UART_DLL, and UARTi.UART_DLH registers when the UART is in autobauding mode.

Copyright © 2011, Texas Instruments Incorporated

To reset the autobauding hardware (to start a new AT detection) or to set the UART in standard mode (no autobaud), the UARTi.UART_MDR1[2:0] MODE_ SELECT bit field must be set to reset state (0x7) and then to the UART in autobauding mode (0x2) or to the UART in standard mode (0x0).

Use limitation:

- Only 7- and 8-bit characters (5- and 6-bit not supported)
- 7-bit character with space parity not supported
- Baud rate between 1200 and 115,200 bps (10 possibilities)

19.3.8.1.3.5 Error Detection

When the UARTi.UART_LSR register is read, the UARTi.UART_LSR[4:2] bit field reflects the error bits (BI: break condition, FE: framing error, PE: parity error) of the character at the top of the RX FIFO (the next character to be read). Therefore, reading the UARTi.UART_LSR register and then reading the UARTi.UART_RHR register identifies errors in a character.

Reading the UARTi.UART_RHR register updates the BI, FE, and PE bits (see Table 19-11 for the UART mode interrupts).

The UARTi.UART_LSR[7] RX_FIFO_STS bit is set when there is an error in the RX FIFO and is cleared only when no errors remain in the RX FIFO.

NOTE: Reading the UARTi.UART_LSR register does not cause an increment of the RX FIFO read pointer. The RX FIFO read pointer is incremented by reading the UARTi.UART_RHR register.

Reading the UARTi.UART_LSR register clears the OE bit if it is set (see Table 19-11 for the UART mode interrupts).

19.3.8.1.3.6 Overrun During Receive

Overrun during receive occurs if the RX state-machine tries to write data into the RX FIFO when it is already full. When overrun occurs, the device interrupts the MPU with the UARTi.UART_IIR[5:1] IT_TYPE bit field set to 0x3 (receiver line status error) and discards the remaining portion of the frame.

Overrun also causes an internal flag to be set, which disables further reception. Before the next frame can be received, the MPU must:

- Reset the RX FIFO.
- Read the UARTi.UART_RESUME register, which clears the internal flag.

19.3.8.1.3.7 Time-Out and Break Conditions

19.3.8.1.3.7.1 Time-Out Counter

An RX idle condition is detected when the receiver line (uarti_rx) is high for a time that equals 4x the programmed word length + 12 bits. uarti_rx is sampled midway through each bit.

For sleep mode, the counter is reset when there is activity on uarti_rx.

For the time-out interrupt, the counter counts only when there is data in the RX FIFO, and the count is reset when there is activity on uarti_rx or when the UARTi.UART_RHR register is read.

19.3.8.1.3.7.2 Break Condition

When a break condition occurs, uarti_tx is pulled low. A break condition is activated by setting the UARTi.UART_LCR[6] BREAK_EN bit. The break condition is not aligned on word stream (a break condition can occur in the middle of a character). The only way to send a break condition on a full character is:

1. Reset the TX FIFO (if enabled).
2. Wait for the transmit shift register to empty (the UARTi.UART_LSR[6] TX_SR_E bit is set to 1).

Copyright © 2011, Texas Instruments Incorporated

3. Take a guard time according to stop-bit definition.
4. Set the BREAK_EN bit to 1.

The break condition is asserted while the BREAK_EN bit is set to 1.

The time-out counter and break condition apply only to UART modem operation and not to IrDA/CIR mode operation.

19.3.8.2 IrDA Mode

19.3.8.2.1 SIR Mode

In slow infrared (SIR) mode, data transfers take place between the LH and peripheral devices at speeds of up to 115200 bauds. A SIR transmit frame starts with start flags (either a single 0xC0, multiple 0xC0, or a single 0xC0 preceded by a number of 0xFF flags), followed by frame data, CRC-16, and ends with a stop flag (0xC1). The bit format for a single word uses a single start bit, eight data bits, and one stop bit. The format is unaffected by the use and settings of the LCR register.

Note that BLR[6] is used to select whether to use 0xC0 or 0xFF start patterns when multiple start flags are required.

The SIR transmit state machine attaches start flags, CRC-16, and stop flags. It checks the outgoing data to establish if data transparency is required.

SIR transparency is carried out if the outgoing data, between the start and stop flags, contains 0xC0, 0xC1, or 0x7D. If one of these is about to be transmitted, then the SIR state machine sends an escape character (0x7D) first, then inverts the fifth bit of the real data to be sent and sends this data immediately after the 0x7D character.

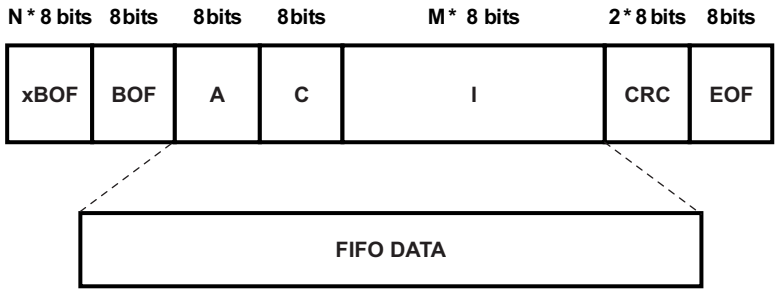
The SIR receive state machine recovers the receive clock, removes the start flags, removes any transparency from the incoming data, and determines frame boundary with reception of the stop flag. It also checks for errors, such as frame abort (0x7D character followed immediately by a 0xC1 stop flag, without transparency), CRC error, and frame-length error. At the end of a frame reception, the LH reads the line status register (LSR) to find out possible errors of the received frame.

Data can be transferred both ways by the module, but when the device is transmitting the IR RX circuitry is automatically disabled by hardware. See bit 5 in Section 19.5.26, *Auxiliary Control Register*, for a description of the logical operation. **Note:** This applies to all three modes SIR, MIR, and FIR.

The infrared output in SIR mode can either be 1.6µs or 3/16 encoding, selected by the PULSETYPE bit of the Auxiliary Control Register (ACREG[7]). In 1.6µs encoding, the infrared pulse width is 1.6µs and in 3/16 encoding the infrared pulse width is 3/16 of a bit duration (1/baud-rate). The receiver supports both 3/16 and 1.6µs pulse duration by default. The transmitting device must send at least two start flags at the start of each frame for back-to-back frames. **Note:** Reception supports variable-length stop bits.

19.3.8.2.1.1 Frame Format

Figure 19-16. IrDA SIR Frame Format



The CRC is applied on the address (A), control (C) and information (I) bytes.

Note: The two words of CRC are written in the FIFO in reception.

Copyright © 2011, Texas Instruments Incorporated

19.3.8.2.1.2 Asynchronous Transparency

Before transmitting a byte, the UART IrDA controller examines each byte of the payload and the CRC field (between BOF and EOF). For each byte equal to 0xC0 (BOF), 0xC1 (EOF), or 0x7D (control escape) it does the following.

In transmission

1. Inserts a control escape (CE) byte preceding the byte.
2. Complements bit 5 of the byte (i.e., exclusive OR's the byte with 0x20).

The byte sent for the CRC computation is the initial byte written in the TX FIFO (before the XOR with 0x20).

In reception

For the A, C, I, CRC field:

1. Compare the byte with CE byte, and if not equal send it to the CRC detector and store it in the RX FIFO.
2. If equal to CE, discard the CE byte.
3. Complements the bit 5 of the byte following the CE.
4. 4. Send the complemented byte to the CRC detector and store it in the RX FIFO.

19.3.8.2.1.3 Abort Sequence

The transmitter may decide to prematurely close a frame. The transmitter aborts by sending the following sequence: 0x7DC1. The abort pattern closes the frame without a CRC field or an ending flag.

It is possible to abort a transmission frame by programming the ABORTEN bit of the Auxiliary Control Register (ACREG[1]). When this bit is set to 1, 0x7D and 0xC1 are transmitted and the frame is not terminated with CRC or stop flags. The receiver treats a frame as an aborted frame when a 0x7D character, followed immediately by a 0xC1 character, has been received without transparency.

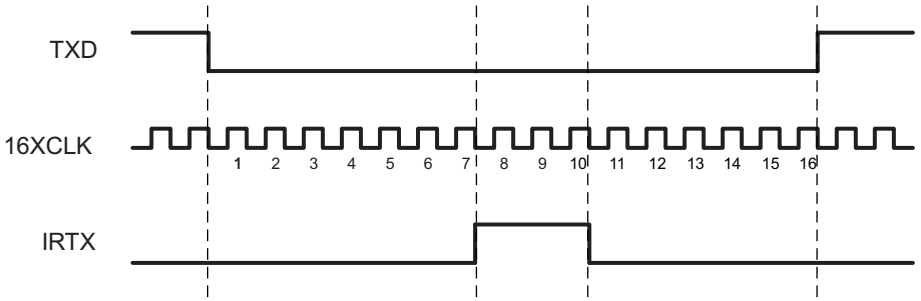
19.3.8.2.1.4 Pulse Shaping

In SIR mode, both the 3/16th and the 1.6µs pulse duration methods are supported in receive and transmit. ACREG[7] selects the pulse width method in transmit mode.

19.3.8.2.1.5 Encoder

Serial data from the transmit state machine is encoded to transmit data to the optoelectronics. While the serial data input to the (TXD) is high, the output (IRTX) is always low, and the counter used to form a pulse on IRTX is continuously cleared. After TXD resets to 0, IRTX rises on the falling edge of the 7th 16XCLK. On the falling edge of the 10th 16XCLK pulse, IRTX falls, creating a 3-clock-wide pulse. While TXD stays low, a pulse is transmitted during the 7th to the 10th clock of each 16-clock bit cycle.

Figure 19-17. IrDA Encoding Mechanism

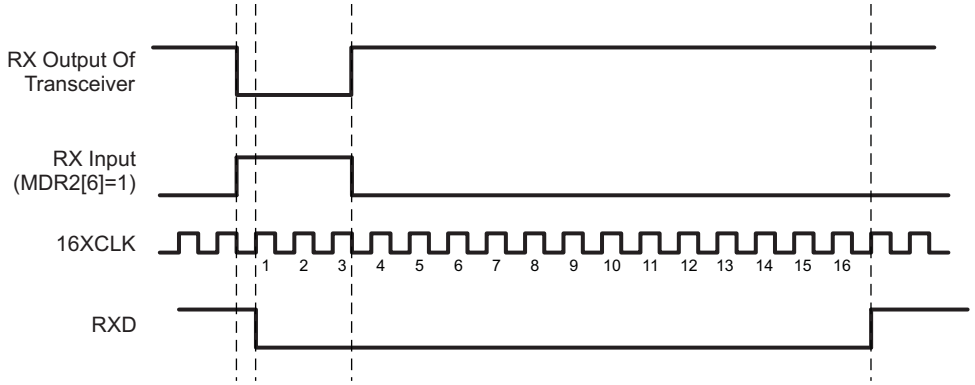


Copyright © 2011, Texas Instruments Incorporated

19.3.8.2.1.6 Decoder

After reset, RXD is high and the 4-bit counter is cleared. When a rising edge is detected on RX, RXD falls on the next rising edge of 16XCLK with sufficient setup time. RXD stays low for 16 cycles (16XCLK) and then returns to high as required by the IrDA specification. As long as no pulses (rising edges) are detected on the RX, RXD remains high.

Figure 19-18. IrDA Decoding Mechanism



The operation of the RX input can be disabled with DISIRRX bit of the Auxiliary Control Register (ACREG[5]). Furthermore, the MDR2[6] can be used to invert the signal from the transceiver (RX ouput) pin to the IRRX logic inside the UART.

19.3.8.2.1.7 IR Address Checking

In all IR modes, if address checking has been enabled, only frames intended for the device are written to the RX FIFO. This is to avoid receiving frames not meant for this device in a multi-point infrared environment. It is possible to program two frame addresses that the UART IrDA receives with XON1/ADDR1 and XON2/ADDR2 registers. Selecting address1 checking is done by setting EFR[0] to 1; address2 checking is done by setting EFR[1] to 1.

Setting EFR[1:0] to 0 disables all address checking operations. If both bits are set, then the incoming frame is checked for both private and public addresses. If address checking is disabled, then all received frames are written into the reception FIFO.

19.3.8.2.1.8 SIR Free Format Mode

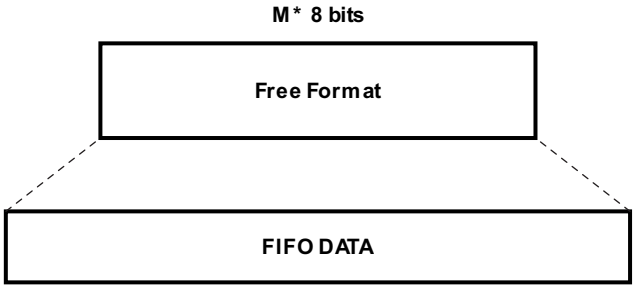
To allow complete software flexibility in the transmission and reception of Infrared data packets, the SIR free format mode is a sub-function of the existing SIR mode such that all frames going to and from the FIFO buffers are untouched with respect to appending and removing control characters and CRC values. In the transmission phase, the mode uses the IRTX pin, as in SIR mode.

This mode corresponds to a UART mode with a pulse modulation of 3/16 of baud-rate pulse width.

For example, a normal SIR packet has BOF control and CRC error checking data appended (transmitting) or removed (receiving) from the data going to and from the FIFOs. In SIR free format mode, only the data termed the FIFO DATA area, illustrated in Figure 19-19, would be transmitted and received.

Copyright © 2011, Texas Instruments Incorporated

Figure 19-19. SIR Free Format Mode



In this mode, the entire FIFO data packet is to be constructed (encoded and decoded) by the LH software.

The SIR free format mode is selected by setting the module in UART mode (MDR1[2:0] = 000) and the MDR2[3] register bit to one to allow the pulse shaping. As the bit format is to remain the same, some UART mode configuration registers need to be set at specific value:

- LCR[1:0] = “11” (8 data bits)
- LCR[2] = 0 (1 stop bit)
- LCR[3] = 0 (no parity)
- ACREG[7] = 0 (3/16 of baud-rate pulse width)

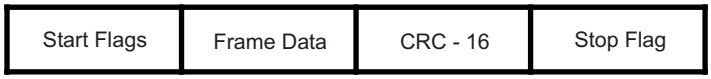
The features defined through MDR2[6] and ACREG[5] are also supported.

Note: - All other configuration registers need to be at the reset value. The UART mode interrupts are used for the SIR free format mode, but many of them are not relevant (e.g., XOFF, RTS, CTS, Modem status register).

19.3.8.2.2 MIR Mode

In medium infrared (MIR) mode, data transfers take place between LH and peripheral devices at 0.576 or 1.152 Mbits/s speed. A MIR transmit frame starts with start flags (at least two), followed by a frame data, CRC-16, and ends with a stop flag.

Figure 19-20. MIR Transmit Frame Format



On transmit, the MIR state machine attaches start flags, CRC-16, and stop flags. It also looks for five consecutive values of 1 in the frame data and automatically inserts a zero after five consecutive values of one (this is called bit stuffing).

On receive, the MIR receive state machine recovers the receive clock, removes the start flags, de-stuffs the incoming data, and determines frame boundary with reception of the stop flag. It also checks for errors, such as frame abort, CRC error, or frame-length error. At the end of a frame reception, the LH reads the line status register (LSR) to find possible errors of received frame.

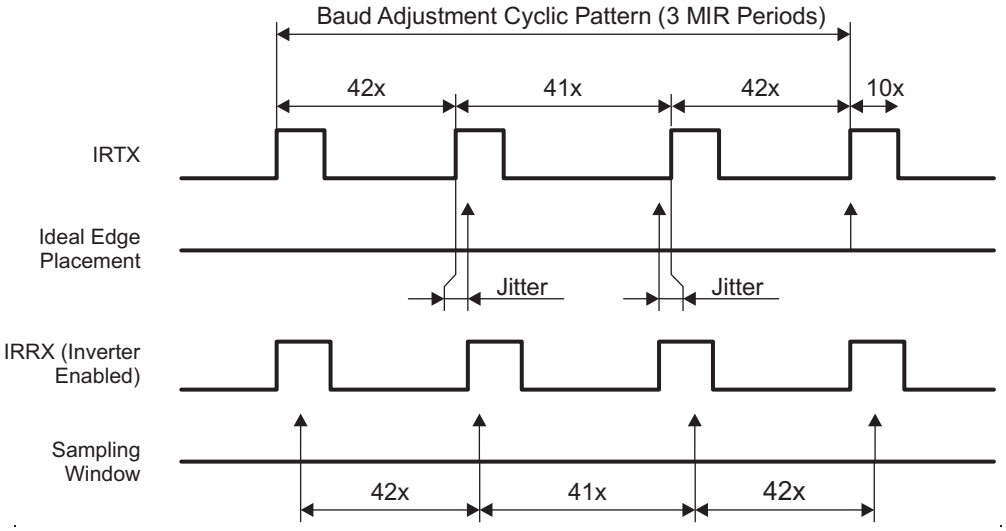
Data can be transferred both ways by the module but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware. See bit 5 in Section 19.5.26, *Auxiliary Control Register*, for a description of the logical operation. **Note:** This applies to all three modes SIR, MIR and FIR.

19.3.8.2.2.1 MIR Encoder/Decoder

In order to meet MIR baud-rate tolerance of +/-0.1% with a 48-MHz clock input, a 42-41-42 encoding/decoding adjustment is performed. The reference start point is the first start flag and the 42-41-42 cyclic pattern is repeated until the stop flag is sent or detected. The jitter created this way is within MIR tolerances. The pulse width is not exactly 1/4 but within tolerances defined by the IrDA specifications.

Copyright © 2011, Texas Instruments Incorporated

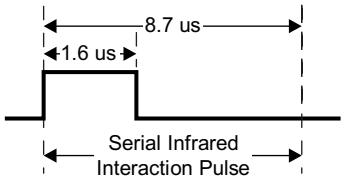
Figure 19-21. MIR BAUD Rate Adjustment Mechanism



19.3.8.2.2.2 SIP Generation

In MIR and FIR operation modes, the transmitter needs to send a serial infrared interaction pulse (SIP) at least once every 500 ms. The purpose of the SIP is to let slow devices (operating in SIR mode) know that the medium is currently occupied. The SIP pulse is shown in Figure 19-22

Figure 19-22. SIP Pulse



When the SIPMODE bit of Mode Definition Register 1 (MDR1[6]) equals 1, the TX state machine will always send one SIP at the end of a transmission frame. But when MDR1[6] = 0, the transmission of the SIP depends on the SENDSIP bit of the Auxiliary Control Register (ACREG[3]). The system (LH) can set ACREG[3] at least once every 500ms. The advantage of this approach over the default approach is that the TX state machine does not need to send the SIP at the end of each frame which may reduce the overhead required

19.3.8.2.3 FIR Mode

In fast infrared mode (FIR), data transfers take place between LH and peripheral devices at 4 Mbits/s speed. A FIR transmit frame starts with a preamble, followed by a start flag, frame data, CRC-32, and ends with a stop flag.

Figure 19-23. FIR Transmit Frame Format

Preamble (16x)	Start Flag	Frame Data	CRC - 32	Stop Flag

On transmit, the FIR transmit state machine attaches the preamble, start flag, CRC-32, and stop flag. It also encodes the transmit data into 4PPM format. It also generates the serial infrared interaction pulse (SIP).

Copyright © 2011, Texas Instruments Incorporated

On receive, the FIR receive state machine recovers the receive clock, removes the start flag, decodes the 4PPM incoming data, and determines frame boundary with a reception of the stop flag. It also checks for errors such as an illegal symbol, a CRC error, and a frame-length error. At the end of a frame reception, the LH reads the line status register (LSR) to find out possible errors of the received frame.

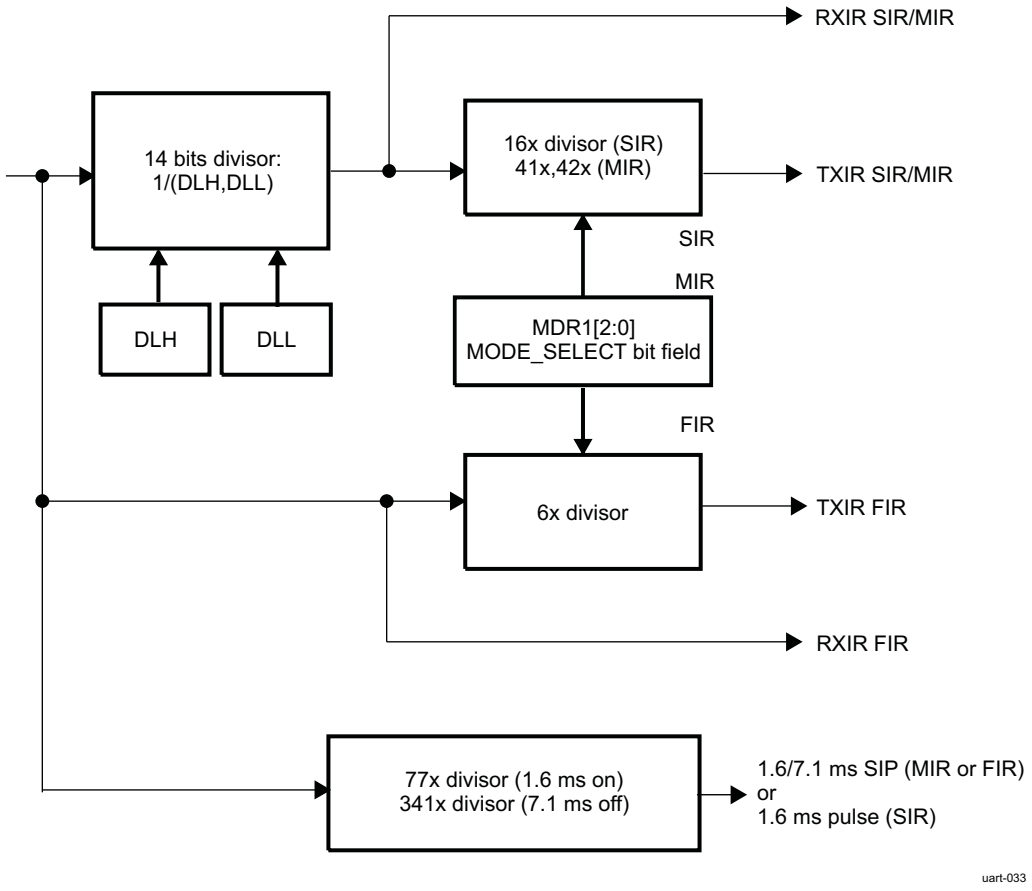
Data can be transferred both ways by the module but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware. See bit 5 in Section 19.5.26, *Auxiliary Control Register*, for a description of the logical operation. **Note:** This applies to all three modes of SIR, MIR, and FIR.

19.3.8.2.4 IrDA Clock Generation: Baud Generator

The IrDA function contains a programmable baud generator and a set of fixed dividers that divide the 48-MHz clock input down to the expected baud rate.

Figure 19-24 shows the baud rate generator and associated controls.

Figure 19-24. Baud Rate Generator



CAUTION

Before initializing or modifying clock parameter controls (UARTi.UART_DLH, UARTi.UART_DLL), MODE_SELECT=DISABLE (UARTi.UART_MDR1[2:0]) must be set to 0x7). Failure to observe this rule can result in unpredictable module behavior.

19.3.8.2.5 Choosing the Appropriate Divisor Value

Three divisor values are:

Copyright © 2011, Texas Instruments Incorporated

- SIR mode: Divisor value = Operating frequency/(16x baud rate)
- MIR mode: Divisor value = Operating frequency/(41x/42x baud rate)
- FIR mode: Divisor value = None

Table 19-28 lists the IrDA baud rate settings.

Table 19-28. IrDA Baud Rate Settings

Baud Rate	IR Mode	Baud Multiple	Encoding	DLH, DLL (Decimal)	Actual Baud Rate	Error (%)	Source Jitter (%)	Pulse Duration
2.4 kbps	SIR	16x	3/16	1250	2.4 kbps	0	0	78.1 µs
9.6 kbps	SIR	16x	3/16	312	9.6153 kbps	+0.16	0	19.5 µs
19.2 kbps	SIR	16x	3/16	156	19.231 kbps	+0.16	0	9.75 µs
38.4 kbps	SIR	16x	3/16	78	38.462 kbps	+0.16	0	4.87 µs
57.6 kbps	SIR	16x	3/16	52	57.692 kbps	+0.16	0	3.25 µs
115.2 kbps	SIR	16x	3/16	26	115.38 kbps	+0.16	0	1.62 µs
0.576 Mbps	MIR	41x/42x	1/4	2	0.5756 Mbps(1)	0	+1.63/–0.80	416 ns
1.152 Mbps	MIR	41x/42x	1/4	1	1.1511 Mbps(1)	0	+1.63/–0.80	208 ns
4 Mbps	FIR	6x	4 PPM	–	4 Mbps	0	0	125 ns

NOTE: Baud rate error and source jitter table values do not include 48-MHz reference clock error and jitter.

19.3.8.2.6 IrDA Data Formatting

The methods described in this section apply to all IrDA modes (SIR, MIR, and FIR).

19.3.8.2.6.1 IR RX Polarity Control

The UARTi.UART_MDR2[6] IRRXINVERT bit provides the flexibility to invert the uarti_rx_irrx pin in the UART to ensure that the protocol at the output of the transceiver has the same polarity at module level. By default, the uarti_rx_irrx pin is inverted because most transceivers invert the IR receive pin.

19.3.8.2.6.2 IrDA Reception Control

The module can transmit and receive data, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware.

Operation of the uarti_rx_irrx input can be disabled by the UARTi.UART_ACREG[5] DIS_IR_RX bit.

19.3.8.2.6.3 IR Address Checking

In all IR modes, when address checking is enabled, only frames intended for the device are written to the RX FIFO. This restriction avoids receiving frames not meant for this device in a multipoint infrared environment. It is possible to program two frame addresses that the UART IrDA receives, with the UARTi.UART_XON1_ADDR1[7:0] XON_WORD1 and UARTi.UART_XON2_ADDR2[7:0] XON_WORD2 bit fields.

Setting the UART_EFR[0] bit to 1 selects address1 checking. Setting the UART_EFR[1] bit to 1 selects address2 checking. Setting the UART_EFR[1:0] bit field to 0 disables all address checking operations. If both bits are set, the incoming frame is checked for private and public addresses.

If address checking is disabled, all received frames write to the RX FIFO.

19.3.8.2.6.4 Frame Closing

A transmission frame can be terminated in two ways:

Copyright © 2011, Texas Instruments Incorporated

- Frame-length method: Set the UARTi.UART_MDR1[7] FRAME_END_MODE bit to 0. The MPU writes the value of the frame length to the UARTi.UART_TXFLH and UARTi.UART_TXFLL registers. The device automatically attaches end flags to the frame when the number of bytes transmitted equals the value of the frame length.
- Set-EOT bit method: Set the FRAME_END_MODE bit to 1. The MPU writes 1 to the UARTi.UART_ACREG[0] EOT bit just before it writes the last byte to the TX FIFO. When the MPU writes the last byte to the TX FIFO, the device internally sets the tag bit for that character in the TX FIFO. As the TX state-machine reads data from the TX FIFO, it uses this tag-bit information to attach end flags and correctly terminate the frame.

19.3.8.2.6.5 Store and Controlled Transmission

In store and controlled transmission (SCT) mode, the MPU starts writing data to the TX FIFO. Then, after writing a part of a frame (for a bigger frame) or an entire frame (a small frame; that is, a supervisory frame), the MPU writes 1 to the UARTi.UART_ACREG[2] SCTX_EN bit (deferred TX start) to start transmission.

SCT mode is enabled by setting the UARTi.UART_MDR1[5] SCT bit to 1. This transmission method differs from normal mode, in which data transmission starts immediately after data is written to the TX FIFO. SCT mode is useful for sending short frames without TX underrun.

19.3.8.2.6.6 Error Detection

When the UARTi.UART_LSR register is read, the UARTi.UART_LSR[4:2] bit field reflects the error bits [FL, CRC, ABORT] of the frame at the top of the STATUS FIFO (the next frame status to be read).

The error is triggered by an interrupt (for IrDA mode interrupts, see Table 19-12). The STATUS FIFO must be read until empty (a maximum of eight reads is required).

19.3.8.2.6.7 Underrun During Transmission

Underrun during transmission occurs when the TX FIFO is empty before the end of the frame is transmitted. When underrun occurs, the device closes the frame with end flags but attaches an incorrect CRC value. The receiving device detects a CRC error and discards the frame; it can then ask for a retransmission.

Underrun also causes an internal flag to be set, which disables additional transmissions. Before the next frame can be transmitted, the MPU must:

- Reset the TX FIFO.
- Read the UARTi.UART_RESUME register, which clears the internal flag.

This function can be disabled by the UARTi.UART_ACREG[4] DIS_TX_UNDERRUN bit, compensated by the extension of the stop-bit in transmission if the TX FIFO is empty.

19.3.8.2.6.8 Overrun During Receive

Overrun during receive for the IrDA mode has the same function as that for the UART mode (see Section 19.3.8.1.3.6, *Overrun During Receive*).

19.3.8.2.6.9 Status FIFO

In IrDA modes, a status FIFO records the received frame status. When a complete frame is received, the length of the frame and the error bits associated with the frame are written to the status FIFO.

Reading the UARTi.UART_SFREGH[3:0] MSB and UARTi.UART_SFREGL[3:0] (LSB) bit fields obtains the frame length. The frame error status is read in the UARTi.UART_SFLSR register. Reading the UARTi.UART_SFLSR register increments the status FIFO read pointer. Because the status FIFO is eight entries deep, it can hold the status of eight frames.

The MPU uses the frame-length information to locate the frame boundary in the received frame data. The MPU can screen bad frames using the error status information and can later request the sender to resend only the bad frames.

Copyright © 2011, Texas Instruments Incorporated

This status FIFO can be used effectively in DMA mode because the MPU must be interrupted only when the programmed status FIFO trigger level is reached, not each time a frame is received.

19.3.8.2.7 SIR Mode Data Formatting

This section provides specific instructions for SIR mode programming.

19.3.8.2.7.1 Abort Sequence

The transmitter can prematurely close a frame (abort) by sending the sequence 0x7DC1. The abort pattern closes the frame without a CRC field or an ending flag.

A transmission frame can be aborted by setting the UARTi.UART_ACREG[1] ABORT_EN bit to 1. When this bit is set to 1, 0x7D and 0xC1 are transmitted and the frame is not terminated with CRC or stop flags.

When a 0x7D character followed immediately by a 0xC1 character is received without transparency, the receiver treats a frame as an aborted frame.

CAUTION

When the TX FIFO is not empty and the UARTi.UART_MDR1[5] SCT bit is set to 1, the UART IrDA starts a new transfer with data of a previous frame when the aborted frame is sent. Therefore, the TX FIFO must be reset before sending an aborted frame.

19.3.8.2.7.2 Pulse Shaping

SIR mode supports the 3/16 or the 1.6-µs pulse duration methods in receive and transmit. The UARTi.UART_ACREG[7] PULSE_TYPE bit selects the pulse width method in the transmit mode.

19.3.8.2.7.3 SIR Free Format Programming

The SIR FF mode is selected by setting the module in the UART mode (UARTi.UART_MDR1[2:0] MODE_SELECT = 0x0) and the UARTi.UART_MDR2[3] UART_PULSE bit to 1 to allow pulse shaping.

Because the bit format stays the same, some UART mode configuration registers must be set at specific values:

- UARTi.UART_LCR[1:0] CHAR_LENGTH bit field = 0x3 (8 data bits)
- UARTi.UART_LCR[2] NB_STOP bit = 0x0 (1 stop-bit)
- UARTi.UART_LCR[3] PARITY_EN bit = 0x0 (no parity)

The UART mode interrupts are used for the SIR FF mode, but many are not relevant (XOFF, RTS, CTS, modem status register, etc.).

19.3.8.2.8 MIR and FIR Mode Data Formatting

This section describes common instructions for FIR and MIR mode programming.

At the end of a frame reception, the MPU reads the line status register (UARTi.UART_LSR) to detect errors in the received frame.

When the UARTi.UART_MDR1[6] SIP_MODE bit is set to 1, the TX state-machine always sends one SIP at the end of a transmission frame. However, when the SIP_MODE bit is set to 0, SIP transmission depends on the UARTi.UART_ACREG[3] SEND_SIP bit.

The MPU can set the SEND_SIP bit at least once every 500 ms. The advantage of this approach over the default approach is that the TX state-machine does not have to send the SIP at the end of each frame, thus reducing the overhead required.

19.3.8.3 CIR Mode

In consumer infrared mode, the infrared operation is designed to function as a programmable (universal) remote control. By setting the MDR1 register, the UART can be set to CIR mode in the same way as the other IrDA modes are set using the MDR1 register.

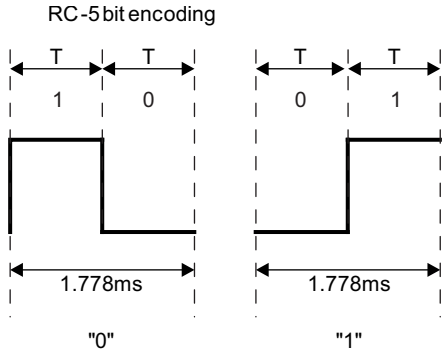
The CIR mode uses a variable pulse width modulation technique (based on multiples of a programmable T period) to encompass the various formats of infrared encoding for remote control applications. The CIR logic is to transmit and receive data packets according to the user definable frame structure and packet content.

19.3.8.3.1 Consumer IR Encoding

There are two distinct methods of encoding for remote control applications. The first uses time extended bit forms i.e. a variable pulse distance (or duration) whereby the difference between a logic one and logic zero is the length of the pulse width; and the second is the use of a bi-phase where the encoding of the logic zero and one is in the change of signal level from 1→0 or 0→1 respectively. Japanese manufacturers tend to favor the use of pulse duration encoding whereas European manufacturers favor the use of bi-phase encoding.

The CIR mode is designed to use a completely flexible free format encoding where a digit ‘1’ from the TX/RX FIFO is to be transmitted/received as a modulated pulse with duration T. Equally, a ‘0’ is to be transmitted/received as a blank duration T. The protocol of the data is to be constructed and deciphered by the host CPU. For example, the RC-5 protocol using Manchester encoding can be emulated as using a “01” pair for one and “10” pair for a zero.

Figure 19-25. RC-5 Bit Encoding

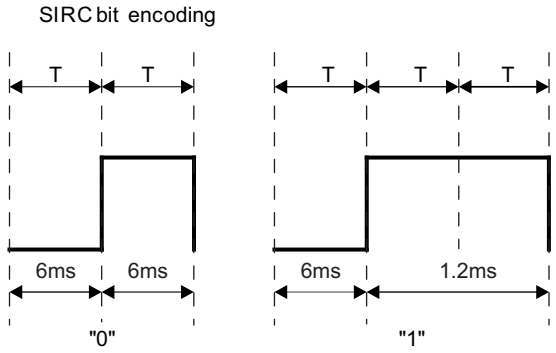


Since the CIR mode logic does not impose a fixed format for infrared packets of data, the CPU software is at liberty to define the format through the use of simple data structures that will then be modulated into an industry standard, such as RC5 or SIRC. To send a sequence of “0101” in RC5, the host software must write an eight bit binary character of “10011001” to the data TX FIFO of the UART.

For SIRC, the modulation length (i.e. multiples of T) is the method to distinguish between a “1” or a “0”. The following SIRC digits show the difference in encoding between this and RC5 for example. Note: the pulse width is extended for “1” digits.

Copyright © 2011, Texas Instruments Incorporated

Figure 19-26. SIRC Bit Encoding



To construct comprehensive packets that constitute remote control commands, the host software must combine a number of eight bit data characters in a sequence that follows one of the universally accepted formats. For illustrative purposes, a standard RC5 frame is described below (the SIRC format follows this). Each of the above fields in RC-5 can be considered as two T pulses (digital bits) from the TX and RX FIFOs.

The standard RC5 format as seen by the UART_IrDA in CIR mode.

Figure 19-27. RC-5 Standard Packet Format

S1	S2	T	A4	A3	A2	A1	A0	C5	C4	C3	C2	C1	C0

Where:

S1, S2: Start bits (always 1)

T: Toggle bit

A4–A0: Address (or system) bits

C5–C0: Command bits

The toggle bit T changes each time a new command is transmitted to allow detection of pressing the same key twice (or effectively receiving the same data from the host consecutively). Since a code is being sent as long as the CPU transmits characters to the UART for transmission, a brief delay in the transmission of the same command would be detected by the use of the toggle bit. The address bits define the machine or device that the Infrared transmission is intended for and the command defines the operation.

To accommodate an extended RC5 format, the S2 bit is replaced by a further command bit (C6) that allows the command range to increase to 7-bits. This format is known as the extended RC-5 format.

The SIRC encoding uses the duration of modulation for mark and space; hence the duration of data bits inside the standard frame length will vary depending upon the logic 1 content. The packet format and bit encoding is illustrated below. There is one start bit of two milliseconds and control codes followed by data that constitute the whole frame.

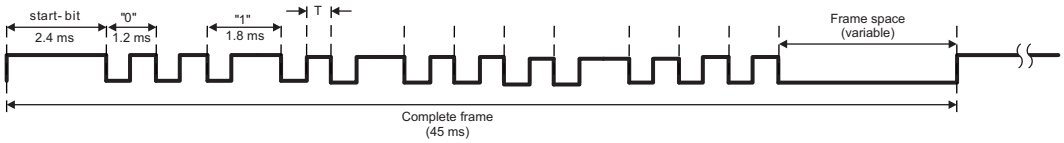
Figure 19-28. SIRC Packet Format

S	C0	C1	C2	C3	C4	C5	C6	D0	D1	D2	D3	D4

It should be noted that the encoding must take a standard duration but the contents of the data may vary. This implies that the control software for emitting and receiving data packets must exercise a scheme of inter-packet delay, where the emission of successive packets can only be done after a real time delay has expired.

Copyright © 2011, Texas Instruments Incorporated

Figure 19-29. SIRC Bit Transmission Example

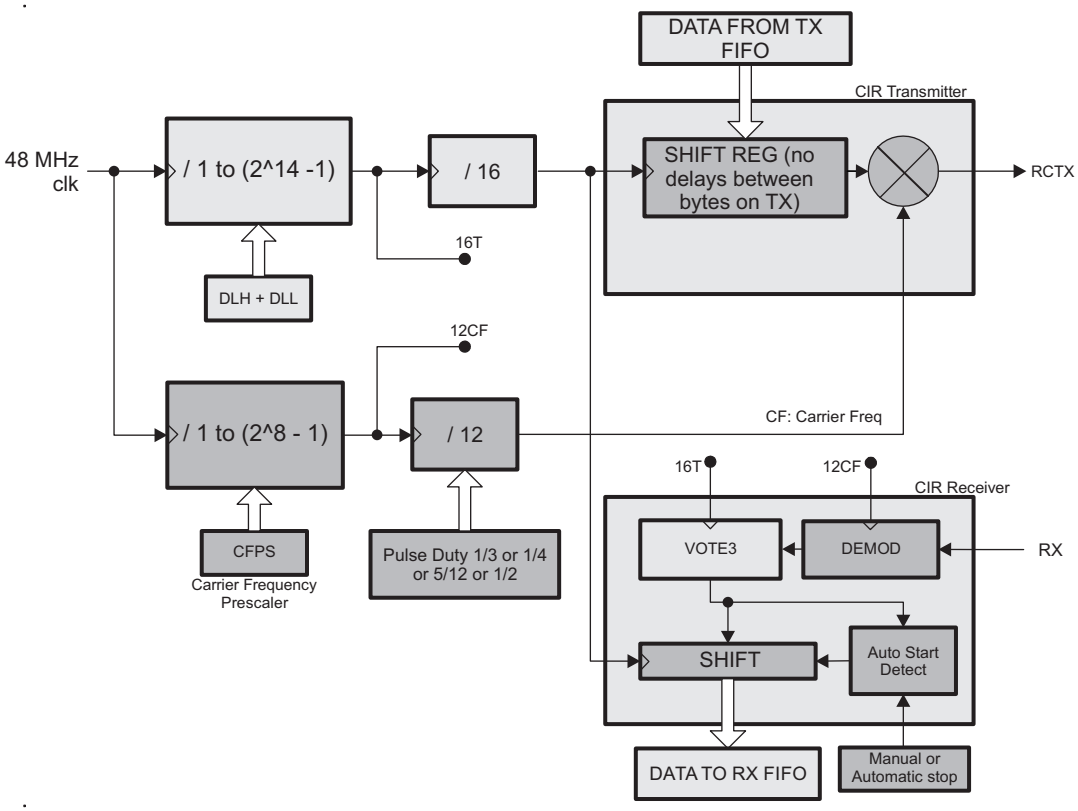


It is beyond the scope of this document to describe all encoding methods and techniques, the previous information was provided to illustrate the consideration required to employ different encoding methods for different industry standard protocols. The user should refer to industry standard documentation for specific methods of encoding and protocol usage.

19.3.8.3.2 CIR Mode Operation

Depending on the encoding method (variable pulse distance / bi-phase), the LH should develop a data structure that combines the 1 and 0 with a T period in order to encode the complete frame to transmit. This can then be transmitted to the infrared output with a method of modulation shown in the following diagram.

Figure 19-30. CIR Mode Block Components



Copyright © 2011, Texas Instruments Incorporated

In transmission, the LH software must exercise an element of real time control for transmitting data packets; they must each be emitted at a constant delay from the start bits of each of the individual packets which means when sending a series of packets, the packet to packet delay must respect a specific delay. To control this delay 2 methods can be used:

- By filling the TX FIFO with a number of zero bit which is transmitted with a T period.
- By using an external system timer which controls the delay either between each start of frame or between the end of a frame and the start of the next one. This can be performed:
  - By controlling the start of the frame through the configuration register MDR1[5] and ACREG[2] depending on the timer status (in case of control the delay between each start of frame).
  - By using the TX_STATUS interrupt IIR[5] to pre-load the next frame in the TX FIFO and to control the start of the timer (in case of control the delay between end of frame and start of next frame).

In reception, there are two ways to stop it :

- The LH can disable the reception by setting the ACREG[5] to 1 when it considers that the reception is finished because a large number of 0 has been received. To receive a new frame, the ACREG[5] must be set to 0.
- A specific mechanism, depending on the value set in the BOF length register (EBLR), allows for automatically stopping the reception. If the value set in the EBLR register is different than 0, this features is enabled and count a number of bit received at 0. When the counter achieves the value defined in the EBLR register, the reception is automatically stopped and RX_STOP_IT (IIR[2]) is set. When a 1 is detected on the RCRX pin, the reception is automatically enabled.

Note: There's a limitation when receiving data in UART CIR mode. The IrDA transceivers on the market have a common characteristic that shrinks the hold time of the received modulation pulse. The UART filtering schema on receiving is based on the same encoding mechanism used in transmission.

For the following scenario:

- Shift register period: 0.9 us
- Modulation frequency: 36 Khz
- Duty cycle: 1/4 of a modulation frequency period

The data sent in these conditions would look like 7us pulses within 28us period. The UART expects to receive similar incoming data on receive, but available transceiver timing characteristics typically send 2us modulated pulses. Those will be filtered out and RX FIFO won't receive any data.

This does not affect UART CIR mode in transmission.

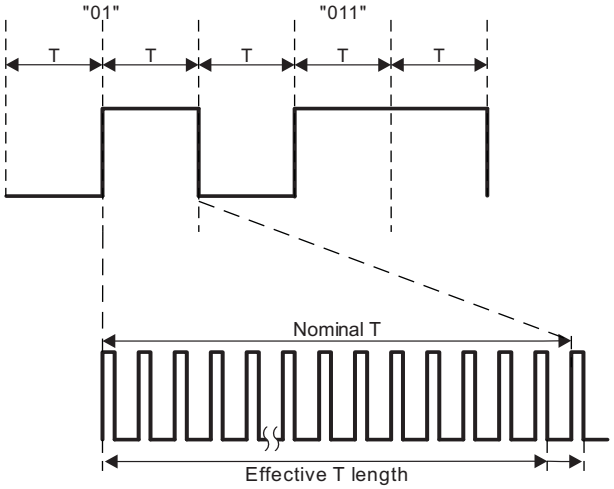
Note: The CIR RX demodulation can be bypassed by setting the MDR3[0] register bit.

19.3.8.3.3 Carrier Modulation

Looking closer at the actual modulation pulses of the infrared data stream, it should be noted that each modulated pulse that constitutes a digit is in fact a train of on/off pulses.

Copyright © 2011, Texas Instruments Incorporated

Figure 19-31. CIR Pulse Modulation



A minimum of 4 modulation pulses per bit is required by the module.

Based on the requested modulation frequency, the CFPS register must be set with the correct dividing value to provide the more accurate pulse frequency:

Dividing value = (FCLK/12)/MODfreq

Where FCLK = System clock frequency (48 MHz)

12 = real value of BAUD multiple

MODfreq = Effective frequency of the modulation (MHz)

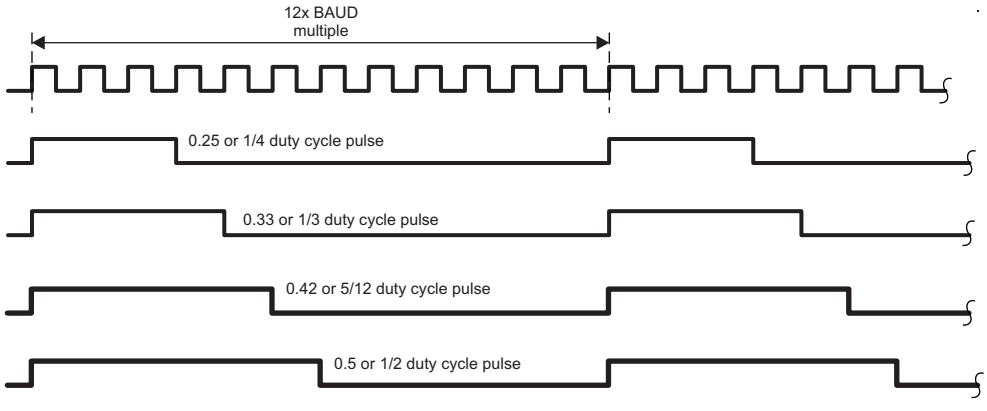
Example: For a targeted modulation frequency of 36 kHz, the CFPS value must be set to 111 in decimal which provide an modulation frequency of 36.04 kHz.

Note: The CFPS register is to start with a reset value of 105 (decimal) which translates to a frequency of 38.1 kHz.

The duty cycle of these pulses is user defined by the pulse duty register bits in the MDR2 configuration register.

MDR2[5:4]	Duty Cycle (High Level)
00	1/4
01	1/3
10	5/12
11	1/2

Figure 19-32. CIR Modulation Duty Cycle



Copyright © 2011, Texas Instruments Incorporated

The transmission logic ensures that all pulses are transmitted completely; i.e., there is no cut off of any pulses during its transmission. Furthermore, while transmitting continuous bytes back-to-back, no delay is inserted between two transmitted bytes. **Note:** The CIR RX demodulation can be bypassed by setting the MDR3[0] register bit. This bit will not affect the transmission modulation.

Copyright © 2011, Texas Instruments Incorporated

19.3.8.3.4 Frequency Divider Values

The data transferred is a succession of pulse with a T period. Depending on the standards used, the T period is defined through the DLL and DLH registers which defined the value to divide the functional clock (48 MHz):

Dividing value = (FCLK/16)/Tfreq

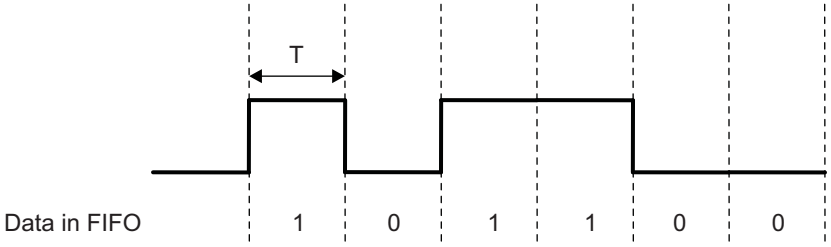
Where FCLK = System clock frequency (48 MHz)

16 = real value of BAUD multiple

Tfreq = Effective frequency of the T pulse (MHz)

In an example case using a variable pulse duration definitions:

Figure 19-33. Variable Pulse Duration Definitions



For a logical “1”, the pulse duration is equal to 2T and for a logical “0”, it’s equal to 4T.

If T =0.56 ms, the value coded into the DLH and DLL register must be 1680 in decimal.

19.4 UART/IrDA/CIR Basic Programming Model

19.4.1 UART Programming Model

19.4.1.1 Quick Start

This section describes the procedure for operating the UART with FIFO and DMA or interrupts. This three-part procedure ensures the quick start of the UART. It does not cover every UART feature.

The first programming model covers software reset of the UART. The second programming model describes FIFO and DMA configuration. The last programming model describes protocol, baud rate, and interrupt configuration.

NOTE: Each programming model can be used independently of the other two; for instance, reconfiguring the FIFOs and DMA settings only.

Each programming model can be executed starting from any UART register access mode (register modes, submodes, and other register dependencies). However, if the UART register access mode is known before executing the programming model, some steps that enable or restore register access are optional. For more information, see Section 19.3.7.1, *Register Access Modes*.

19.4.1.1.1 Software Reset

To clear the UART registers, perform the following steps:

1. Initiate a software reset:
   Set the UARTi.UART_SYSC[1] SOFTRESET bit to 1.
2. Wait for the end of the reset operation:
   Poll the UARTi.UART_SYSS[0] RESETDONE bit until it equals 1.

19.4.1.1.2 FIFOs and DMA Settings

To enable and configure the receive and transmit FIFOs and program the DMA mode, perform the following steps:

1. Switch to register configuration mode B to access the UARTi.UART_EFR register:
   (a) Save the current UARTi.UART_LCR register value.
   (b) Set the UARTi.UART_LCR register value to 0x00BF.
2. Enable register submode TCR_TLR to access the UARTi.UART_TLR register (part 1 of 2):
   (a) Save the UARTi.UART_EFR[4] ENHANCED_EN value.
   (b) Set the UARTi.UART_EFR[4] ENHANCED_EN bit to 1.
3. Switch to register configuration mode A to access the UARTi.UART_MCR register:
   Set the UARTi.UART_LCR register value to 0x0080.
4. Enable register submode TCR_TLR to access the UARTi.UART_TLR register (part 2 of 2):
   (a) Save the UARTi.UART_MCR[6] TCR_TLR value.
   (b) Set the UARTi.UART_MCR[6] TCR_TLR bit to 1.
5. Enable the FIFO; load the new FIFO triggers (part 1 of 3) and the new DMA mode (part 1 of 2):
   Set the following bits to the desired values:
   - UARTi.UART_FCR[7:6] RX_FIFO_TRIG
   - UARTi.UART_FCR[5:4] TX_FIFO_TRIG
   - UARTi.UART_FCR[3] DMA_MODE
   - UARTi.UART_FCR[0] FIFO_ENABLE (0: Disable the FIFO; 1: Enable the FIFO)

Copyright © 2011, Texas Instruments Incorporated

NOTE: The UARTi.UART_FCR register is not readable.

6. Switch to register configuration mode B to access the UARTi.UART_EFR register:
   Set the UARTi.UART_LCR register value to 0x00BF.
7. Load the new FIFO triggers (part 2 of 3):
   Set the following bits to the desired values:
   - UARTi.UART_TLR[7:4] RX_FIFO_TRIG_DMA
   - UARTi.UART_TLR[3:0] TX_FIFO_TRIG_DMA
8. Load the new FIFO triggers (part 3 of 3) and the new DMA mode (part 2 of 2):
   Set the following bits to the desired values:
   - UARTi.UART_SCR[7] RX_TRIG_GRANU1
   - UARTi.UART_SCR[6] TX_TRIG_GRANU1
   - UARTi.UART_SCR[2:1] DMA_MODE_2
   - UARTi.UART_SCR[0] DMA_MODE_CTL
9. Restore the UARTi.UART_EFR[4] ENHANCED_EN value saved in Step 2a.
10. Switch to register configuration mode A to access the UARTi.UART_MCR register:
    Set the UARTi.UART_LCR register value to 0x0080.
11. Restore the UARTi.UART_MCR[6] TCR_TLR value saved in Step 4a.
12. Restore the UARTi.UART_LCR value saved in Step 1a.

Triggers are used to generate interrupt and DMA requests. See Section 19.3.6.1.1, *Transmit FIFO Trigger,* to choose the following values:

- UARTi.UART_FCR[5:4] TX_FIFO_TRIG
- UARTi.UART_TLR[3:0] TX_FIFO_TRIG_DMA
- UARTi.UART_SCR[6] TX_TRIG_GRANU1

Triggers are used to generate interrupt and DMA requests. See Section 19.3.6.1.2, *Receive FIFO Trigger*, to choose the following values:

- UARTi.UART_FCR[7:6] RX_FIFO_TRIG
- UARTi.UART_TLR[7:4] RX_FIFO_TRIG_DMA
- UARTi.UART_SCR[7] RX_TRIG_GRANU1

DMA mode enables DMA requests. See Section 19.3.6.4, *FIFO DMA Mode Operation*, to choose the following values:

- UARTi.UART_FCR[3] DMA_MODE
- UARTi.UART_SCR[2:1] DMA_MODE_2
- UARTi.UART_SCR[0] DMA_MODE_CTL

19.4.1.1.3 Protocol, Baud Rate, and Interrupt Settings

To program the protocol, baud rate, and interrupt settings, perform the following steps:

1. Disable UART to access the UARTi.UART_DLL and UARTi.UART_DLH registers:
   Set the UARTi.UART_MDR1[2:0] MODE_SELECT bit field to 0x7.
2. Switch to register configuration mode B to access the UARTi.UART_EFR register:
   Set the UARTi.UART_LCR register value to 0x00BF.
3. Enable access to the UARTi.UART_IER[7:4] bit field:
   (a) Save the UARTi.UART_EFR[4] ENHANCED_EN value.
   (b) Set the UARTi.UART_EFR[4] ENHANCED_EN bit to 1.
4. Switch to register operational mode to access the UARTi.UART_IER register:
   Set the UARTi.UART_LCR register value to 0x0000.

Copyright © 2011, Texas Instruments Incorporated

5. Clear the UARTi.UART_IER register (set the UARTi.UART_IER[4] SLEEP_MODE bit to 0 to change the UARTi.UART_DLL and UARTi.UART_DLH registers). Set the UARTi.UART_IER register value to 0x0000.
6. Switch to register configuration mode B to access the UARTi.UART_DLL and UARTi.UART_DLH registers:

   Set the UARTi.UART_LCR register value to 0x00BF.
7. Load the new divisor value:

   Set the UARTi.UART_DLL[7:0] CLOCK_LSB and UARTi.UART_DLH[5:0] CLOCK_MSB bit fields to the desired values.
8. Switch to register operational mode to access the UARTi.UART_IER register:

   Set the UARTi.UART_LCR register value to 0x0000.
9. Load the new interrupt configuration (0: Disable the interrupt; 1: Enable the interrupt):

   Set the following bits to the desired values:
   - UARTi.UART_IER[7] CTS_IT
   - UARTi.UART_IER[6] RTS_IT
   - UARTi.UART_IER[5] XOFF_IT
   - UARTi.UART_IER[4] SLEEP_MODE
   - UARTi.UART_IER[3] MODEM_STS_IT
   - UARTi.UART_IER[2] LINE_STS_IT
   - UARTi.UART_IER[1] THR_IT
   - UARTi.UART_IER[0] RHR_IT
10. Switch to register configuration mode B to access the UARTi.UART_EFR register:

    Set the UARTi.UART_LCR register value to 0x00BF.
11. Restore the UARTi.UART_EFR[4] ENHANCED_EN value saved in Step 3a.
12. Load the new protocol formatting (parity, stop-bit, character length) and switch to register operational mode:

    Set the UARTi.UART_LCR[7] DIV_EN bit to 0.

    Set the UARTi.UART_LCR[6] BREAK_EN bit to 0.

    Set the following bits to the desired values:
    - UARTi.UART_LCR[5] PARITY_TYPE_2
    - UARTi.UART_LCR[4] PARITY_TYPE_1
    - UARTi.UART_LCR[3] PARITY_EN
    - UARTi.UART_LCR[2] NB_STOP
    - UARTi.UART_LCR[1:0] CHAR_LENGTH
13. Load the new UART mode:

    Set the UARTi.UART_MDR1[2:0] MODE_SELECT bit field to the desired value.

See Section 19.3.8.1.2, *Choosing the Appropriate Divisor Value*, to choose the following values:

- UARTi.UART_DLL[7:0] CLOCK_LSB
- UARTi.UART_DLH[5:0] CLOCK_MSB
- UARTi.UART_MDR1[2:0] MODE_SELECT

See Section 19.3.8.1.3.1, *Frame Formatting*, to choose the following values:

- UARTi.UART_LCR[5] PARITY_TYPE_2
- UARTi.UART_LCR[4] PARITY_TYPE_1
- UARTi.UART_LCR[3] PARITY_EN
- UARTi.UART_LCR[2] NB_STOP
- UARTi.UART_LCR[1:0] CHAR_LENGTH

19.4.1.2 Hardware and Software Flow Control Configuration

This section describes the programming steps to enable and configure hardware and software flow control. Hardware and software flow control cannot be used at the same time.

NOTE: Each programming model can be executed starting from any UART register access mode (register modes, submodes, and other register dependencies). However, if the UART register access mode is known before executing the programming model, some steps that enable or restore register access are optional. For more information, see Section 19.3.7.1, *Register Access Modes*.

19.4.1.2.1 Hardware Flow Control Configuration

To enable and configure hardware flow control, perform the following steps:

1. Switch to register configuration mode A to access the UARTi.UART_MCR register:
   (a) Save the current UARTi.UART_LCR register value.
   (b) Set the UARTi.UART_LCR register value to 0x0080.
2. Enable register submode TCR_TLR to access the UARTi.UART_TCR register (part 1 of 2):
   (a) Save the UARTi.UART_MCR[6] TCR_TLR value.
   (b) Set the UARTi.UART_MCR[6] TCR_TLR bit to 1.
3. Switch to register configuration mode B to access the UARTi.UART_EFR register:
   Set the UARTi.UART_LCR register value to 0x00BF.
4. Enable register submode TCR_TLR to access the UARTi.UART_TCR register (part 2 of 2):
   (a) Save the UARTi.UART_EFR[4] ENHANCED_EN value.
   (b) Set the UARTi.UART_EFR[4] ENHANCED_EN bit to 1.
5. Load the new start and halt trigger values for hardware flow control:
   Set the following bits to the desired values:
   - UARTi.UART_TCR[7:4] AUTO_RTS_START
   - UARTi.UART_TCR[3:0] AUTO_RTS_HALT
6. Enable or disable receive and transmit hardware flow control mode and restore the UARTi.UART_EFR[4] ENHANCED_EN value saved in Step 4a.
   Set the following bits to the desired values:
   - UARTi.UART_EFR[7] AUTO_CTS_EN (0: Disable; 1: Enable)
   - UARTi.UART_EFR[6] AUTO_RTS_EN (0: Disable; 1: Enable)

   Restore the UARTi.UART_EFR[4] ENHANCED_EN bit to the saved value.
7. Switch to register configuration mode A to access the UARTi.UART_MCR register:
   Set the UARTi.UART_LCR register value to 0x0080.
8. Restore the UARTi.UART_MCR[6] TCR_TLR value saved in Step 2a.
9. Restore the UARTi.UART_LCR value saved in Step 1a.

See Section 19.3.8.1.3.2, *Hardware Flow Control*, to choose the following values:

- UARTi.UART_EFR[7] AUTO_CTS_EN
- UARTi.UART_EFR[6] AUTO_RTS_EN
- UARTi.UART_TCR[7:4] AUTO_RTS_START
- UARTi.UART_TCR[3:0] AUTO_RTS_HALT

19.4.1.2.2 Software Flow Control Configuration

To enable and configure software flow control, perform the following steps:

1. Switch to register configuration mode B to access the UARTi.UART_EFR register.

Copyright © 2011, Texas Instruments Incorporated

(a) Save the current UARTi.UART_LCR register value.

(b) Set the UARTi.UART_LCR register value to 0x00BF.

2. Enable register submode XOFF to access the UARTi.UART_XOFF1 and UARTi.UART_XOFF2 registers:

   (a) Save the UARTi.UART_EFR[4] ENHANCED_EN value.

   (b) Set the UARTi.UART_EFR[4] ENHANCED_EN bit to 0.

3. Load the new software flow control characters:

   Set the following bits to the desired values:

   - UARTi.UART_XON1_ADDR1[7:0] XON_WORD1
   - UARTi.UART_XON2_ADDR2[7:0] XON_WORD2
   - UARTi.UART_XOFF1[7:0] XOFF_WORD1
   - UARTi.UART_XOFF2[7:0] XOFF_WORD2

4. Enable access to the UARTi.UART_MCR[7:5] bit field and enable register submode TCR_TLR to access the UARTi.UART_TCR register (part 1 of 2):

   Set the UARTi.UART_EFR[4] ENHANCED_EN bit to 1.

5. Switch to register configuration mode A to access the UARTi.UART_MCR register:

   Set the UARTi.UART_LCR register value to 0x0080.

6. Enable register submode TCR_TLR to access the UARTi.UART_TCR register (part 2 of 2) and enable or disable XON any function:

   (a) Save the UARTi.UART_MCR[6] TCR_TLR value.

   (b) Set the UARTi.UART_MCR[6] TCR_TLR bit to 1.

   (c) Set the UARTi.UART_MCR[5] XON_EN bit to the desired value (0: Disable; 1: Enable).

7. Switch to register configuration mode B to access the UARTi.UART_EFR register:

   Set the UARTi.UART_LCR register value to 0x00BF.

8. Load the new start and halt trigger values for software flow control:

   Set the following bits to the desired values:

   - UARTi.UART_TCR[7:4] AUTO_RTS_START
   - UARTi.UART_TCR[3:0] AUTO_RTS_HALT

9. Enable or disable special character function and load the new software flow control mode and restore the UARTi.UART_EFR[4] ENHANCED_EN value saved in Step 2a:

   Set the following bits to the desired values:

   - UARTi.UART_EFR[5] SPEC_CHAR (0: Disable; 1: Enable)
   - UARTi.UART_EFR[3:0] SW_FLOW_CONTROL

   Restore the UARTi.UART_EFR[4] ENHANCED_EN bit to the saved value.

10. Switch to register configuration mode A to access the UARTi.UART_MCR register:

    Set the UARTi.UART_LCR register value to 0x0080.

11. Restore the UARTi.UART_MCR[6] TCR_TLR bit value saved in Step 6a.

12. Restore the UARTi.UART_LCR value saved in Step 1a.

See Section 19.3.8.1.3.3, *Software Flow Control*, to choose the following values:

- UARTi.UART_EFR[5] SPEC_CHAR
- UARTi.UART_EFR[3:0] SW_FLOW_CONTROL
- UARTi.UART_TCR[7:4] AUTO_RTS_START
- UARTi.UART_TCR[3:0] AUTO_RTS_HALT
- UARTi.UART_XON1_ADDR1[7:0] XON_WORD1
- UARTi.UART_XON2_ADDR2[7:0] XON_WORD2
- UARTi.UART_XOFF1[7:0] XOFF_WORD1

19.4.2 IrDA Programming Model

19.4.2.1 SIR Mode

19.4.2.1.1 Receive

The following programming model explains how to program the module to receive an IrDA frame with parity forced to 1, baud rate = 112.5KB, FIFOs disabled, 2 stop-bits, and 8-bit word length:

1. Disable the UART before accessing the UARTi.UART_DLL and UARTi.UART_DLH registers:
   Set the UARTi.UART_MDR1[2:0] MODE_SELECT bit field to 0x7.
2. Grant access to the UART_DLL and UART_DLH registers (the UART_LCR[7] DIV_EN bit = 1):
   UARTi.UART_LCR = 0x80 (Data format is unaffected by the use and settings of the UARTi.UART_LCR register in IrDA mode.)
3. Load the new baud rate (115.2 kbps):
   UARTi.UART_DLL = 0x1A
   UARTi.UART_DLH = 0x00
4. Set SIR mode:
   UARTi.UART_MDR1[2:0] MODE_SELECT = 0x1
5. Disable access to the UART_DLL and UART_DLH registers and switch to register operational mode:
   UARTi.UART_LCR = 0x00.
6. Optional: Enable the RHR interrupt:
   UARTi.UART_IER[0] RHR_IT = 0x1

19.4.2.1.2 Transmit

The following programming model explains how to program the module to transmit an IrDA 6-byte frame with no parity, baud rate = 112.5 kbps, FIFOs disabled, 3/16 encoding, 2 stop-bits, and 7-bit word length:

1. Disable the UART before accessing the UARTi.UART_DLL and UARTi.UART_DLH registers:
   Set the UART_MDR1[2:0] MODE_SELECT bit field to 0x7.
2. Grant access to the UART_EFR register:
   UARTi.UART_LCR = 0xBF
3. Enable the enhanced features (the UART_EFR[4] ENAHNCED_EN bit = 1):
   Set the UARTi.UART_EFR register value to 0x10.
4. Grant access to the UART_DLL and UART_DLH registers (the UART_LCR[7] DIV_EN bit = 1):
   UARTi.UART_LCR = 0x80 (Data format is unaffected by the use and settings of the UARTi.UART_LCR register in IrDA mode.)
5. Load the new baud rate (115.2 kbps):
   UARTi.UART_DLL = 0x1A
   UARTi.UART_DLH = 0x00
6. Set SIR mode (the UART_MDR1[2:0] MODE_SELECT bit field = 0x1):
   UARTi.UART_MDR1 = 0x01
7. Disable access to the UART_DLL and UART_DLH registers and switch to register operational mode:
   UARTi.UART_LCR = 0x00.
8. Force DTR output to active:
   UARTi.UART_MCR[0] DTR = 1
9. Optional: Enable the THR interrupt:
   UARTi.UART_IER[1] THR_IT = 1
10. Set transmit frame length to 6 bytes:
    UARTi.UART_TXFLL = 0x06
11. Set 7 starts of frame transmission:
    UARTi.UART_EBLR = 0x08
12. Optional: Set SIR pulse width to be 1.6 us:
    UARTi.UART_ACREG[7] PULSE_TYPE = 1
13. Load the UART_THR register with the data to be transmitted.

Copyright © 2011, Texas Instruments Incorporated

19.4.2.2 MIR Mode

19.4.2.2.1 Receive

The following programming model explains how to program the module to receive an IrDA frame with no parity, baud rate = 1.152 Mpbs, and FIFOs disabled.

1. Disable the UART before accessing the UARTi.UART_DLL and UARTi.UART_DLH registers:
   Set the UARTi.UART_MDR1[2:0] MODE_SELECT bit field to 0x7.
2. Grant access to the UART_DLL and UART_DLH registers (UART_LCR[7] DIV_EN bit = 1):
   UARTi.UART_LCR = 0x80 (Data format is unaffected by the use and settings of the UARTi.UART_LCR register in IrDA mode.)
3. Load the new baud rate (1.152 Mpbs):
   UARTi.UART_DLL = 0x01
   UARTi.UART_DLH = 0x00
4. Set MIR mode:
   UARTi.UART_MDR1[2:0] MODE_SELECT = 0x4
5. Disable access to the UART_DLL and UART_DLH registers and switch to register operational mode:
   UARTi.UART_LCR = 0x00
6. Force DTR output to active (UART_MCR[0] DTR = 1):
   Force RTS output to active (UART_MCR[1] RTS = 1).
   UARTi.UART_MCR = 0x3
7. Optional: Enable the RHR interrupt:
   UARTi.UART_IER[0] RHR_IT = 1

19.4.2.2.2 Transmit

The following programming model explains how to program the module to transmit an IrDA 60-byte frame with no parity, baud rate = 1.152 Mpbs, and FIFOs disabled:

1. Disable the UART before accessing the UARTi.UART_DLL and UARTi.UART_DLH registers:
   Set the UARTi.UART_MDR1[2:0] MODE_SELECT bit field to 0x7.
2. Grant access to the UART_DLL and UART_DLH registers (UART_LCR[7] DIV_EN bit = 1):
   UARTi.UART_LCR = 0x80 (Data format is unaffected by the use and settings of the UARTi.UART_LCR register in IrDA mode.)
3. Load the new baud rate (1.152 Mpbs):
   UARTi.UART_DLL = 0x01
   UARTi.UART_DLH = 0x00
4. Set MIR mode:
   UARTi.UART_MDR1[2:0] MODE_SELECT = 0x4
5. Disable access to the UART_DLL and UART_DLH registers and switch to register operational mode:
   UARTi.UART_LCR = 0x00
6. Force DTR output to active:
   UARTi.UART_MCR[0] DTR = 1
7. Optional: Enable the THR interrupt:
   UARTi.UART_IER[1] THR_IT = 1
8. Set the frame length to 60 bytes:
   UARTi.UART_TXFLL = 0x3C
9. Optional: Transmit eight additional starts of frame (MIR mode requires two starts):
   UARTi.UART_EBLR = 0x08
10. SIP is sent at the end of transmission:
    UARTi.UART_ACREG[3] = 1
11. Load the UART_THR register with the data to be transmitted.

Copyright © 2011, Texas Instruments Incorporated

19.4.2.3 FIR Mode

19.4.2.3.1 Receive

The following programming model explains how to program the module to receive the IrDA frame with no parity, baud rate = 4 Mbps, FIFOs enabled, 8-bit word length.

1. Disable the UART before accessing the UARTi.UART_DLL and UARTi.UART_DLH registers:
   Set the UARTi.UART_MDR1[2:0] MODE_SELECT bit field to 0x7.
2. Grant access to the UART_DLL and UART_DLH registers (UART_LCR[7] DIV_EN bit = 1):
   UARTi.UART_LCR = 0x80 (Data format is unaffected by the use and settings of the UARTi.UART_LCR register in IrDA mode.)
3. FIFO clear and enable:
   UARTi.UART_FCR = 0x7 (TX/RX FIFO trigger: UART_FCR[7:6] and UART_FCR[5:4])
   UARTi.UART_LCR[7] = 0
4. Set FIR mode:
   UARTi.UART_MDR1[2:0] MODE_SELECT = 0x5
5. Set frame length:
   UARTi.UART_RXFLL = 0xA (Data + CRC + STOP)
6. Disable access to the UARTi.UART_DLL registers and UARTi.UART_DLH and switch to register operational mode:
   UARTi.UART_LCR[7] DIV_EN = 0x0
7. Optional: Enable the RHR interrupt:
   UARTi.UART_IER[0] RHR_IT = 1

19.4.2.3.2 Transmit

The following programming model explains how to program the module to transmit an IrDA 4-byte frame with no parity, baud rate = 4 Mbps, FIFOs enabled, and 8-bit word length.

1. Disable the UART before accessing the UARTi.UART_DLL and UARTi.UART_DLH registers:
   Set the UARTi.UART_MDR1[2:0] MODE_SELECT bit field to 0x7.
2. Grant access to EFR_REG:
   UARTi.UART_LCR = 0xBF
3. Enable the enhanced features (EFR_REG[4] ENAHNCED_EN = 0x1):
   UARTi.UART_EFR = 0x10
4. FIFO clear and enable:
   UARTi.UART_FCR = 0x7 (TX/RX FIFO trigger: UART_FCR[7:6] and UART_FCR[5:4]).
   UARTi.UART_LCR[7] = 0
5. Set FIR mode and enable auto-SIP mode:
   UARTi.UART_MDR1 = 0x45
6. Set frame length:
   UARTi.UART_TXFLL = 0x4
   UARTi.UART_TXFLH = 0x0
   UARTi.UART_RXFLL = 0xA (Data + CRC + STOP)
   UARTi.UART_RXFLH = 0x0
7. Force DTR output to active:
   UARTi.UART_MCR[0] DTR = 0x1
8. Optional: Enable the THR interrupt:
   UARTi.UART_IER[1] THR_IT = 0x1
9. Optional: Transmit eight additional starts of frame (MIR mode requires two starts):
   UARTi.UART_EBLR = 0x08
10. SIP is sent at the end of transmission:
    UARTi.UART_ACREG[3] = 1
11. Load the UART_THR register with the data to be transmitted.

19.5 UART Registers

Each register is selected using a combination of address and for some LCR register bit(s) setting as shown in Table 19-29. The following registers are accessible by the local host (LH) at address = module base address + address offset. The module base address is the module start address. Note that register address offsets depends upon the module address alignment at the system top level.

Table 19-29. UART Registers

Address Offset	Registers					
	LCR[7] = 0		LCR[7:0] ≠ BFh		LCR[7:0] = BFh	
	Read	Write	Read	Write	Read	Write
0h	RHR	THR	DLL	DLL	DLL	DLL
4h	IER(1)	IER(1)	DLH	DLH	DLH	DLH
8h	IIR	FCR(2)	IIR	FCR(2)	EFR	EFR

1Ch	SPR/TLR(3)	SPR/TLR(3)	SPR/TLR(3)	SPR/TLR(3)	XOFF2/TLR(3)	XOFF2/TLR(3)
20h	MDR1	MDR1	MDR1	MDR1	MDR1	MDR1
24h	MDR2	MDR2	MDR2	MDR2	MDR2	MDR2
28h	SFLSR	TXFLL	SFLSR	TXFLL	SFLSR	TXFLL
2Ch	RESUME	TXFLH	RESUME	TXFLH	RESUME	TXFLH
30h	SFREGL	RXFLL	SFREGL	RXFLL	SFREGL	RXFLL
34h	SFREGH	RXFLH	SFREGH	RXFLH	SFREGH	RXFLH
38h	BLR	BLR	UASR	-	UASR	-
3Ch	ACREG	ACREG	-	-	-	-
40h	SCR	SCR	SCR	SCR	SCR	SCR
44h	SSR	SSR[2]	SSR	SSR[2]	SSR	SSR[2]
48h	EBLR	EBLR	-	-	-	-
50h	MVR	-	MVR	-	MVR	-
54h	SYSC	SYSC	SYSC	SYSC	SYSC	SYSC
58h	SYSS	-	SYSS	-	SYSS	-
5Ch	WER	WER	WER	WER	WER	WER
60h	CFPS	CFPS	CFPS	CFPS	CFPS	CFPS

(1) In UART modes, IER[7:4] can only be written when EFR[4] = 1; in IrDA/CIR modes, EFR[4] has no impact on the access to IER[7:4].

(2) MCR[7:5] and FCR[5:4] can only be written when EFR[4] = 1.

(3) Transmission control register (TCR) and trigger level register (TLR) are accessible only when EFR[4] = 1 and MCR[6] = 1.

Copyright © 2011, Texas Instruments Incorporated

19.5.1 Receiver Holding Register (RHR)

The receiver section consists of the receiver holding register and the receiver shift register. The RHR is actually a 64-byte FIFO. The receiver shift register receives serial data from RX input. The data is converted to parallel data and moved to the RHR. If the FIFO is disabled, location zero of the FIFO is used to store the single data character.

NOTE: If an overflow occurs, the data in the RHR is not overwritten.

The receiver holding register (RHR) register is shown in Figure 19-34 and described in Table 19-30.

Figure 19-34. Receiver Holding Register (RHR)

15	8	7	0
Reserved		RHR	
R-0		R-unknown	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 19-30. Receiver Holding Register (RHR) Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reserved.
7-0	RHR	0-FFh	Receive holding register.

19.5.2 Transmit Holding Register (THR)

The transmitter section consists of the transmit holding register and the transmit shift register. The transmit holding register is a 64-byte FIFO. The MPU writes data to the THR. The data is placed in the transmit shift register where it is shifted out serially on the TX output. If the FIFO is disabled, location zero of the FIFO is used to store the data.

The transmit holding register (THR) is shown in Figure 19-35 and described in Table 19-31.

Figure 19-35. Transmit Holding Register (THR)

19.5.3 Interrupt Enable Register (IER) - UART Mode

The interrupt enable register (IER) can be programmed to enable/disable any interrupt. There are seven types of interrupt in this mode: receiver error, RHR interrupt, THR interrupt, XOFF received and $\overline{CTS}$/$\overline{RTS}$ change of state from low to high. Each interrupt can be enabled/disabled individually. There is also a sleep mode enable bit. The UART interrupt enable register (IER) is shown in Figure 19-36 and described in Table 19-32.

Figure 19-36. UART Interrupt Enable Register (IER)

15							8

Table 19-32. UART Interrupt Enable Register (IER) Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reserved.
7	CTSIT		Can be written only when EFR[4] = 1.
		0	Disables the $\overline{CTS}$ interrupt.
		1	Enables the $\overline{CTS}$ interrupt.
6	RTSIT		Can be written only when EFR[4] = 1.
		0	Disables the $\overline{RTS}$ interrupt.
		1	Enables the $\overline{RTS}$ interrupt.
5	XOFFIT		Can be written only when EFR[4] = 1.
		0	Disables the XOFF interrupt.
		1	Enables the XOFF interrupt.
4	SLEEPMODE		Can be only written when EFR[4] = 1.
		0	Disables sleep mode.
		1	Enables sleep mode (stop baud rate clock when the module is inactive).
3	MODEMSTSIT	0	Disables the modem status register interrupt.
		1	Enables the modem status register interrupt
2	LINESTSIT	0	Disables the receiver line status interrupt.
		1	Enables the receiver line status interrupt.
1	THRIT	0	Disables the THR interrupt.
		1	Enables the THR interrupt.
0	RHRIT	0	Disables the RHR interrupt and time out interrupt.
		1	Enables the RHR interrupt and time out interrupt.

Copyright © 2011, Texas Instruments Incorporated

19.5.4 Interrupt Enable Register (IER) - IrDA Mode

The IrDA interrupt enable register (IER) can be programmed to enable/disable any interrupt. There are 8 types of interrupt in these modes, received EOF, LSR interrupt, TX status, status FIFO interrupt, RX overrun, last byte in RX FIFO, THR interrupt, and RHR interrupt. Each interrupt can be enabled/disabled individually. The IrDA interrupt enable register (IER) is shown in Figure 19-37 and described in Table 19-33.

NOTE: The TXSTATUSIT interrupt reflects two possible conditions. The MDR2[0] bit should be read to determine the status in the event of this interrupt.

Figure 19-37. IrDA Interrupt Enable Register (IER)

		1	Enables the received EOF interrupt.
6	LINESTSIT	0	Disables the receiver line status interrupt.
		1	Enables the receiver line status interrupt.
5	TXSTATUSIT	0	Disables the TX status interrupt.
		1	Enables the TX status interrupt.
4	STSFIFOTRIGIT	0	Disables status FIFO trigger level interrupt.
		1	Enables status FIFO trigger level interrupt.
3	RXOVERRUNIT	0	Disables the RX overrun interrupt.
		1	Enables the RX overrun interrupt.
2	LASTRXBYTEIT	0	Disables the last byte of frame in RX FIFO interrupt.
		1	Enables the last byte of frame in RX FIFO interrupt.
1	THRIT	0	Disables the THR interrupt.
		1	Enables the THR interrupt.
0	RHRIT	0	Disables the RHR interrupt.
		1	Enables the RHR interrupt.

Copyright © 2011, Texas Instruments Incorporated

19.5.5 Interrupt Enable Register (IER) - CIR Mode

The CIR interrupt enable register (IER) can be programmed to enable/disable any interrupt. There are 5 types of interrupt in these modes, TX status, RX overrun, RX stop interrupt, THR interrupt, and RHR interrupt. Each interrupt can be enabled/disabled individually. The CIR interrupt enable register (IER) is shown in Figure 19-38 and described in Table 19-34.

NOTE: In CIR mode, the TXSTATUSIT bit has only one meaning corresponding to the case MDR2[0] = 0.

The RXSTOPIT interrupt is generated based on the value set in the BOF Length register (EBLR).

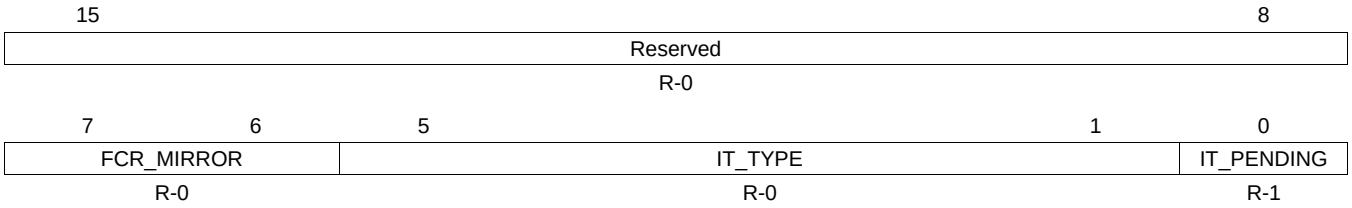
19.5.6 Interrupt Identification Register (IIR) - UART Mode

The UART interrupt identification register (IIR) is a read-only register that provides the source of the interrupt. The UART interrupt identification register (IIR) is shown in Figure 19-39 and described in Table 19-35.

NOTE: An interrupt source can be flagged only if enabled in the IER register.

Figure 19-39. UART Interrupt Identification Register (IIR)



LEGEND: R = Read only; -*n* = value after reset

Table 19-35. UART Interrupt Identification Register (IIR) Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reserved.
7-6	FCR_MIRROR	0-3h	Mirror the contents of FCR[0] on both bits.
5-1	IT_TYPE	0-1Fh	Seven possible interrupts in UART mode; other combinations never occur:
		0	Modem interrupt. Priority = 4.
		1h	THR interrupt. Priority = 3.
		2h	RHR interrupt. Priority = 2.
		3h	Receiver line status error. Priority = 1.
		4h-5h	Reserved
		6h	Rx timeout. Priority = 2.
		7h	Reserved
		8h	Xoff/special character. Priority = 5.
		9h-Fh	Reserved
		10h	$\overline{CTS}$, $\overline{RTS}$, $\overline{DSR}$ change state from active (low) to inactive (high). Priority = 6.
		11h-1Fh	Reserved
0	IT_PENDING		Interrupt pending.
		0	An interrupt is pending.
		1	No interrupt is pending.

19.5.11 Modem Control Register (MCR)

Bits 3-0 control the interface with the modem, data set, or peripheral device that is emulating the modem. The modem control register (MCR) is shown in Figure 19-44 and described in Table 19-40.

Figure 19-44. Modem Control Register (MCR)

15							8
Reserved							
R-0							
7	6	5	4	3	2	1	0
Reserved	TCRTLR	XONEN	LOOPBACKEN	CDSTSCH	RISTSCH	RTS	DTR
R-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 19-40. Modem Control Register (MCR) Field Descriptions

Bit	Field	Value	Description
15-7	Reserved	0	Reserved.
6	TCRTLR		Can be written only when EFR[4] = 1.
		0	No action.
		1	Enables access to the TCR and TLR registers.
5	XONEN		Can be written only when EFR[4] = 1.
		0	Disable XON any function.
		1	Enable XON any function.
4	LOOPBACKEN		Loopback mode enable.
		0	Normal operating mode.
		1	Enable local loopback mode (internal). In this mode, the MCR[3:0] signals are looped back into MSR[7:4]. The transmit output is looped back to the receive input internally.
3	CDSTSCH	0	In loopback mode, forces $\overline{\text{DCD}}$ input high and IRQ outputs to INACTIVE state.
		1	In loopback mode, forces $\overline{\text{DCD}}$ input low and IRQ outputs to INACTIVE state.
2	RISTSCH	0	In loopback mode, forces $\overline{\text{RI}}$ input inactive (high).
		1	In loopback mode, forces $\overline{\text{RI}}$ input active (low).
1	RTS		In loopback mode, controls MSR[4]. If auto-RTS is enabled, the $\overline{\text{RTS}}$ output is controlled by hardware flow control.
		0	Force $\overline{\text{RTS}}$ output to inactive (high).
		1	Force $\overline{\text{RTS}}$ output to active (low).
0	DTR	0	Force $\overline{\text{DTR}}$ output (used in loopback mode) to inactive (high).
		1	Force $\overline{\text{DTR}}$ output (used in loopback mode) to active (low).

19.5.12 Line Status Register (LSR) - UART Mode

When the UART line status register (LSR) is read, LSR[4:2] reflect the error bits (BI, FE, PE) of the character at the top of the RX FIFO (next character to be read). Therefore, reading the LSR and then reading the RHR identifies errors in a character. Reading RHR updates BI, FE, and PE. LSR [7] is set when there is an error anywhere in the RX FIFO and is cleared only when there are no more errors remaining in the RX FIFO. The UART line status register (LSR) is shown in Figure 19-45 and described in Table 19-41.

NOTE: Reading the LSR does not cause an increment of the RX FIFO read pointer. The RX FIFO read pointer is incremented by reading the RHR. Reading LSR clears OE if set.

Figure 19-45. UART Line Status Register (LSR)

15							8

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 19-41. UART Line Status Register (LSR) Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reserved.
7	RXFIFOSTS	0	Normal operation.
		1	At least one parity error, framing error, or break indication in the RX FIFO. Bit 7 is cleared when no errors are present in the RX FIFO.
6	TXSRE	0	Transmitter hold (TX FIFO) and shift registers are not empty.
		1	Transmitter hold (TX FIFO) and shift registers are empty.
5	TXFIFOE	0	Transmit hold register (TX FIFO) is not empty.
		1	Transmit hold register (TX FIFO) is empty. The transmission is not necessarily completed.
4	RXBI	0	No break condition.
		1	A break was detected while the data being read from the RX FIFO was being received (RX input was low for one character + 1 bit time frame).
3	RXFE	0	No framing error in data being read from RX FIFO.
		1	Framing error occurred in data being read from RX FIFO (received data did not have a valid stop bit).
2	RXPE	0	No parity error in data being read from RX FIFO.
		1	Parity error in data being read from RX FIFO.
1	RXOE	0	No overrun error.
		1	Overrun error occurred. Set when the character held in the receive shift register is not transferred to the RX FIFO. This case occurs only when receive FIFO is full.
0	RXFIFOE	0	No data in the receive FIFO.
		1	At least one data character in the RX FIFO.

19.5.13 Line Status Register (LSR) - IrDA Mode

When the IrDA line status register (LSR) is read, LSR[4:2] reflect the error bits (FL, CRC, ABORT) of the frame at the top of the status FIFO (next frame status to be read). The IrDA line status register (LSR) is shown in Figure 19-46 and described in Table 19-42.

Figure 19-46. IrDA Line Status Register (LSR)

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 19-42. IrDA Line Status Register (LSR) Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reserved.
7	THR_EMPTY	0	Transmit holding register (TX FIFO) is not empty.
		1	Transmit hold register (TX FIFO) is empty. The transmission is not necessarily completed.
6	STS_FIFO_FULL	0	Status FIFO is not full.
		1	Status FIFO is full.
5	RX_LAST_BYTE	0	The RX FIFO (RHR) does not contain the last byte of the frame to be read.
		1	The RX FIFO (RHR) contains the last byte of the frame to be read. This bit is set to 1 only when the last byte of a frame is available to be read. It is used to determine the frame boundary. It is cleared on a single read of the LSR register.
4	FRAME_TOO_LONG	0	No frame-too-long error in frame.
		1	Frame-too-long error in the frame at the top of the status FIFO (next character to be read). This bit is set to 1 when a frame exceeding the maximum length (set by RXFLH and RXFLL registers) is received. When this error is detected, current frame reception is terminated. Reception is stopped until the next START flag is detected.
3	ABORT	0	No abort pattern error in frame.
		1	Abort pattern received. SIR and MIR: abort pattern. FIR: Illegal symbol.
2	CRC	0	No CRC error in frame.
		1	CRC error in the frame at the top of the status FIFO (next character to be read).
1	STS_FIFO_E	0	Status FIFO is not empty.
		1	Status FIFO is empty.
0	RX_FIFO_E	0	At least one data character in the RX FIFO.
		1	No data in the receive FIFO.

19.5.15 Modem Status Register (MSR)

The modem status register (MSR) provides information about the current state of the control lines from the modem, data set, or peripheral device to the Local Host. It also indicates when a control input from the modem changes state. The modem status register (MSR) is shown in Figure 19-48 and described in Table 19-44.

Figure 19-48. Modem Status Register (MSR)

15							8

Table 19-44. Modem Status Register (MSR) Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reserved.
7	NCD_STS		This bit is the complement of the $\overline{DCD}$ input. In loopback mode, it is equivalent to MCR[3].
6	NRI_STS		This bit is the complement of the $\overline{RI}$ input. In loopback mode, it is equivalent to MCR[2].
5	NDSR_STS		This bit is the complement of the $\overline{DSR}$ input. In loopback mode, it is equivalent to MCR[0].
4	NCTS_STS		This bit is the complement of the $\overline{CTS}$ input. In loopback mode, it is equivalent to MCR[1].
3	DCD_STS	0	No change.
		1	Indicates that $\overline{DCD}$ input (or MCR[3] in loopback mode) has changed. Cleared on a read.
2	RI_STS	0	No change.
		1	Indicates that $\overline{RI}$ input (or MCR[2] in loopback mode) changed state from low to high. Cleared on a read.
1	DSR_STS	0	No change.
		1	Indicates that $\overline{DSR}$ input (or MCR[0] in loopback mode) changed state. Cleared on a read.
0	CTS_STS	0	No change.
		1	Indicates that $\overline{CTS}$ input (or MCR[1] in loopback mode) changed state. Cleared on a read.

Copyright © 2011, Texas Instruments Incorporated

19.5.16 Transmission Control Register (TCR)

The transmission control register (TCR) stores the receive FIFO threshold levels to start/stop transmission during hardware flow control. The transmission control register (TCR) is shown in Figure 19-49 and described in Table 19-45.

NOTE:

- Trigger levels from 0-60 bytes are available with a granularity of 4.
- Trigger level = 4 × [4-bit register value]
- You must ensure that TCR[3:0] > TCR[7:4], whenever auto-RTS or software flow control is enabled to avoid a misoperation of the device. In FIFO interrupt mode with flow control, you have to also ensure that the trigger level to HALT transmission is greater or equal to receive FIFO trigger level (either TLR[7:4] or FCR[7:6]); otherwise, FIFO operation stalls.
- In FIFO DMA mode with flow control, this concept does not exist because the DMA request is sent each time a byte is received.

Figure 19-49. Transmission Control Register (TCR)

15	8	7	4	3	0

19.5.18 Trigger Level Register (TLR)

This register stores the programmable transmit and receive FIFO trigger levels used for DMA and IRQ generation. The trigger level register (TLR) is shown in Figure 19-51 and described in Table 19-47.

Figure 19-51. Trigger Level Register (TLR)

15 8	7 4	3 0
Reserved	RX_FIFO_TRIG_ DMA	TX_FIFO_TRIG_ DMA
R-0	R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 19-47. Trigger Level Register (TLR) Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reserved.
7-4	RX_FIFO_TRIG_ DMA	0-Fh	Receive FIFO trigger level. See Table 19-48.
3-0	TX_FIFO_TRIG_ DMA	0-Fh	Transmit FIFO trigger level. See Table 19-49.

Table 19-48. RX FIFO Trigger Level Setting Summary

SCR[7]	TLR[7:4]	Description
0	0	Defined by FCR[7:6] (either 8, 16, 56, 60 characters).
0	≠ 0000	Defined by TLR[7:4] (from 4 to 60 characters with a granularity of 4 characters).
1	any value	Defined by the concatenated value of TLR[7:4] and FCR[7:6] (from 1 to 63 characters with a granularity of 1 character). **Note:** the combination of TLR[7:4] = 0000 and FCR[7:6] = 00 (all zeros) is not supported (minimum of 1 character is required). All zeros results in unpredictable behavior.

Table 19-49. TX FIFO Trigger Level Setting Summary

SCR[6]	TLR[3:0]	Description
0	0	Defined by FCR[5:4] (either 8, 16, 32, 56 characters).
0	≠ 0000	Defined by TLR[3:0] (from 4 to 60 characters with a granularity of 4 characters).
1	any value	Defined by the concatenated value of TLR[3:0] and FCR[5:4] (from 1 to 63 characters with a granularity of 1 character). **Note:** the combination of TLR[3:0] = 0000 and FCR[5:4] = 00 (all zeros) is not supported (minimum of 1 character is required). All zeros results in unpredictable behavior.

19.5.19 Mode Definition Register 1 (MDR1)

The mode of operation is programmed by writing to MDR1[2:0]; therefore, the mode definition register 1 (MDR1) must be programmed on startup after configuration of the configuration registers (DLL, DLH, and LCR). The value of MDR1[2:0] must not be changed again during normal operation. The mode definition register 1 (MDR1) is shown in Figure 19-52 and described in Table 19-50.

NOTE: If the module is disabled by setting the MODESELECT field to 7h, interrupt requests can still be generated unless disabled through the interrupt enable register (IER). In this case, UART mode interrupts are visible. Reading the interrupt identification register (IIR) shows the UART mode interrupt flags.

		1	Automatic SIP mode: SIP is generated after each transmission.
5	SCT		Store and control the transmission.
		0	Starts the infrared transmission when a value is written to the THR register.
		1	Starts the infrared transmission with the control of ACREG[2]. **Note:** Before starting any transmission, there must be no reception ongoing.
4	SETTXIR		Used to configure the infrared transceiver.
		0	If MDR2[7] = 0, no action; if MDR2[7] = 1, TXIR pin output is forced low.
		1	TXIR pin output is forced high (not dependant of MDR2[7] value).
3	IRSLEEP		IrDA/CIR sleep mode.
		0	IrDA/CIR sleep mode disabled.
		1	IrDA/CIR sleep mode enabled.
2-0	MODESELECT	0-7h	UART/IrDA/CIR mode selection.
		0	UART 16× mode.
		1	SIR mode.
		2h	UART 16× auto-baud.
		3h	UART 13× mode.
		4h	MIR mode.
		5h	FIR mode.
		6h	CIR mode.
		7h	Disable (default state).

19.5.20 Mode Definition Register 2 (MDR2)

The MDR2[0] bit describes the status of the TX status interrupt in IIR[5]. The IRTXUNDERRUN bit must be read after a TX status interrupt occurs. The MDR2[2:1] bits set the trigger level for the frame status FIFO (8 entries) and must be programmed before the mode is programmed in MDR1[2:0]. The mode definition register 2 (MDR2) is shown in Figure 19-53 and described in Table 19-51.

NOTE: The MDR2[6] bit gives the flexibility to invert the RX pin inside the UART module to ensure that the protocol at the input of the transceiver module has the same polarity at module level. By default, the RX pin is inverted because most of transceiver invert the IR receive pin.

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 19-51. Mode Definition Register 2 (MDR2) Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reserved.
7	SETTXIRALT		Provides alternate functionality for MDR1[4].
		0	Normal mode
		1	Alternate mode for SETTXIR
6	IRRXINVERT		Only for IR mode (IrDA and CIR). Invert RX pin in the module before the voting or sampling system logic of the infrared block. This does not affect the RX path in UART modem modes.
		0	Inversion is performed.
		1	No inversion is performed.
5-4	CIRPULSEMODE	0-3h	CIR pulse modulation definition. Defines high level of the pulse width associated with a digit:
		0	Pulse width of 3 from 12 cycles.
		1h	Pulse width of 4 from 12 cycles.
		2h	Pulse width of 5 from 12 cycles.
		3h	Pulse width of 6 from 12 cycles.
3	UARTPULSE		UART mode only. Used to allow pulse shaping in UART mode.
		0	Normal UART mode.
		1	UART mode with pulse shaping.
2-1	STSFIFOTRIG	0-3h	Only for IrDA mode. Frame status FIFO threshold select:
		0	1 entry
		1h	4 entries
		2h	7 entries
		3h	8 entries
0	IRTXUNDERRUN		IrDA transmission status interrupt. When the TX status interrupt (IIR[5]) occurs, the meaning of the interrupt is:
		0	The last bit of the frame was transmitted successfully without error.
		1	An underrun occurred. The last bit of the frame was transmitted but with an underrun error. The bit is reset to 0 when the RESUME register is read.

Copyright © 2011, Texas Instruments Incorporated

19.5.21 Status FIFO Line Status Register (SFLSR)

Reading the status FIFO line status register (SFLSR) effectively reads frame status information from the status FIFO. This register does not physically exist. Reading this register increments the status FIFO read pointer (SFREGL and SFREGH must be read first). The status FIFO line status register (SFLSR) is shown in Figure 19-54 and described in Table 19-52.

NOTE: Top of RX FIFO = Next frame to be read from RX FIFO.

Figure 19-54. Status FIFO Line Status Register (SFLSR)

4	OE_ERROR	0	No error
		1	Overrun error in RX FIFO when frame at top of RX FIFO was received.
3	FRAME_TOO_LONG_ERROR	0	No error
		1	Frame-length too long error in frame at top of RX FIFO.
2	ABORT_DETECT	0	No error
		1	Abort pattern detected in frame at top of RX FIFO.
1	CRC_ERROR	0	No error
		1	CRC error in frame at top of RX FIFO.
0	Reserved	0	Reserved.

19.5.22 RESUME Register

The RESUME register is used to clear internal flags, which halt transmission/reception when an underrun/overrun error occurs. Reading this register resumes the halted operation. This register does not physically exist and always reads as 00. The RESUME register is shown in Figure 19-55 and described in Table 19-53.

19.5.23 Status FIFO Register Low (SFREGL)

The frame lengths of received frames are written into the status FIFO. This information can be read by reading the status FIFO register low (SFREGL) and the status FIFO register high (SFREGH). These registers do not physically exist. The LSBs are read from SFREGL and the MSBs are read from SFREGH. Reading these registers does not alter the status FIFO read pointer. These registers must be read before the pointer is incremented by reading the SFLSR. The status FIFO register low (SFREGL) is shown in Figure 19-56 and described in Table 19-54.

Figure 19-56. Status FIFO Register Low (SFREGL)

7-0	SFREGL	0-FFh	LSB part of the frame length.

19.5.24 Status FIFO Register High (SFREGH)

The frame lengths of received frames are written into the status FIFO. This information can be read by reading the status FIFO register low (SFREGL) and the status FIFO register high (SFREGH). These registers do not physically exist. The LSBs are read from SFREGL and the MSBs are read from SFREGH. Reading these registers does not alter the status FIFO read pointer. These registers must be read before the pointer is incremented by reading the SFLSR. The status FIFO register high (SFREGH) is shown in Figure 19-57 and described in Table 19-55.

19.5.25 BOF Control Register (BLR)

The BLR[6] bit is used to select whether C0h or FFh start patterns are to be used, when multiple start flags are required in SIR mode. If only one start flag is required, this is always C0h. If *n* start flags are required, either (n – 1) C0h or (n –1) FFh flags are sent, followed by a single C0h flag (immediately preceding the first data byte). The BOF control register (BLR) is shown in Figure 19-58 and described in Table 19-56.

Figure 19-58. BOF Control Register (BLR)

19.5.26 Auxiliary Control Register (ACREG)

The auxiliary control register (ACREG) is shown in Figure 19-59 and described in Table 19-57.

NOTE:

- If transmit FIFO is not empty and MDR1[5] = 1, IrDA starts a new transfer with data of previous frame as soon as abort frame has been sent. Therefore, TX FIFO must be reset before sending an abort frame.
- It is recommended to disable TX FIFO underrun capability by masking corresponding underrun interrupt. When disabling underrun by setting ACREG[4] = 1, unknown data is sent over TX line.

Figure 19-59. Auxiliary Control Register (ACREG)

15							8

PULSETYPE	SDMOD	DISIRRX	DISTXUNDERRUN	SENDSIP	SCTXEN	ABORTEN	EOTEN
R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 19-57. Auxiliary Control Register (ACREG) Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reserved.
7	PULSETYPE		SIR pulse-width select:
		0	3/16 of baud-rate pulse width
		1	1.6 µs
6	SDMOD		Primary output used to configure transceivers. Connected to the SD/MODE input pin of IrDA transceivers.
		0	SD pin is set to high.
		1	SD pin is set to low.
5	DISIRRX		Disable RX input.
		0	Normal operation (RX input automatically disabled during transmit, but enabled outside of transmit operation).
		1	Disables RX input (permanent state; independent of transmit).
4	DISTXUNDERRUN		Disable TX underrun.
		0	Long stop bits cannot be transmitted. TX underrun is enabled.
		1	Long stop bits can be transmitted.
3	SENDSIP		MIR/FIR modes only. Send serial infrared interaction pulse (SIP).
			If this bit is set during an MIR/FIR transmission, the SIP is sent at the end of it. This bit is automatically cleared at the end of the SIP transmission.
		0	No action.
		1	Send SIP pulse.
2	SCTXEN		Store and control TX start. When MDR1[5] = 1 and the LH writes 1 to this bit, the TX state-machine starts frame transmission. This bit is self-clearing.
1	ABORTEN		Frame abort. The LH can intentionally abort transmission of a frame by writing 1 to this bit. Neither the end flag nor the CRC bits are appended to the frame.
0	EOTEN		EOT (end-of-transmission) bit. The LH writes 1 to this bit just before it writes the last byte to the TX FIFO in the set-EOT bit frame-closing method. This bit is automatically cleared when the LH writes to the THR (TX FIFO).

Copyright © 2011, Texas Instruments Incorporated

19.5.27 Supplementary Control Register (SCR)

The supplementary control register (SCR) is shown in Figure 19-60 and described in Table 19-58.

NOTE: Bit 4 enables the wake-up interrupt, but this interrupt is not mapped into the IIR register. Therefore, when an interrupt occurs and there is no interrupt pending in the IIR register, the SSR[1] bit must be checked. To clear the wake-up interrupt, bit SCR[4] must be reset to 0.

19.5.29 BOF Length Register (EBLR)

In IrDA SIR operation, the BOF length register (EBLR) specifies the number of BOF + xBOFs to transmit. The value set into this register must consider the BOF character; therefore, to send only one BOF with no XBOF, this register must be set to 1. To send one BOF with *n* XBOFs, this register must be set to *n* + 1. Furthermore, the value 0 sends 1 BOF plus 255 XBOFs.

In IrDA MIR mode, the BOF length register (EBLR) specifies the number of additional start flags (MIR protocol mandates a minimum of 2 start flags).

In CIR mode, the BOF length register (EBLR) specifies the number of consecutive zeros to be received before generating the RXSTOP interrupt (IIR[2]). All the received zeros are stored in the RX FIFO. When the register is cleared to 0, this feature is deactivated and always in reception state, which is disabled by setting the ACREG[5] bit to 1.

The BOF length register (EBLR) is shown in Figure 19-62 and described in Table 19-60.

NOTE: If the RX_STOP interrupt occurs before a byte boundary, the remaining bits of the last byte are filled with zeros and then passed into the RX FIFO.

Figure 19-62. BOF Length Register (EBLR)

19.5.31 System Configuration Register (SYSC)

The AUTOIDLE bit controls a power-saving technique to reduce the logic power consumption of the module interface; that is, when the feature is enabled, the interface clock is gated off until the module interface is accessed. When the SOFTRESET bit is set high, it causes a full device reset. The system configuration register (SYSC) is shown in Figure 19-64 and described in Table 19-62.

Figure 19-64. System Configuration Register (SYSC)

15 5	4 3	2	1	0

19.5.33 Wake-Up Enable Register (WER)

The wake-up enable register (WER) is used to mask and unmask a UART event that subsequently notifies the system. An event is any activity in the logic that can cause an interrupt and/or an activity that requires the system to wake up. Even if wakeup is disabled for certain events, if these events are also an interrupt to the UART, the UART still registers the interrupt as such. The wake-up enable register (WER) is shown in Figure 19-66 and described in Table 19-64.

19.5.34 Carrier Frequency Prescaler Register (CFPS)

Since the consumer IR (CIR) works at modulation rates of 30–56.8 kHz, the 48 MHz clock must be prescaled before the clock can drive the IR logic. The carrier frequency prescaler register (CFPS) sets the divisor rate to give a range to accommodate the remote control requirements in BAUD multiples of 12×. The value of the CFPS at reset is 105 decimal (69h), which equates to a 38.1 kHz output from starting conditions. The 48 MHz carrier is prescaled by the CFPS that is then divided by the 12× BAUD multiple. The carrier frequency prescaler register (CFPS) is shown in Figure 19-67 and described in Table 19-65.

Figure 19-67. Carrier Frequency Prescaler Register (CFPS)

19.5.35 Divisor Latches Low Register (DLL)

The divisor latches low register (DLL) with the DLH register stores the 14-bit divisor for generation of the baud clock in the baud rate generator. DLH stores the most-significant part of the divisor, DLL stores the least-significant part of the divisor. The DLL register is shown in Figure 19-68 and described in Table 19-66.

NOTE: DLL and DLH can be written to only before sleep mode is enabled (before IER[4] is set).

Figure 19-68. Divisor Latches Low Register (DLL)

19.5.37 Enhanced Feature Register (EFR)

The enhanced feature register (EFR) enables or disables enhanced features. Most enhanced functions apply only to UART modes, but EFR[4] enables write accesses to FCR[5:4], the TX trigger level, which is also used in IrDA modes. The enhanced feature register (EFR) is shown in Figure 19-70 and described in Table 19-68.

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 19-68. Enhanced Feature Register (EFR) Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reserved.
7	AUTOCTSEN		Auto-CTS enable bit (UART mode only).
		0	Normal operation.
		1	Auto-CTS flow control is enabled; transmission is halted when the $\overline{CTS}$ pin is high (inactive).
6	AUTORTSEN		Auto-RTS enable bit (UART mode only).
		0	Normal operation.
		1	Auto-RTS flow control is enabled; $\overline{RTS}$ pin goes high (inactive) when the receiver FIFO HALT trigger level, TCR[3:0], is reached and goes low (active) when the receiver FIFO RESTORE transmission trigger level is reached.
5	SPECIALCHARDETECT		Special character detect (UART mode only).
		0	Normal operation.
		1	Special character detect enable. Received data is compared with XOFF2 data. If a match occurs, the received data is transferred to RX FIFO and the IIR[4] bit is set to 1 to indicate that a special character was detected.
4	ENHANCEDEN		Enhanced functions write enable bit.
		0	Disables writing to IER[7:4], FCR[5:4], and MCR[7:5].
		1	Enables writing to IER[7:4], FCR[5:4], and MCR[7:5].
3-0	SWFLOWCONTROL	0-Fh	Combinations of software flow control can be selected by programming this bit. XON1 and XON2 should be set to different values if the software flow control is enabled. See Table 19-69. In IrDA mode, EFR[1:0] selects the IR address to check. See *IR Address Checking*.

19.5.42 Transmit Frame Length Low Register (TXFLL)

The transmit frame length low register (TXFLL) and the TXFLH register hold the 13-bit transmit frame length (expressed in bytes). TXFLL holds the LSBs and TXFLH holds the MSBs. The frame length value is used if the frame length method of frame closing is used. The transmit frame length low register (TXFLL) is shown in Figure 19-75 and described in Table 19-74.

Figure 19-75. Transmit Frame Length Low Register (TXFLL)

19.5.44 Received Frame Length Low Register (RXFLL)

The received frame length low register (RXFLL) and the RXFLH register hold the 12-bit receive maximum frame length. RXFLL holds the LSBs and RXFLH holds the MSBs. If the intended maximum receive frame length is *n* bytes, program RXFLL and RXFLH to be *n* + 3 in SIR or MIR modes and *n* + 6 in FIR mode (+3 and +6 are the result of frame format with CRC and stop flag; two bytes are associated with the FIR stop flag). The received frame length low register (RXFLL) is shown in Figure 19-77 and described in Table 19-76.

19.5.46 UART Autobauding Status Register (UASR)

The UART autobauding status register (UASR) returns the speed, the number of bits by characters, and the type of parity in UART autobauding mode. In autobauding mode, the input frequency of the UART modem must be fixed to 48 MHz. Any other module clock frequency results in incorrect baud rate recognition. The UART autobauding status register (UASR) is shown in Figure 19-79 and described in Table 19-78.

NOTE:

- This register is used to set up transmission according to characteristics of previous reception, instead of LCR, DLL, and DLH registers when UART is in autobauding mode.
- To reset the autobauding hardware (to start a new “AT” detection) or to set the UART in standard mode (no autobaud), MDR1[2:0] must be set to 7h (reset state), then set to 2h (UART in autobaud mode) or cleared to 0 (UART in standard mode).

Usage limitation:

- Only 7 and 8 bits character (5 and 6 bits not supported).
- 7 bits character with space parity not supported.
- Baud rate between 1200 and 115 200 bp/s (10 possibilities).

20.1 DMTimer

20.1.1 Introduction

20.1.1.1 Overview

The timer module contains a free running upward counter with auto reload capability on overflow. The timer counter can be read and written in real-time (while counting). The timer module includes compare logic to allow an interrupt event on a programmable counter matching value.

A dedicated output signal can be pulsed or toggled on overflow and match event. This output offers a timing stamp trigger signal or PWM (pulse-width modulation) signal sources. A dedicated output signal can be used for general purpose PORGPOCFG (directly driven by bit 14 of the TCLR register). A dedicated input signal is used to trigger automatic timer counter capture and interrupt event, on programmable input signal transition type. A programmable clock divider (prescaler) allows reduction of the timer input clock frequency. All internal timer interrupt sources are merged in one module interrupt line and one wake-up line. Each internal interrupt sources can be independently enabled/disabled.

This module is controllable through the OCP peripheral bus.

As two clock domains are managed inside this module, resynchronization is done by special logic between the OCP clock domain and the Timer clock domain. At reset, synchronization logic allows utilization of all ratios between the OCP clock and the Timer clock. A drawback of this mode is that full-resynchronization path is used with access latency performance impact in terms of OCP clock cycles. In order to improve module access latency, and under restricted conditions on clocks ratios, write-posted mode can be used by setting the POSTED bit of the System Control Register (TSCR). Under this mode, write posted mode is enabled, meaning that OCP write command is granted before write process complete in the timer clock domain. This mode allows software to do concurrent writes on Dual Mode timer registers and to observe write process completion (synchronization) at the software level by reading independent write posted status bits in the Write Posted Status Register (TWPS).

20.1.1.2 Features

The timer consists of the following features:

- Counter timer with compare and capture modes
- Auto-reload mode
- Start-stop mode
- Programmable divider clock source
- 16-32 bit addressing
- “On the fly” read/write registers
- Interrupts generated on overflow, compare and capture
- Interrupt enable
- Wake-up enable
- Write posted mode
- Dedicated input trigger for capture mode and dedicated output trigger/PWM signal
- Dedicated output signal for general purpose use PORGPOCFG
- OCP interface compatible

The Timer resolution and interrupt period are dependent on the selected input clock and clock prescale value. Example resolutions for common clock values are shown in Table 20-1.

Table 20-1. Timer Resolution and Maximum Range

Clock	Prescaler	Resolution	Interrupt Period Range
32.768 KHz	1 (min)	31.25 us	31.25 us to ~36h 35m
	256 (max)	8 ms	8 ms to ~391d 22h 48m

Copyright © 2011, Texas Instruments Incorporated

Table 20-1. Timer Resolution and Maximum Range (continued)

Clock	Prescaler	Resolution	Interrupt Period Range
27 MHz	1 (min)	~37 ns	~37 ns to ~159s
	256 (max)	~9.48 us	~19.7 us to ~11h 18m
38.4 MHz	1 (min)	~26 ns	~26 ns to ~112 s
	256 (max)	~6.7 us	~13.3 us to ~7h 5m

20.1.1.3 Functional Block Diagram

Figure 20-1 shows a block diagram of the timer.

20.1.2 Integration

20.1.2.1 Timer Connectivity Attributes

Table 20-2. Timer[0] Connectivity Attributes

Attributes	Type
Power Domain	Peripheral Domain
Power domain	Wakeup domain
Clock Domain	PD_WKUP_L4_WKUP_GCLK (Interface/OCP) PD_WKUP_TIMER0_GCLK (Func)
Reset Signals	WKUP_DOM_RST_N
Idle/Wakeup Signals	Idle Slave Wakeup
Interrupt Requests	1 to MPU Subsystem (TINT0), 1 to WakeM3
DMA Requests	None
Physical Address	L4 Wakeup slave port

Table 20-3. Timer[2–7] Connectivity Attributes

Attributes	Type
Power Domain	Peripheral Domain
Clock Domain	PD_PER_L4LS_GCLK (OCP) Functional Clocks: PD_PER_TIMER2_GCLK (Timer 2) PD_PER_TIMER3_GCLK (Timer 3) PD_PER_TIMER4_GCLK (Timer 4) PD_PER_TIMER5_GCLK (Timer 5) PD_PER_TIMER6_GCLK (Timer 6) PD_PER_TIMER7_GCLK (Timer 7)
Reset Signals	PER_DOM_RST_N
Idle/Wakeup Signals	Smart Idle
Interrupt Requests	1 per timer module to MPU Subsystem (TINT2 - TINT7) Also to TSC_ADC event capture mux for Timer 4 – Timer7
DMA Requests	Interrupt requests are redirected as DMA requests: 1 per instance (TINTx)
Physical Address	L4 Peripheral slave port

20.1.2.2 Timer Clock and Reset Management

Each DMTimer[2–7] functional clock is selected within the PRCM using the associated CLKSEL_TIMERx_CLK register from 3 possible sources:

- The 24-MHz (typ) system clock (CLK_M_OSC)
- The PER PLL generated 32.768 KHz clock (CLK_32KHZ)
- The TCLKIN external timer input clock.

The DMTimer 0 functional clock is fixed to use the internal 32KHz RC Clock (CLK_RC32K).

20.1.2.3 Timer Clock Signals

Copyright © 2011, Texas Instruments Incorporated

Table 20-4. Timer Clock Signals

Clock Signal	Max Freq	Reference / Source	Comments
Timer[0] Clock Signals			
PICLKOCP Interface clock	100 MHz	CORE_CLKOUTM4 / 2	pd_wkup_l4_wkup_gclk from PRCM
PICLKTIMER Functional clock	25 MHz (1)	CLK_RC32K	pd_wkup_timer0_gclk from PRCM
Timer[2–7] Clock Signals			
PICLKOCP Interface clock	100 MHz	CORE_CLKOUTM4 / 2	pd_per_l4ls_gclk from PRCM
PICLKTIMER Functional clock	25 MHz (1)	CLK_M_OSC CLK_32KHZ (PER_CLKOUTM2 / 5859.375) TCLKIN	pd_per_timer2_gclk pd_per_timer3_gclk pd_per_timer4_gclk pd_per_timer5_gclk pd_per_timer6_gclk pd_per_timer7_gclk from PRCM

(1) PICLKTIMER must be less than PICLKOCP/4.

20.1.2.4 Timer Pin List

The timer PIEVENTCAPT input and PORTIMERPWM output signals are muxed onto a single TIMER I/O pad. The pad direction (and hence the pin function) are controlled from within the DMTimer module using the PORGPOCFG signal as an output enable.

Table 20-5. Timer Pin List

Pin	Type	Description
TCLKIN	I	External timer clock source
TIMER4	I/O	Timer 4 trigger input or PWM output
TIMER5	I/O	Timer 5 trigger input or PWM output
TIMER6	I/O	Timer 6 trigger input or PWM output
TIMER7	I/O	Timer 7 trigger input or PWM output

20.1.3 Functional Description

20.1.3.1 Functional Description

The general-purpose timer is an upward counter. It supports 3 functional modes:

- Timer mode
- Capture mode
- Compare mode

By default, after core reset, the capture and compare modes are disabled.

20.1.3.1.1 Timer Mode Functionality

The timer is an upward counter that can be started and stopped at any time through the Timer Control Register (TCLR ST bit). The Timer Counter Register (TCRR) can be loaded when stopped or on the fly (while counting). TCRR can be loaded directly by a TCRR Write access with the new timer value. TCRR can also be loaded with the value held in the Timer Load Register TLDR by a trigger register (TTGR) Write access. The TCRR loading is done regardless the TTGR written value. The timer counter register TCRR value can be read when stopped or captured on the fly by a TCRR Read access. The timer is stopped and the counter value is cleared to “0” when the module’s reset is asserted. The timer is maintained in stop after reset is released. When the timer is stopped TCRR is frozen and it can be restarted from the frozen value unless TCRR has been reloaded with a new value.

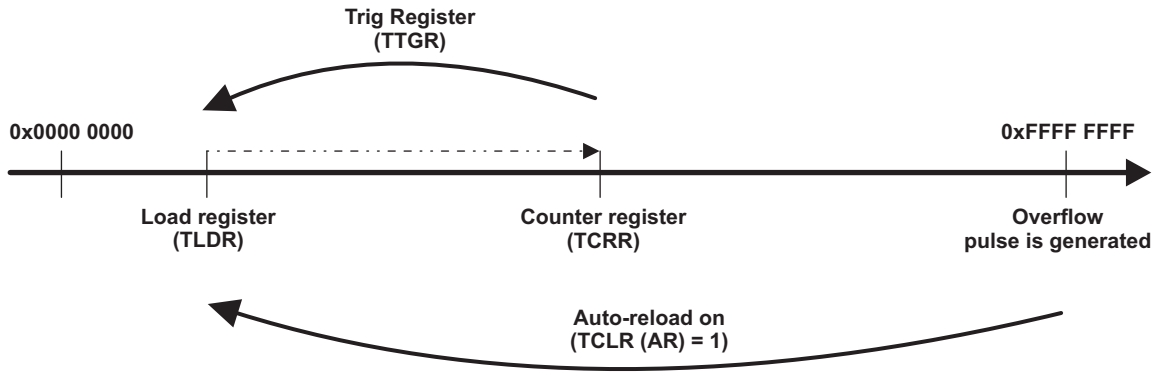
In the one shot mode (TCLR AR bit = 0), the counter is stopped after counting overflow (counter value remains at zero).

When the auto-reload mode is enabled (TCLR AR bit = 1), the TCRR is reloaded with the Timer Load Register (TLDR) value after a counting overflow.

It is not recommended to put the overflow value (FFFF FFFFh) in TLDR because it can lead to undesired results.

An interrupt can be issued on overflow if the overflow interrupt enable bit is set in the timer Interrupt Enable Register (IRQENABLE_SET OVF_IT_FLAG bit = 1). A dedicated output pin (PORTIMERPWM) is programmed through TCLR (TRG and PT bits) to generate one positive pulse (prescaler duration) or to invert the current value (toggle mode) when an overflow occurs.

Figure 20-2. TCRR Timing Value



20.1.3.1.2 Capture Mode Functionality

The timer value in TCRR can be captured and saved in TCAR1 or TCAR2 function of the mode selected in TCLR through the field CAPT_MODE when a transition is detected on the module input pin (PIEVENTCAPT). The edge detection circuitry monitors transitions on the input pin (PIEVENTCAPT).

Copyright © 2011, Texas Instruments Incorporated

Rising transition, falling transition or both can be selected in TCLR (TCM bit) to trig the timer counter capture. The module sets the IRQSTATUS (TCAR_IT_FLAG bit) when an active transition is detected and at the same time the counter value TCRR is stored in one of the timer capture registers TCAR1 or TCAR2 as follows:

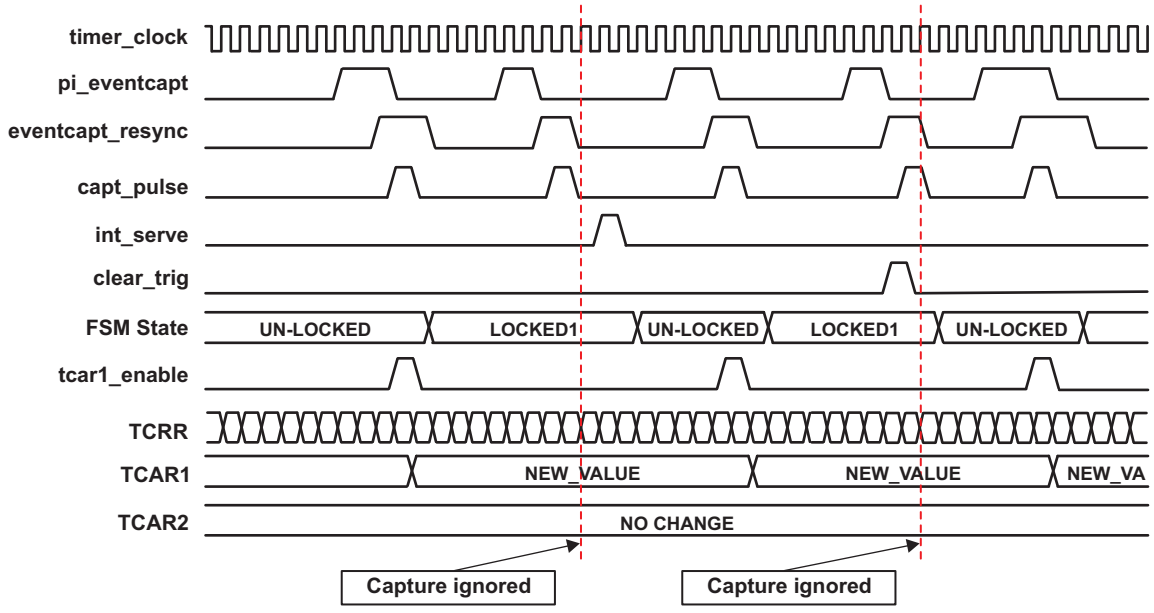
- If TCLR's CAPT_MODE field is 0 then, on the first enabled capture event, the value of the counter register is saved in TCAR1 register and all the next events are ignored (no update on TCAR1 and no interrupt triggering) until the detection logic is reset or the interrupt status register is cleared on TCAR's position writing a 1 in it.
- If TCLR's CAPT_MODE field is 1 then, on the first enabled captured event, the counter value is saved in TCAR1 register and, on the second enabled capture event, the value of the counter register is saved in TCAR2 register. All the other events are ignored (no update on TCAR1/2 and no interrupt triggering) until the detection logic is reset or the interrupt status register is cleared on TCAR's position writing a 1 in it. This mechanism is useful for period calculation of a clock if that clock is connected to the PIEVENTCAPT input pin.

The edge detection logic is reset (a new capture is enabled) when the active capture interrupt is served - TCAR_IT_FLAG bit of IRQSTATUS (previously 1) is cleared. The timer functional clock (input to prescaler) is used to sample the input pin (PIEVENTCAPT). Input negative or positive pulse can be detected when pulse time is above functional clock period. An interrupt can be issued on transition detection if the capture interrupt enable bit is set in the Timer Interrupt Enable Register IRQENABLE_SET (TCAR_IT_FLAG bit).

In Figure 20-3, the TCM value is 01 and CAPT_MODE is 0 - only rising edge of the PIEVENTCAPT will trigger a capture in TCAR and only TCAR1 will update.

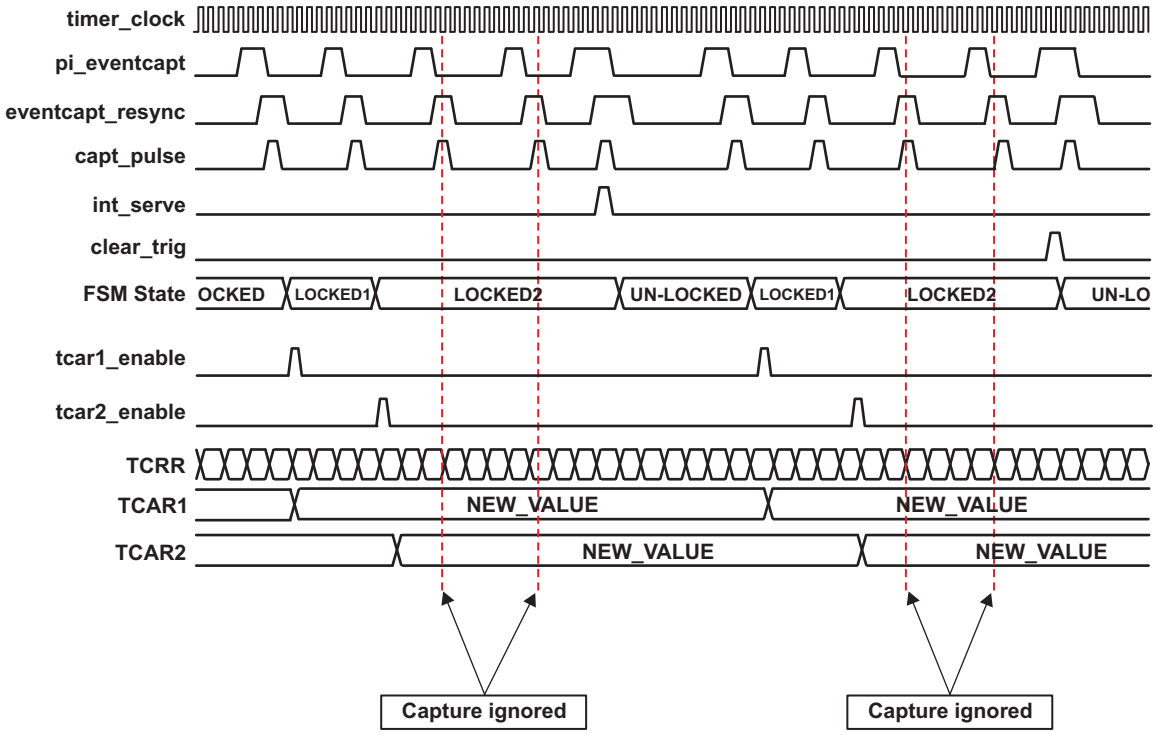
In Figure 20-4, the TCM value is 01 and CAPT_MODE is 1 - only rising edge of the PIEVENTCAPT will trigger a capture in TCAR1 on first enabled event and TCAR2 will update on the second enabled event.

Figure 20-3. Capture Wave Example for CAPT_MODE = 0



Copyright © 2011, Texas Instruments Incorporated

Figure 20-4. Capture Wave Example for CAPT_MODE = 1



20.1.3.1.3 Compare Mode Functionality

When Compare Enable TCLR (CE bit) is set to 1, the timer value (TCRR) is permanently compared to the value held in timer match register (TMAR). TMAR value can be loaded at any time (timer counting or stop). When the TCRR and the TMAR values match, an interrupt can be issued if the IRQENABLE_SET (MAT_EN_FLAG bit) is set. The right programming way is to write a compare value in TMAR register before setting TCLR (CE bit) to avoid any unwanted interrupt due to a reset value matching effect.

The dedicated output pin (PORTIMERPWM) can be programmed through TCLR (TRG and PT bits) to generate one positive pulse (TIMER clock duration) or to invert the current value (toggle mode) when an overflow and a match occur.

20.1.3.1.4 Prescaler Functionality

A prescaler counter can be used to divide the timer counter input clock frequency. The prescaler is enabled when TCLR bit 5 is set (PRE). The 2n division ratio value (PTV) can be configured in the TCLR register. The prescaler counter is reset when the timer counter is stopped or reloaded on the fly.

Table 20-6. Prescaler Functionality

Contexts	Prescaler Counter	Timer Counter
Overflow (when Auto-reload on)	Reset	TLDR
TCRR Write	Reset	TCRR
TTGR Write	Reset	TLDR
Stop	Reset	Frozen

Copyright © 2011, Texas Instruments Incorporated

20.1.3.1.5 Pulse-Width Modulation

The timer can be configured to provide a programmable pulse-width modulation (PORTIMERPWM) output. The PORTIMERPWM output pin can be configured to toggle on specified event. TCLR (TRG bits) determines on which register value the PORTIMERPWM pin toggles. Either overflow or match can be used to toggle the PORTIMERPWM pin, when a compare condition occurs.

In case of overflow and match mode, the match event will be ignored from the moment the mode was set-up until the first overflow event occurs (see Figure 20-4).

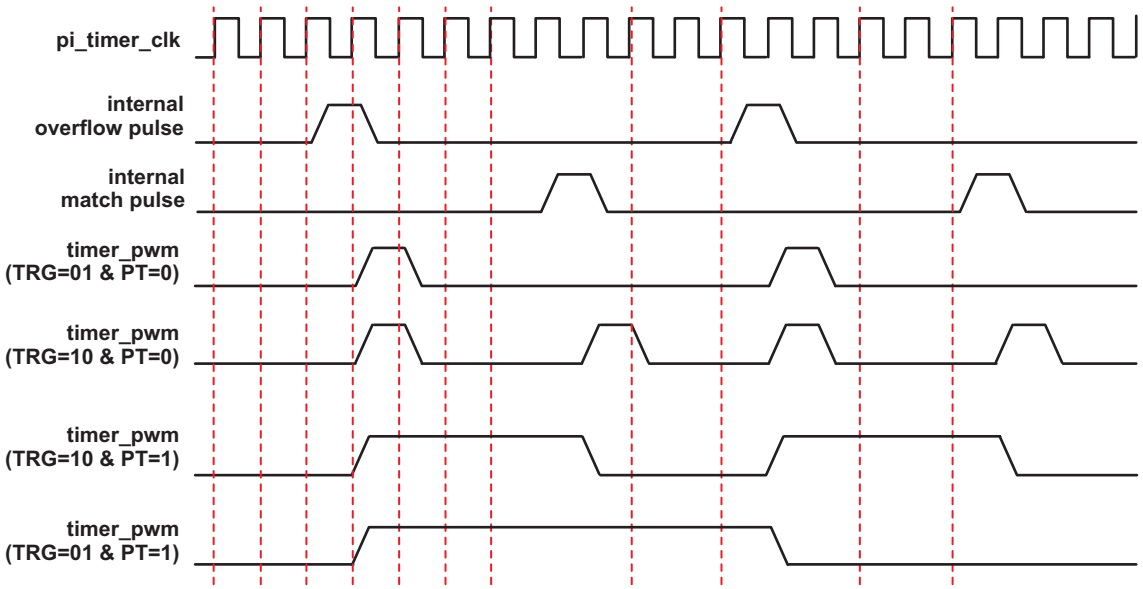
The TCLR (SCPWM bit) can be programmed to set or clear the PORTIMERPWM output signal while the counter is stopped or the triggering is off only. This allows fixing a deterministic state of the output pin when modulation is stopped. The modulation is synchronously stopped when TRG bit is cleared and overflow occurred.

In the following timing diagram, the internal overflow pulse is set each time (FFFF FFFFh – TLDR + 1) value is reached, and the internal match pulse is set when the counter reaches TMAR register value. According to TCLR (TRG and PT bits) programming value, the timer provides pulse or PWM on the output pin (PORTIMERPWM).

The TLDR and TMAR registers must keep values smaller than the overflow value (FFFF FFFFh) with at least 2 units. In case the PWM trigger events are both overflow and match, the difference between the values kept in TMAR register and the value in TLDR must be at least 2 units. When match event is used the compare mode TCLR (CE) must be set.

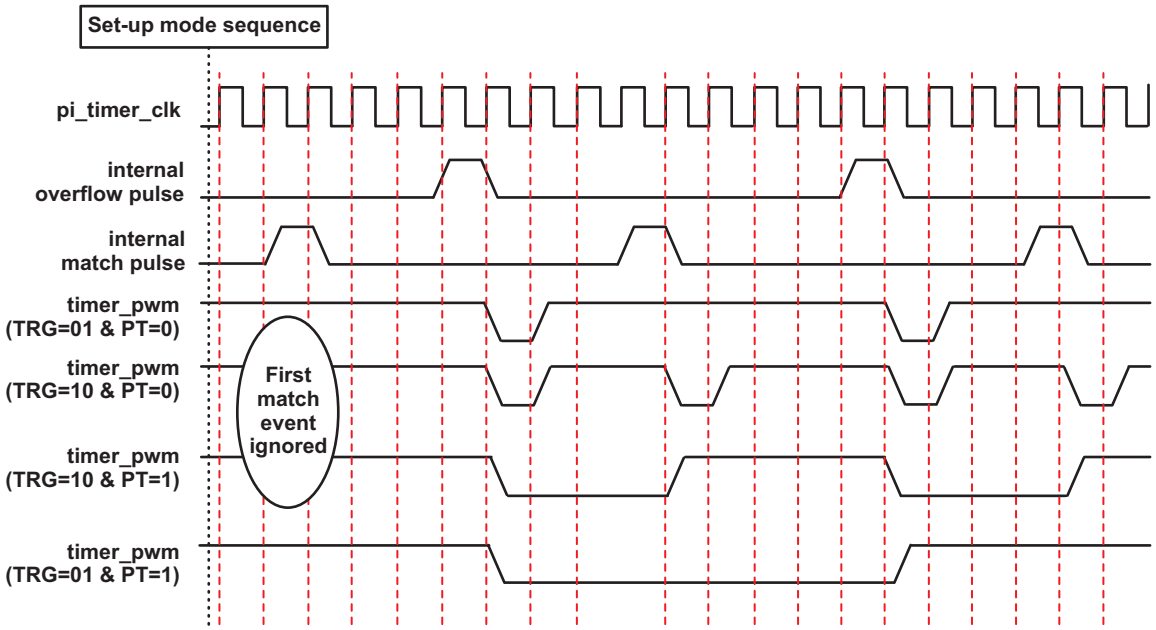
In Figure 20-5, TCLR (SCPWM bit) is cleared to 0. In Figure 20-6, TCLR (SCPWM bit) is set to 1.

Figure 20-5. Timing Diagram of Pulse-Width Modulation with SCPWM = 0



Copyright © 2011, Texas Instruments Incorporated

Figure 20-6. Timing Diagram of Pulse-Width Modulation with SCPWM = 1



Copyright © 2011, Texas Instruments Incorporated

20.1.3.1.6 Timer Counting Rate

The timer counter is composed of a prescaler stage and a timer counter. Prescaler stage is clocked with the timer clock and acts as a clock divider for the timer counter stage. The ratio can be managed by accessing the ratio definition field of the control register (PTV and PRE of TCLR). See Table 20-7.

The timer rate is defined by:

- The value of the prescaler fields (PRE and PTV of TCLR register)
- The value loaded into the Timer Load Register (TLDR).

Table 20-7. Prescaler Clock Ratios Value

PRE	PTV	Divisor (PS)
0	X	1
1	0	2
1	1	4
1	2	8
1	3	16
1	4	32
1	5	64
1	6	128
1	7	256

The timer rate equation is as follows:

(FFFF FFFFh – TLDR + 1) × timer Clock period × Clock Divider (PS)

With timer Clock period = 1/ timer Clock frequency and PS = 2(PTV + 1).

As an example, if we consider a timer clock input of 32 kHz, with a PRE field equal to 0, the timer output period is:

Table 20-8. Value and Corresponding Interrupt Period

TLDR	Interrupt period
0000 0000h	37 h
FFFF 0000h	2 s
FFFF FFF0h	500 us
FFFF FFFEh	62.5 us

20.1.3.1.7 Dual Mode Timer Under Emulation

During emulation mode (when PINSUSPENDN signal is active), the timer can/cannot continue running according to the value of the EmuFree bit of the timer OCP configuration register (TIOCP_CFG).

If EmuFree is 1, timer execution is not stopped and, regardless of the value of PINSUSPENDN signal, and the interrupt assertion is still generated when overflow is reached.

If EmuFree is 0, counters (prescaler/timer) are frozen and an increment start occurs again as soon as PINSUSPENDN becomes inactive. The asynchronous input pin is internally synchronized on 2 TIMER clock rising edges.

Copyright © 2011, Texas Instruments Incorporated

20.1.3.2 Accessing Registers

All registers are 32-bit wide, accessible via OCP interface with 16-bit or 32-bit OCP access (Read/Write). The 32-bit registers write update in 16 bits access must be LSB16 first and the second write access must be MSB16. For the write operation, the module allows skipping the MSB access if the user does not need to update the 16 MSB bits of the register, but only for the OCP registers (TIDR, TIOCP_CFG, IRQ_EOI, IRQSTATUS_RAW, IRQSTATUS, IRQENABLE_SET, IRQENABLE_CLR, IRQWAKEEN and TSICR). The write operation on any functional register (TCLR, TCRR, TLDR, TTGR and TMAR) must be complete (the MSB must be written even if the MSB data is not used).

20.1.3.2.1 Programming the Timer Registers

The TLDR, TCRR, TCLR, TIOCP_CFG, IRQ_EOI, IRQSTATUS, IRQENABLE_SET, IRQENABLE_CLR, IRQWAKEEN, TTGR, TSICR and TMAR registers write is done synchronously with OCP clock, by the host, using the OCP bus protocol.

20.1.3.2.2 Reading the Timer Registers

The counter register (TCRR) is a 32-bit “atomic datum” and 16-bit capture is done on the 16-bit LSB first to allow atomic LSB16 + MSB16 capture. Atomic capture is also performed for the TCAR1 and TCAR2 registers as they may change due to internal processes.

20.1.3.2.3 OCP Error Generation

The timer module responds with error indication in the following cases:

Error on write transactions

- Assert the PORSRESP = ERR signal in the same cycle as PORSCMDACCEPTED.
- Use the ERR code for PORSRESP during the response phase.

Error on read transactions

- Assert the PORSRESP = ERR signal in the same cycle as PORSCMDACCEPTED.
- Use the ERR code for PORSRESP during the response phase. PORSDATA in this case is not valid.

Table 20-9. OCP Error Reporting

Error Type	Response: SRESP = ERR
Unsupported PIOCPMCMD command	Yes
Address error: Read or write to a non-existing internal address	No
Read to write-only registers and write to read-only registers	No
Unaligned address (PIOCPMADDR ≠ 00) on read/write transaction	Yes
Unsupported PIOCPMBYTEEN on read/write transaction	Yes

NOTE: Byte enable “0000” is a supported byte enable.

20.1.3.3 Posted Mode Selection

A choice between the two synchronization modes will be made taking into account the frequency ratio and the stall periods that can be supported by the system, without impacting the global performance.

The posted mode selection applies only to functional registers that require synchronization on/from timer clock domain. For write operation the registers affected by this posted/non-posted selection are: TCLR, TLDR, TCRR, TTGR and TMAR. For read operation the register affected by this posted/non-posted selection are: TCRR, TCAR1 and TCAR2.

Copyright © 2011, Texas Instruments Incorporated

The OCP clock domain synchronous registers TIDR, TIOCP_CFG, TISTAT, IRQ_EOI,IRQSTATUS,IRQSTATUS_RAW, IRQENABLE_SET, IRQENABLE_CLR, IRQWAKEEN, TWPS and TSICR are not affected by the posted/non-posted mode selection; the write/read operation is effective and acknowledged (command accepted) after one OCP clock cycle from the command assertion.

The configuration posted/non-posted is made by setting the PIFREQRATIO when the module is integrated. The PIFREQRATIO signal should be tied to '1' when the freq (timer) < freq (OCP)/4 frequency, and tied to 0 when it is the opposite frequency ratio. The PIFREQRATIO represent the reset value of the TSICR (POSTED bit). The configuration can be changed (overwritten) by software, writing the TSICR (POSTED bit) register.

The following cases are possible:

- Posted Mode can be used when the functional frequency range is: freq (timer) < freq (OCP)/4.
- Non-Posted Mode can be used regardless of the frequency range. Recommended frequency is: freq (timer) >= freq (OCP)/4.

NOTE: The Non-Posted Mode can be also used when freq (timer) < freq (OCP)/4, but it is recommended to use the Posted Mode. Using Non-Posted Mode will delay the command accept and the transaction latency will be as described in the below chapters. Posted mode offers an OCP interface latency improvement and can be used only if the frequencies respect the freq (timer) < freq (OCP)/4 formula.

20.1.3.4 Write Registers Access

20.1.3.4.1 Write Posted

This mode can be used only if the functional frequency range is freq (timer) < freq (OCP)/4.

This mode is used if TSICR (POSTED bit) is set to 1 in the timer control register.

This mode uses a posted-write scheme to update any internal register. The write transaction is immediately acknowledged on the OCP interface, although the effective write operation will occur later, due to a resynchronisation in the timer clock domain. This has the advantage of not stalling either the interconnect system, or the CPU that requested the write transaction. For each register, a status bit is provided, that is set if there is a pending write access to this register.

In this mode, it is mandatory that the CPU checks the status bit prior to any write access. In case a write is attempted to a register with a previous access pending, the previous access is discarded without notice (this can lead to unexpected results also).

There is one status bit per register, accessible in the Timer Write Posted Status Register. When the timer module operates in this mode, there is an automatic sampling of the current timer counter value, in an OCP-synchronized capture register. Consequently, any read access to the timer counter register does not add any re-synchronization latency; the current value is always available.

A register read following a write posted register (on the same register) is not insured to read the previous write value if the write posted process is not completed. Software synchronization should be used to avoid non-coherent read.

The drawback of this automatic update mechanism is that it assumes a given relationship between the OCP interface frequency and the timer functional frequency.

This posted period is defined as the interval between the posted write access request and the reset of the posted bit in TWPS register, and can be quantified:

T (reset posted max.) = 3 OCP clock + 2.5 TIMER clock

The time when the write accomplishes is:

T (write accomplish) = 1 OCP clock + 2.5 TIMER clock

Copyright © 2011, Texas Instruments Incorporated

20.1.3.4.2 Write Non-Posted

This mode is functional regardless of the ratio between the OCP interface frequency and the functional clock frequency. Recommended functional frequency range is freq (timer) >= freq (OCP)/4.

This mode is used if TSICR (POSTED bit) is cleared to 0 in the timer control register.

This mode uses a non posted-write scheme to update any internal register. That means the write transaction will not be acknowledged on the OCP interface, until the effective write operation occurs, after the resynchronisation in the timer clock domain. The drawback is that both the interconnect system and the CPU are stalled during this period.

- The latency of the interrupt serving is increased, as the interconnect system and CPU are stalled.
- An interconnect logic, including time-out logic to detect erroneous transactions, can generate an unwanted system abort event.

The stall period is defined as the interval between the non-posted write access request and the rise of the command accept signal and can be quantified:

T (stall max.) = 3 OCP clock + 2.5 TIMER clock

The time when the write accomplishes is:

T (write accomplish) = 1 OCP clock + 2.5 TIMER clock

A register read following a write to the same register is always coherent.

20.1.3.5 Read Registers Access

20.1.3.5.1 Read Posted

This mode can be used only if the functional frequency range is freq (timer) < freq (OCP)/4.

This mode is used if TSICR (POSTED bit) is set to 1 in the timer control register.

This mode uses a posted-read scheme, for reading any internal register. The read transaction is immediately acknowledged on the OCP interface, and the value to be read has been previously resynchronised. This has the advantage of not stalling either the interconnect system, or the CPU that requested the read transaction.

20.1.3.5.2 Read Non-Posted

This mode is functional whatever the ratio between the OCP interface frequency and the functional clock frequency. Recommended functional frequency range is freq (timer) >= freq (OCP)/4.

This mode is used if TSICR (POSTED bit) is cleared to 0 in the timer control register.

This mode uses a non posted-read scheme, for reading any internal register. The read transaction will not be acknowledged on the OCP interface, until the effective read operation occurs, after the resynchronisation in the timer clock domain. The drawback is that both the interconnect system and the CPU are stalled during this period.

- The latency of the interrupt serving is increased, as the interconnect system and the CPU are stalled.
- An interconnect system including time-out logic to detect erroneous transactions can generate an unwanted system abort event.

This mode only applies only to three registers: TCRR, TCAR1 and TCAR2, which need resynchronisation from functional to OCP clock domains.

The stall period is defined as the interval between the non-posted read access request and the rise of the command accept signal and can be quantified:

T (stall max.) = 3 OCP clock + 2.5 TIMER clock

The time when the value is sampled is:

T (read sample) = 1 OCP clock + 2.5 TIMER clock

20.1.5 Timer Registers

The timer registers are listed in Table 20-10. All registers are:

- 32-bit register accessible in 16-bit mode
- Little-endian addressing

Table 20-10. Timer Registers

Address Offset	Acronym	Register Name
00h	TIDR	Identification Register
10h	TIOCP_CFG	Timer OCP Configuration Register
20h	IRQ_EOI	Timer IRQ End-Of-Interrupt Register
24h	IRQSTATUS_RAW	Timer IRQSTATUS Raw Register
28h	IRQSTATUS	Timer IRQSTATUS Register
2Ch	IRQSTATUS_SET	Timer IRQENABLE Set Register
30h	IRQSTATUS_CLR	Timer IRQENABLE Clear Register
34h	IRQWAKEEN	Timer IRQ Wakeup Enable Register

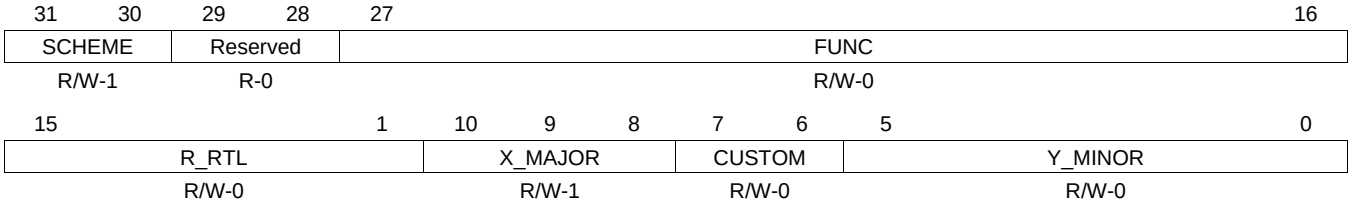
20.1.5.1 Identification Register (TIDR)

This read only register contains the revision number of the module. A write to this register has no effect. This register is used by software to track features, bugs, and compatibility.

Figure 20-7. Identification Register (TIDR) Register



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 20-11. Identification Register (TIDR) Field Descriptions

Bit	Field	Value	Description
31-30	SCHEME	1	Used to distinguish between old scheme and current.
29-28	Reserved	0	Reads return 0
27-16	FUNC	0	Function indicates a software compatible module family.
15-11	R_RTL	0	RTL Version (R).
10-8	X_MAJOR	1	Major Revision (X).
7-6	CUSTOM	0	Indicates a special version for a particular device.
5-0	Y_MINOR	0	Minor Revision (Y).

Copyright © 2011, Texas Instruments Incorporated

20.1.5.2 Timer OCP Configuration Register (TIOCP_CFG)

This register allows controlling various parameters of the OCP interface.

Figure 20-8. Timer OCP Configuration Register (TIOCP_CFG)

31	4	3	2	1	0
Reserved		IDLEMODE		EMUFREE	SOFTRESET
R-0		R/W-0		R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 20-12. Timer OCP Configuration Register (TIOCP_CFG) Field Descriptions

Bit	Field	Value	Description
31-4	Reserved	0	Reserved
3-2	IDLEMODE		Power management, req/ack control
		0	Force-idle mode: local target's idle state follows (acknowledges) the system's idle requests unconditionally, i.e. regardless of the IP module's internal requirements. Backup mode, for debug only.
		1h	No-idle mode: local target never enters idle state. Backup mode, for debug only.
		2h	Smart-idle mode: local target's idle state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements. IP module shall not generate (IRQ- or DMA-request-related) wakeup events.
		3h	Smart-idle wakeup-capable mode: local target's idle state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements. IP module may generate (IRQ- or DMA-request-related) wakeup events when in idle state. Mode is only relevant if the appropriate IP module "swakeup" output(s) is (are) implemented.
1	EMUFREE		Emulation mode
		0	The timer is frozen in emulation mode (PINSUSPENDN signal active).
		1	The timer runs free, regardless of PINSUSPENDN value.
0	SOFTRESET		Software reset

20.1.5.10 Timer Counter Register (TCRR)

The TCRR register is a 32-bit register, 16-bit addressable. The MCU can perform a 32-bit access or two 16-bit accesses to access the register. Note that since the OCP clock is completely asynchronous with the timer clock, some synchronization is done in order to make sure that the TCRR value is not read while it is being incremented.

In 16-bit mode the following sequence must be followed to read the TCRR register properly:

- Perform an OCP Read Transaction to Read the lower 16-bit of the TCRR register (offset = 28h). When the TCRR is read and synchronized, the lower 16-bit LSBs are driven onto the output OCP data bus and the upper 16-bit MSBs of the TCRR register are stored in a temporary register.
- Perform an OCP Read Transaction to read the upper 16-bit of the TCRR register (offset = 2Ah). During this Read, the value of the upper 16-bit MSBs that has been temporary register is forwarded onto the output OCP data bus.

So, to read the value of TCRR correctly, the first OCP read access has to be to the lower 16-bit (offset = 28h), followed by OCP read access to the upper 16-bit (offset = 2Ah).

As the TCRR is updated using more sources (shadow_in_tcrr, incremented value of tcrr, TLDR and “0”), a priority order will be defined:

- The first priority is the OCP update
- The second is the reload way (triggered through TTGR reg. or following an auto-reload overflow)
- The third is the one-shot overflow reset to 0
- The last is the incremented value

20.1.5.15 Timer Capture Register (TCAR1)

When the appropriate (rising, falling or both) transition is detected in the edge detection logic the current counter value is stored to the TCAR1 register. Note that since the OCP clock is completely asynchronous with the timer clock, some synchronization is done in order to make sure that the TCAR1 value is not read while it is being updated due to some capture event.

In 16-bit mode the following sequence must be followed to read the TCAR1 register properly:

- Perform an OCP Read Transaction to Read the lower 16-bits of the TCAR1 register.
- Perform an OCP Read Transaction to read the upper 16-bits of the TCAR1 register.

Figure 20-21. Timer Capture Register (TCAR1)

20.1.5.16 Timer Synchronous Interface Control Register (TSICR)

Access to this register is not stalled even if the timer is in non-posted mode configuration. To abort any wrong behavior, software can permanently reset the functional part of the module. Also in case of a wrong hardware PIFREQRATIO tied the POSTED field can be reprogrammed on the fly, so deadlock situation cannot happen.

NOTE: Reset value of POSTED depends on hardware integration module at design time. Software must read POSTED field to get the hardware module configuration.

Figure 20-22. Timer Synchronous Interface Control Register (TSICR)

Bit	Field	Value	Description
31-3	Reserved	0	Reserved
2	POSTED		PIFREQRATIO
		0	Posted mode inactive: will delay the command accept output signal.
		1	Posted mode active (clocks ratio needs to fit freq (timer) < freq (OCP)/4 frequency requirement)
1	SFT		This bit resets all the function parts of the module. During reads it always returns 0.
		0	Software reset is enabled
		1	Software reset is disabled
0	Reserved	0	Reserved

20.1.5.17 Timer Capture Register (TCAR2)

When the appropriate (rising, falling or both) transition is detected in the edge detection logic and the capture on second event is activated from the control register (TCLR), the current counter value is stored to the TCAR2 register. Note that since the OCP clock is completely asynchronous with the timer clock, some synchronization is done in order to make sure that the TCAR2 value is not read while it is being updated due to some capture event.

In 16-bit mode the following sequence must be followed to read the TCAR2 register properly:

- Perform an OCP Read Transaction to Read the lower 16-bits of the TCAR2 register.
- Perform an OCP Read Transaction to read the upper 16-bits of the TCAR2 register.

20.2 DMTimer 1ms

20.2.1 Introduction

This peripheral is a 32-bit timer offering:

- Counter timer with compare and capture modes
- Auto-reload mode
- Start-stop mode
- Generate 1 ms tick with 32768-Hz functional clock
- Programmable divider clock source
- 16–32 bit addressing
- On-the-fly read/write registers
- Interrupts generated on overflow, compare and capture
- Interrupt enable
- Wake-up enable
- Write posted mode
- Dedicated input trigger for capture mode and dedicated output trigger/PWM signal
- Dedicated output signal for general purpose use PORGPOCFG
- OCP interface compatible

The timer module contains a free running upward counter with auto reload capability on overflow. The timer counter can be read and written on the fly (while counting). The timer module includes compare logic to allow interrupt event on programmable counter matching value.

A dedicated output signal can be pulsed or toggled on overflow and match event. This output offers timing stamp trigger signal or PWM (pulse width modulation) signal sources. A dedicated output signal can be used for general purpose PORGPOCFG (directly driven by the bit 14 of the TCLR register). A dedicated input signal is used to trigger automatic timer counter capture and interrupt event, on programmable input signal transition type. A programmable clock divider (prescaler) allows reduction of the timer input clock frequency. All internal timer interrupt sources are merged in one module interrupt line and one wake-up line. Each internal interrupt sources can be independently enabled/disabled with a dedicated bit of TIER register for the interrupt features and a dedicated bit of TWER for the wake-up.

This module is controllable through the OCP peripheral bus.

As 2 clocks domains are managed inside this module, resynchronization is done by special logic between OCP clock domain and Timer clock domain. At reset, synchronization logic allows utilization of all ratios between OCP clock and Timer clock. Drawback of this mode is that full-resynchronization path is used with access latency performance impact in terms of OCP clock cycles. In order to improve module access latency, and under restricted conditions on clocks ratios (cf. 7.1 Write posted), write-posted mode can be used by setting POSTED bit of System Control register (TSICR). Under this mode, write posted mode is enabled, meaning that OCP write command is granted before write process complete in the timer clock domain. This mode allows software (SW) to do concurrent writes on Dual Mode timer registers and to observe write process completion (synchronization) at SW level by reading independent write posted status bits in the Write Posted Status Register (TWPS).

20.2.2 Integration

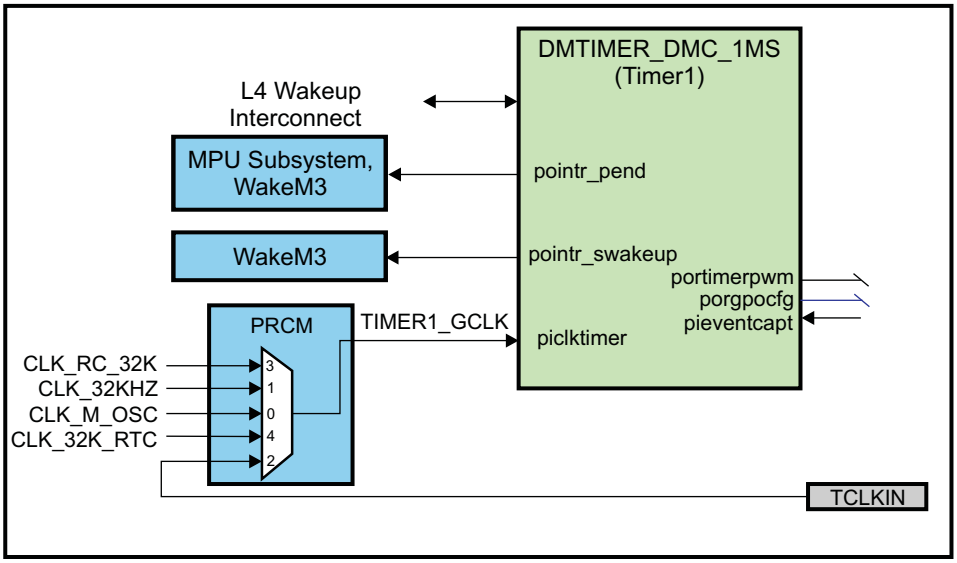

Figure 20-25. DMTimer 1 ms Integration

20.2.2.1 Timer Connectivity Attributes

Table 20-28. Timer1 Connectivity Attributes

Attributes	Type
Power Domain	Wakeup Domain
Clock Domain	PD_WKUP_L4_WKUP_GCLK (OCP) PD_WKUP_TIMER1_GCLK (Func)
Reset Signals	WKUP_DOM_RST_N
Idle/Wakeup Signals	Smart Idle / Slave Wakeup
Interrupt Requests	1 to MPU Subsystem (TINT1_1MS) and WakeM3
DMA Requests	None
Physical Address	L4 Wakeup slave port

20.2.2.2 Timer Clock and Reset Manangement

The DMTimer1 1ms timer functional clock can be selected from one of five sources using the CLKSEL_TIMER1MS_CLK register in the PRCM:

- The 24 MHz (typ) system clock (CLK_M_OSC)
- The PER PLL generated 32.768 KHz clock (CLK_32KHZ)
- The TCLKIN external timer input clock
- The on-chip ~32.768 KHz oscillator (CLK_RC32K)
- The external 32.768 KHz oscillator/clock (CLK_32K_RTC)

20.2.2.3 Timer Clock Signals

Table 20-29. Timer Clock Signals

Clock Signal	Max Freq	Reference / Source	Comments
Timer1 (1ms) Clock Signals			
PICLKOCP Interface clock	100 MHz	CORE_CLKOUTM4 / 2	pd_wkup_l4_wkup_gclk from PRCM
PICLKTIMER Functional clock	25 MHz[(1)]	CLK_M_OSC CLK_32KHZ (PER_CLKOUTM2 / 5859.375) TCLKIN CLK_RC32K CLK_32K_RTC	pd_wkup_timer1_gclk from PRCM

(1) PICLKTIMER must be less than PICLKOCP/4.

Copyright © 2011, Texas Instruments Incorporated

20.2.3 Functional Description

The general-purpose timer is an upward counter. It supports 3 functional modes:

- Timer mode
- Capture mode
- Compare mode

By default, after core reset, the capture and compare modes are disabled.

20.2.3.1 Timer Mode Functionality

The timer is an upward counter that can be started and stopped at any time through the Timer Control Register (TCLR ST bit). The Timer Counter Register (TCRR) can be loaded when stopped or on the fly (while counting). TCRR can be loaded directly by a TCRR Write access with the new timer value. TCRR can also be loaded with the value held in the Timer Load Register TLDR by a trigger register (TTGR) Write access. The TCRR loading is done regardless the TTGR written value. The timer counter register TCRR value can be read when stopped or captured on the fly by a TCRR Read access. The timer is stopped and the counter value set to “0” when the module’s reset is asserted. The timer is maintained in stop after reset is released. When the timer is stopped TCRR is frozen and it can be restarted from the frozen value unless TCRR has been reloaded with a new value.

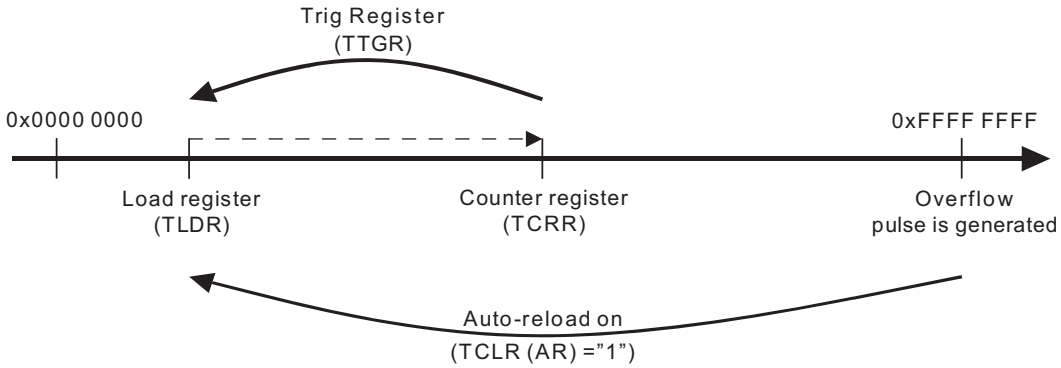
In the one shot mode (TCLR AR bit =”0”), the counter is stopped after counting overflow (counter value remains at zero).

When the auto-reload mode is enabled (TCLR AR bit =”1”), the TCRR is reloaded with the Timer Load Register (TLDR) value after a counting overflow.

It is not recommended to put the overflow value (0xFFFFFFFF) in TLDR because it can lead to undesired results.

An interrupt can be issued on overflow if the overflow interrupt enable bit is set in the timer Interrupt Enable Register (TIER OVF_IT_ENA bit =”1”). A dedicated output pin (PORTIMERPWM) is programmed through TCLR (TRG and PT bits) to generate one positive pulse (prescaler duration) or to invert the current value (toggle mode) when an overflow occurs.

Figure 20-26. TCRR Timing Value



20.2.3.1.1 1 ms Tick Generation

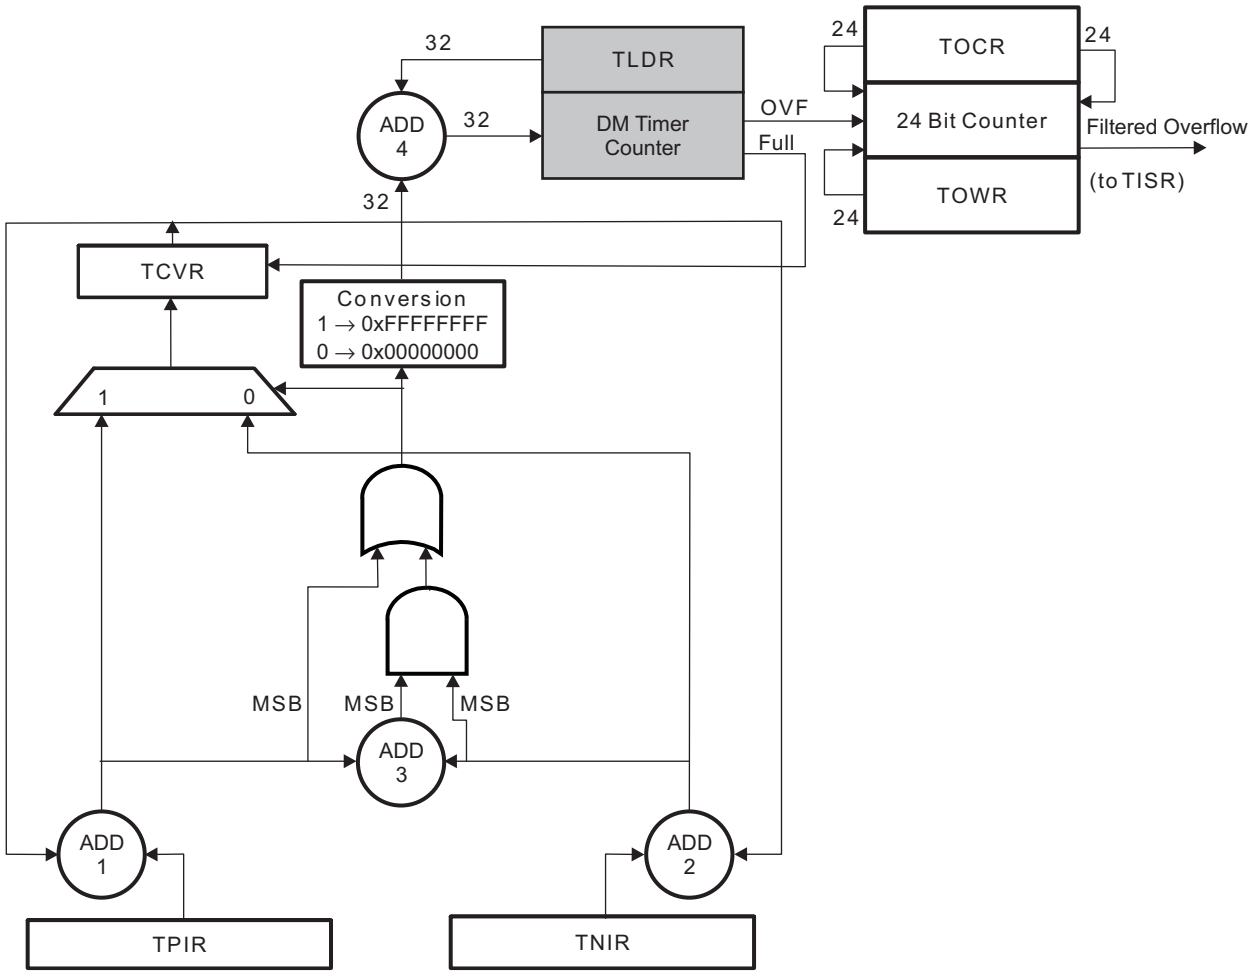
To minimize the error between a true 1ms tick and the tick generated by the 32768 Hz timer the sequencing of the sub-1ms periods and the over-1ms periods must be shuffled.

An additional block (1ms block) is used to correct this error.

In this implementation the increment sequencing is automatically managed by the timer to minimize the error. The value of the Timer Positive Increment register (TPIR) and Timer Negative Increment register (TNIR) only need to be defined by the user. Auto adaptation mechanism is used to simplify the programming model.

Copyright © 2011, Texas Instruments Incorporated

Figure 20-27. 1ms Module Block Diagram



The TPIR, TNIR, TCVR and adders Add1..3 are used to define whether next value loaded in the TCRR will be value of the TLDR (sub-period value) or the value of TLDR – 1 (over-period value).

The following table shows the value loaded in TCRR according to the sign of the result of Add1, Add2 and Add3. MSB = '0' means a positive value, MSB = '1' means a negative value.

Table 20-30. Value Loaded in TCRR to Generate 1ms Tick

Add1 MSB	Add2 MSB	Add3 MSB	TCRR
0	0	0	TLDR
0	0	1	TLDR
0	1	0	TLDR
0	1	1	TLDR - 1
1	0	0	N.A.
1	0	1	N.A.
1	1	0	TLDR - 1
1	1	1	TLDR - 1

The values of TPIR and TNIR registers are calculated with formula:

Positive Increment Value = ((INTEGER[Fclk * Ttick] + 1) * 1e6) - (Fclk * Ttick * 1e6)

Negative Increment Value = (INTEGER[Fclk * Ttick] * 1e6) - (Fclk * Ttick * 1e6)

where:

Copyright © 2011, Texas Instruments Incorporated

Fclk – clock frequency (KHz)

Ttick – tick period (ms)

The Timer Overflow Counter Register (TOCR) and the Timer Overflow Wrapping Register (TOWR) are used for interrupt filtering. When timer overflows it increments the 24 bit TOCR register. When 24 bit TOCR register values matches the value in the 24 bit TOWR register and timer overflow is asserted, the TOCR is reset and an interrupt is generated to TISR.

With the Conversion block, in reset state (Positive Increment register, Negative Increment register and Counter Value register are all zeroed) the programming model and the behavior of the DMtimer_dmc1ms remain unchanged.

For 1 ms tick with a 32768-Hz clock:

TPIR = 232000

TNIR = -768000

TLDR = 0xFFFFFFE0

NOTE: Any value of the tick period can be generated with appropriate value of the TPIR, TNIR and TLDR registers.

By default the TPIR, TNIR, TCVR, TOCR, TOWR registers and the associated logic are in reset mode (all 0s) and have no action on the programming model of the DMtimer_dmc1ms.

20.2.3.2 Capture Mode Functionality

The timer value in TCRR can be captured and saved in TCAR1 or TCAR2 function of the mode selected in TCLR through the field CAPT_MODE when a transition is detected on the module input pin (PIEVENTCAPT). The edge detection circuitry monitors transitions on the input pin (PIEVENTCAPT).

Rising transition, falling transition or both can be selected in TCLR (TCM bit) to trig the timer counter capture. The module sets the TISR (TCAR_IT_FLAG bit) when an active transition is detected and at the same time the counter value TCRR is stored in one of the timer capture registers TCAR1 or TCAR2 as follows:

- If TCLR's CAPT_MODE field is "0" then, on the first enabled capture event, the value of the counter register is saved in TCAR1 register and all the next events are ignored (no update on TCAR1 and no interrupt triggering) until the detection logic is reset or the interrupt status register is cleared on TCAR's position writing a "1" in it. .
- If TCLR's CAPT_MODE field is "1" then, on the first enabled captured event, the counter value is saved in TCAR1 register and, on the second enabled capture event, the value of the counter register is saved in TCAR2 register. If capture interrupt is enabled, the interrupt will be asserted on the second event capture. All the other events are ignored (no update on TCAR1/2 and no interrupt triggering) until the detection logic is reset or the interrupt status register is cleared on TCAR's position writing a "1" in it. This mechanism is useful for period calculation of a clock if that clock is connected to the PIEVENTCAPT input pin.

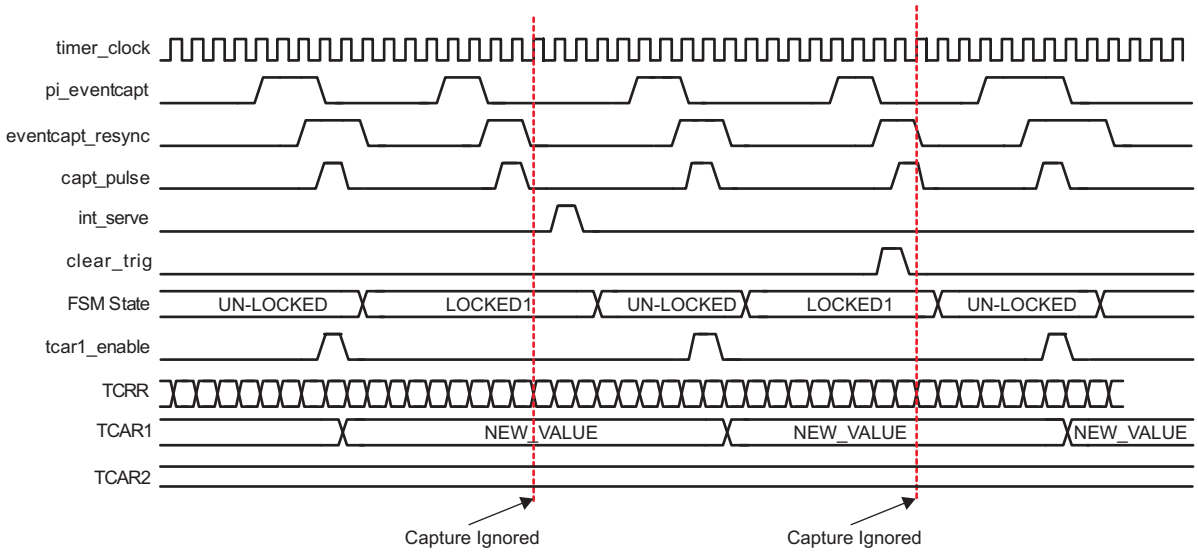
The edge detection logic is reset (a new capture is enabled) when the active capture interrupt is served - TCAR_IT_FLAG bit of TISR (previously '1') is cleared through a "1" written in it or when the edge detection mode bits TCLR (TCM bit) passed from the No Capture Mode detection to any other modes. The timer functional clock (input to prescaler) is used to sample the input pin (PIEVENTCAPT). Input negative or positive pulse can be detected when pulse time is above functional clock period. An interrupt can be issued on transition detection if the capture interrupt enable bit is set in the Timer Interrupt Enable Register TIER (TCAR_IT_ENA bit).

See the following examples:

In the next wave, the TCM value is "01" and CAPT_MODE is "0"- only rising edge of the PIEVENTCAPT will trigger a capture in TCAR and only TCAR1 will update.

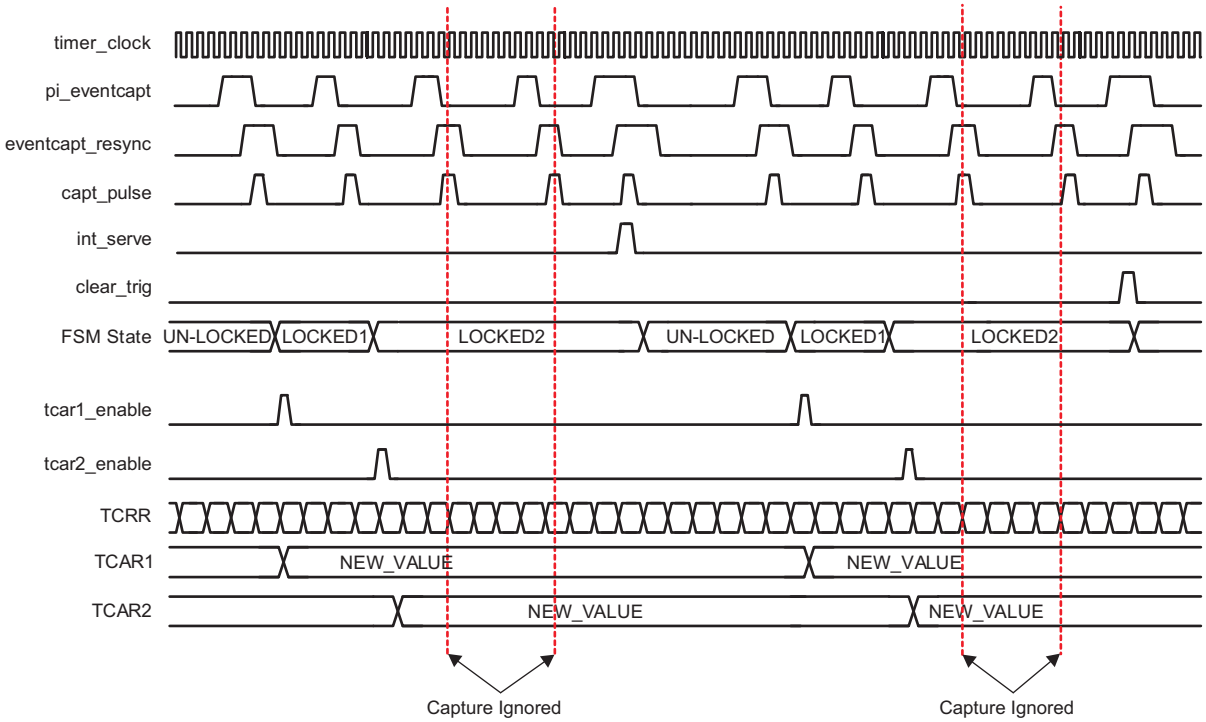
Copyright © 2011, Texas Instruments Incorporated

Figure 20-28. Capture Wave Example for CAPT_MODE 0



In the following example, the TCM value is “01” and CAPT_MODE is “1”- only rising edge of the PIEVENTCAPT will trigger a capture in TCAR1 on first enabled event and TCAR2 will update on the second enabled event.

Figure 20-29. Capture Wave Example for CAPT_MODE 1



20.2.3.3 Compare Mode Functionality

When Compare Enable TCLR (CE bit) is set to “1”, the timer value (TCRR) is permanently compared to the value held in timer match register (TMAR). TMAR value can be loaded at any time (timer counting or stop). When the TCRR and the TMAR values match, an interrupt can be issued if the TIER (MAT_IT_ENA bit) is set. The right programming way is to write a compare value in TMAR register before setting TCLR (CE bit) to avoid any unwanted interrupt due to a reset value matching effect.

Copyright © 2011, Texas Instruments Incorporated

The dedicated output pin (PORTIMERPWM) can be programmed through TCLR (TRG and PT bits) to generate one positive pulse (TIMER clock duration) or to invert the current value (toggle mode) when an overflow and a match occur.

20.2.3.4 Prescaler Functionality

A prescaler counter can be used to divide the timer counter input clock frequency. The prescaler is enabled when TCLR bit 5 is set (PRE). The 2n division ratio value (PTV) can be configured in the TCLR register.

The prescaler counter is reset when the timer counter is stopped or reloaded on the fly.

Table 20-31. Prescaler/Timer Reload Values Versus Contexts

Contexts	Prescaler Counter	Timer Counter
Overflow (when Auto-reload on)	reset	TLDR
TCRR Write	reset	TCRR
TTGR Write	reset	TLDR
Stop	reset	Frozen

20.2.3.5 Pulse-Width Modulation

The timer can be configured to provide a programmable pulse-width modulation (PORTIMERPWM) output. The PORTIMERPWM output pin can be configured to toggle on specified event. TCLR (TRG bits) determines on which register value the PORTIMERPWM pin toggles. Either overflow or match can be used to toggle the PORTIMERPWM pin, when a compare condition occurs.

In case of overflow and match mode, the match event will be ignored from the moment the mode was set-up until the first overflow event occurs

The TCLR (SCPWM bit) can be programmed to set or clear the PORTIMERPWM output signal while the counter is stopped or the triggering is off only. This allows fixing a deterministic state of the output pin when modulation is stopped. The modulation is synchronously stopped when TRG bit is cleared and overflow occurred.

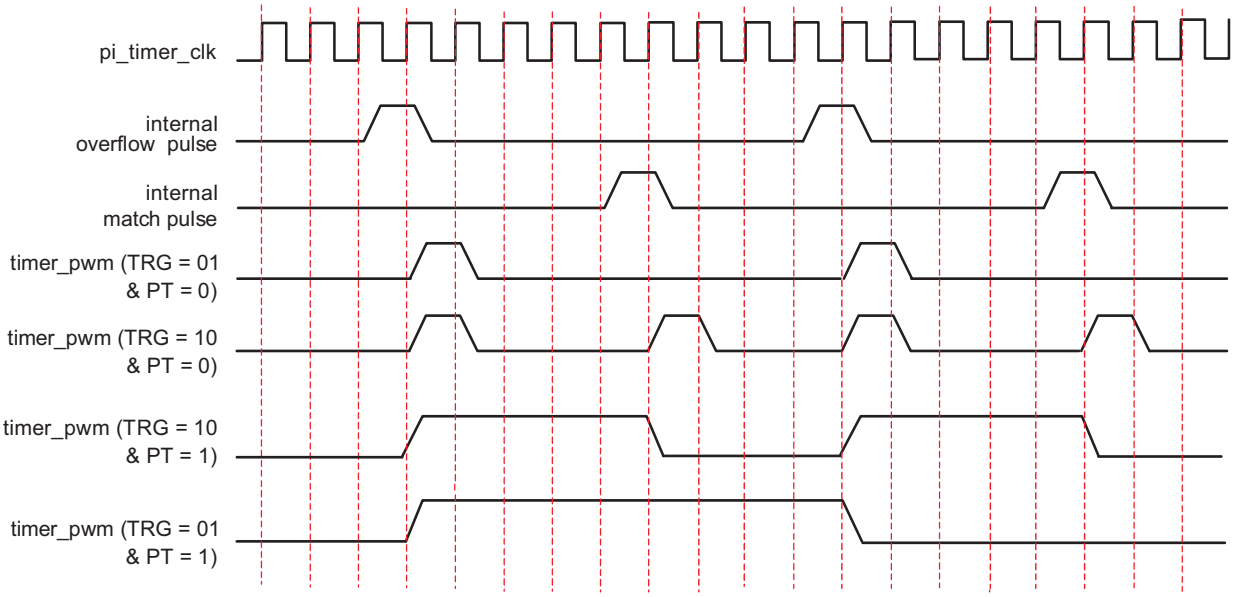
In the following timing diagram, the internal overflow pulse is set each time (0xFFFF FFFF – TLDR +1) value is reached, and the internal match pulse is set when the counter reaches TMAR register value. According to TCLR (TRG and PT bits) programming value, the timer provides pulse or PWM on the output pin (PORTIMERPWM).

The TLDR and TMAR registers must keep values smaller than the overflow value (0xFFFFFFFF) with at least 2 units. In case the PWM trigger events are both overflow and match, the difference between the values kept in TMAR register and the value in TLDR must be at least 2 units. When match event is used the compare mode TCLR (CE) must be set.

On the following wave TCLR (SCPWM bit) is set to ‘0’.

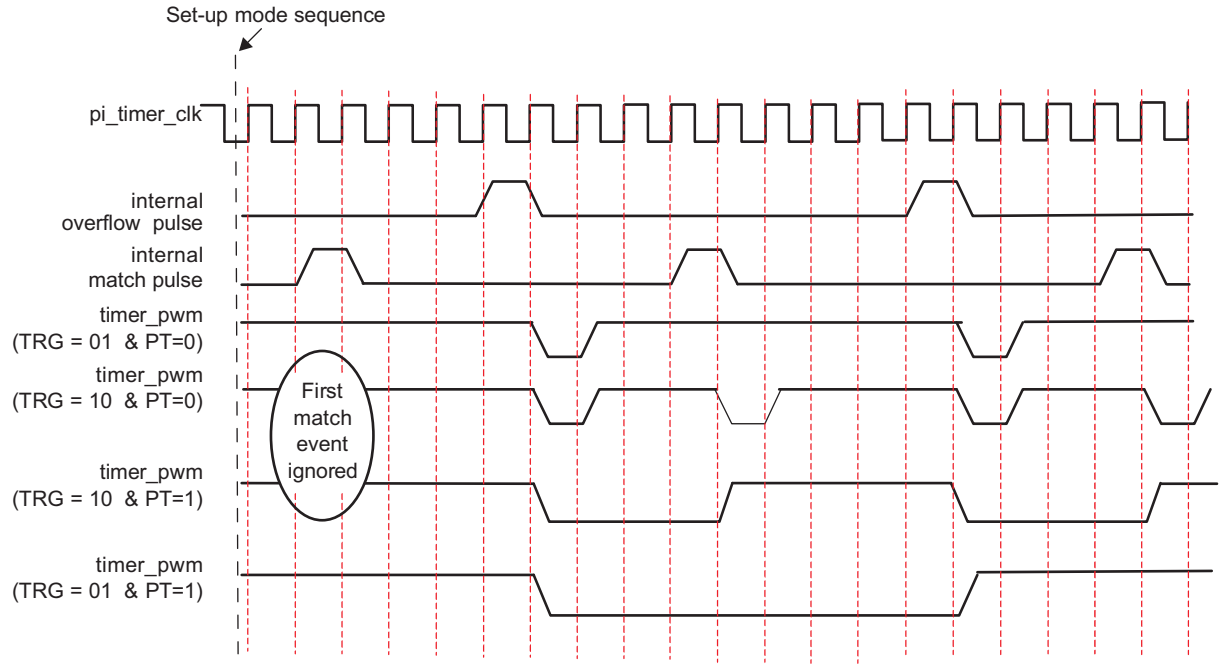
Copyright © 2011, Texas Instruments Incorporated

Figure 20-30. Timing Diagram of Pulse-Width Modulation, SCPWM Bit = 0



On the next wave TCLR (SCPWM bit) is set to ‘1’.

Figure 20-31. Timing Diagram of Pulse-Width Modulation, SCPWM Bit = 1



20.2.3.6 Timer Interrupt Control

The timer can issue an overflow interrupt, a timer match interrupt and a timer capture interrupt. Each internal interrupt sources can be independently enabled/disabled in the Interrupt Enable Register TIER. When the interrupt event has been issued the associated interrupt status bit is set in the Timer Status Register (TISR). The pending interrupt event is reset when the set status bit is overwritten by a “1” value. Reading the Interrupt Status Register and writing the value back allows fast acknowledge interrupt process.

Copyright © 2011, Texas Instruments Incorporated

20.2.3.7 Sleep Mode Request and Acknowledge

Upon a Sleep mode request issued by the host processor (the Idle Request PIOCPMIDLEREQ signal is active), the timer module will go in Sleep mode according to the IdleMode field of the System configuration register (see TIOCP_CFG and Ref. [4]).

If the IdleMode field sets No-Idle mode, the Timer does not go in Sleep mode and the Idle acknowledge signal (POROCPSIDLEACK) is never asserted.

If the IdleMode field sets Force-Idle mode, the timer goes in Sleep mode independently of the internal module state and the Idle acknowledge signal (POROCPSIDLEACK) is unconditionally asserted.

If the IdleMode field sets Smart-Idle mode, the timer module evaluates its internal capability to have the interface/functional clock switched off. Depending on the ClockActivity field setting the timer module evaluates the internal activity and asserts the Idle acknowledge signal (POROCPSIDLEACK), entering in Sleep mode, ready to issue a wake-up request.

The following table describes the Smart Idle behavior according to the clock activity setting:

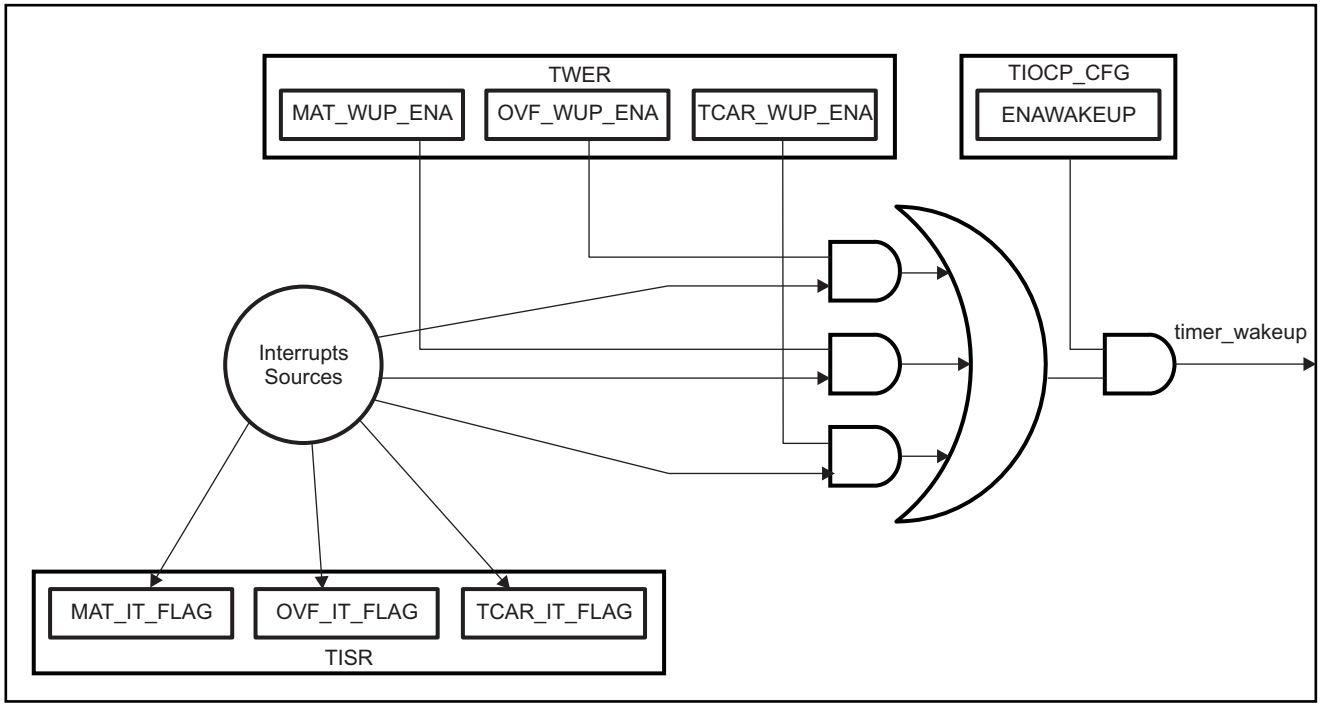
Table 20-32. SmartIdle - Clock Activity Field Configuration

Clock Activity	Functional Clock	OCP Clock	Module Behavior
11	ON	ON	The Idle acknowledge signal is asserted when there are no pending activities on the OCP clock domain, without evaluating the pending activities on the functional clock domain. (The module will enter in Sleep mode and if a pending interrupt event is finished during Idle mode the wake-up signal will be asserted).
10	ON	OFF	
01	OFF	ON	The Idle acknowledge signal is asserted when there are no pending activities on the functional and OCP clock domains (Improved latency in assertion of Idle acknowledge). The Wake-up capability of the module is disabled.
00	OFF	OFF	

Copyright © 2011, Texas Instruments Incorporated

This wake-up request is effectively sent only if the field ENAWAKEUP of TIOCP_CFG enables the timer wake-up capability. When the system is awaken, the Idle Request signal goes inactive and the wake-up request signal is also de-asserted.

Figure 20-32. Wake-up Request Generation



20.2.3.7.1 Wake-up Line Release

When the host processor receives wake-up request issued by the timer peripheral, the interface clock is re-activated: the host processor deactivates the PIOCPMIDLEREQ, the timer deactivates the POROCPSIDLEACK signal and then the host can read the corresponding bit in TISR to find out which interrupt source has trigged wake-up request. After acknowledging the wake-up request, the processor resets the status bit and releases the interrupt line by writing a '1' in the corresponding bit of the TISR register.

20.2.3.8 Timer Counting Rate

The dmtimer's counter is composed of a prescaler stage and a timer counter.

Ratio can be managed by accessing the ratio definition field of the control register (PTV and PRE of TCLR).

The timer rate is defined by:

- The value of the prescaler fields (PRE and PTV of TCLR register)
- The value loaded into the Timer Load Register (TLDR).

Table 20-33. Prescaler Clock Ratios Value

PRE	PTV	Divisor (PS)
0	X	1
1	0	2
1	1	4
1	2	8
1	3	16
1	4	32

Copyright © 2011, Texas Instruments Incorporated

Table 20-33. Prescaler Clock Ratios Value (continued)

PRE	PTV	Divisor (PS)
1	5	64
1	6	128
1	7	256

The timer rate equation is as follows:

(0xFFFF FFFF – TLDR + 1) x timer Clock period x Clock Divider (PS)

With timer Clock period = 1/ timer Clock frequency and PS = 2(PTV + 1).

As example, if we consider a timer clock input of 32 KHz, with a PRE field equals to “0”, the timer output period is:

Table 20-34. Value and Corresponding Interrupt Period

TLDR	Interrupt Period
0x0000 0000	37 h
0xFFFF 0000	2 s
0xFFFF FFF0	500 us
0xFFFF FFFE	62.5 us

20.2.3.9 Dual Mode Timer Under Emulation

During emulation mode (when PINSUSPENDN signal is active), the timer can/cannot continue running according to the value of the EmuFree bit of the timer OCP configuration register (TIOCP_CFG).

If EmuFree is 1, timer execution is not stopped and, regardless of the value of PINSUSPENDN signal, and the interrupt assertion is still generated when overflow is reached.

If EmuFree is 0, counters (prescaler/timer) are frozen and an increment start occurs again as soon as PINSUSPENDN becomes inactive. The asynchronous input pin is internally synchronized on 2 TIMER clock rising edges.

20.2.4 Use Cases

20.2.5 DMTIMER_1MS Registers

Table 20-35 lists the memory-mapped registers for the DMTIMER_1MS. All register offset addresses not listed in Table 20-35 should be considered as reserved locations and the register contents should not be modified.

Table 20-35. DMTIMER_1MS REGISTERS

Offset	Acronym	Register Description	Section

20.2.5.3 TISTAT Register (offset = 14h) [reset = 0h]

This register provides status information about the module, excluding the interrupt status information

TISTAT is shown in Figure 20-35 and described in Table 20-38.

20.3 RTC_SS

20.3.1 Introduction

The real-time clock is a precise timer which can generate interrupts on intervals specified by the user. Interrupts can occur every second, minute, hour, or day. The clock itself can track the passage of real time for durations of several years, provided it has a sufficient power source the whole time.

The basic purpose for the RTC is to keep time of day. The other equally important purpose of RTC is for Digital Rights management. Some degree of tamper proofing is needed to ensure that simply stopping, resetting, or corrupting the RTC does not go unnoticed so that if this occurs, the application can re-acquire the time of day from a trusted source. The final purpose of RTC is to wake the rest of chip up from a power down state.

Alarms are available to interrupt the CPU at a particular time, or at periodic time intervals, such as once per minute or once per day. In addition, the RTC can interrupt the CPU every time the calendar and time registers are updated, or at programmable periodic intervals.

20.3.1.1 Features

The real-time clock (RTC) provides the following features:

- 100-year calendar (xx00 to xx99)
- Counts seconds, minutes, hours, day of the week, date, month, and year with leap year compensation
- Binary-coded-decimal (BCD) representation of time, calendar, and alarm
- 12-hour clock mode (with AM and PM) or 24-hour clock mode
- Alarm interrupt
- Periodic interrupt
- Single interrupt to the CPU
- Supports external 32.768-kHz crystal or external clock source of the same frequency

20.3.1.2 Unsupported RTC Features

This device supports only a single RTC external wake-up event.

Copyright © 2011, Texas Instruments Incorporated

20.3.2 Integration

This device includes a Real-Time Clock Subsystem (RTCSS) module to allow easy tracking of time and date and the generation of real time alarms.

20.3.2.1 RTC Connectivity Attributes

The general connectivity for the RTC module in the device is shown in Table 20-56.

Table 20-56. RTC Module Connectivity Attributes

Attributes	Type
Power Domain	RTC
Clock Domain	PD_RTC_L4_RTC_GCLK (Interface/OCP) PD_RTC_RTC32KCLK (Func) CLK_32K_RTC (Func)
Reset Signals	RTC_DOM_RST_N
Idle/Wakeup Signals	Smart Idle
Interrupt Requests	4 Interrupts Alarm interrupt to MPU Subsystem (RTCINT) and WakeM3 Timer interrupt to MPU Subsystem (RTCALARMINT) and WakeM3 Alarm wakeup to WakeM3 Timer wakeup to WakeM3
DMA Requests	None
Physical Address	L4 Wakeup slave port

20.3.2.2 RTC Clock and Reset Management

The RTC functional clock (c32khz_clk input) is sourced by default from the CLK32_KHZ clock derived from the Peripheral PLL. It can also be sourced from the 32-KHz oscillator through a clock mux within and controlled by the RTC_SS.

Table 20-57. RTC Clock Signals

Clock Signal	Max Freq	Reference / Source	Comments
ocp_clk (Interface clock)	100 MHz	CORE_CLKOUTM4 / 2	pd_rtc_l4_rtc_gclk From PRCM
rtc_32K_clk_rtc_32k_clk (Oscillator functional clock)	32.768 KHz	OSC1_IN	CLK_32K_RTC From OSC1_IN
rtc_32k_clk_rtc_32k_aux_clk (Internal functional clock)	32.768 KHz	PER_CLKOUTM2 / 5859.3752	pd_rtc_rtc_32kclk From PRCM

20.3.2.3 RTC Pin List

The RTC module does not include any external interface pins.

Table 20-58. RTC Pin List

Pin	Type	Description
RTC_PORz	I	RTC Power On Reset
EXT_WAKEUP	I	External wakeup
PMIC_POWER_EN	O	Power enable control for external power management IC
Analog Signals		
ENZ_KALDO_1P8V	I	Enable1.8V LDO
VDDS_RTC	P	1.8V Voltage Supply

20.3.3 Functional Description

This section defines the module interrupt capabilities and requirements.

20.3.3.1 Functional Block Diagram

Figure 20-53 shows the RTC module block diagram. Figure 20-54 shows a functional block diagram of the RTC.

Figure 20-53. RTC Block Diagram

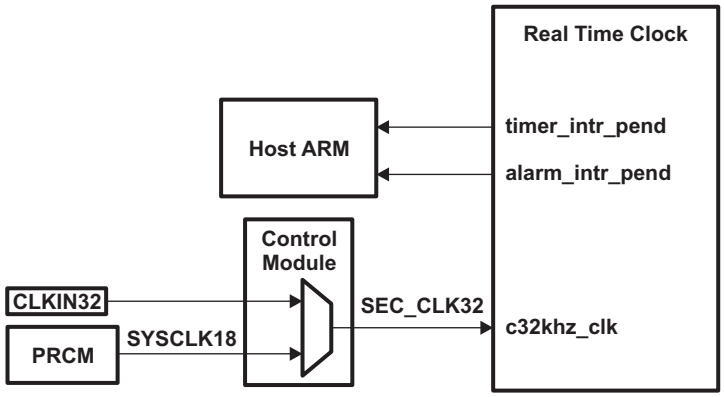

Figure 20-54. RTC Functional Block Diagram

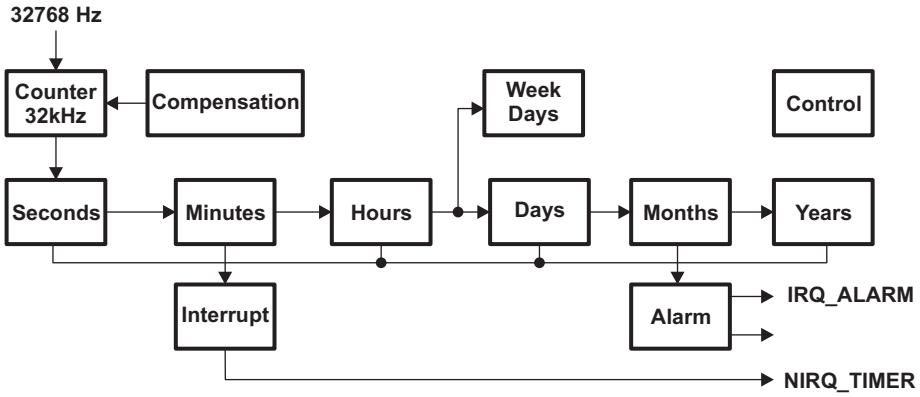

20.3.3.2 Clock Source

The clock reference for the RTC is an internal 32.768-kHz crystal or an external clock source of the same frequency. The source for the RTC reference clock may be provided by a crystal or by an external clock source. The RTC has an internal oscillator buffer to support direct operation with a crystal. The crystal is connected between pins RTC_XTALIN and RTC_XTALOUT. RTC_XTALIN is the input to the on-chip oscillator and RTC_XTALOUT is the output from the oscillator back to the crystal. The oscillator can be enabled or disabled by using the control module register rcosc_ctrl. See for Section 9.3.1.14 more information. For more information about the RTC crystal connection, see your device-specific data manual.

An external 32.768-kHz clock source may be used instead of a crystal. In such a case, the clock source is connected to RTC_XTALIN, and RTC_XTALOUT is left unconnected.

If the RTC is not used, the RTC_XTALIN pin should be held low and RTC_XTALOUT should be left unconnected. The RTC_disable bit in the control register (CTRL_REG) can be set to save power; however, the RTC_disable bit should not be cleared once it has been set. If the application requires the RTC module to stop and continue, the STOP_RTC bit in CTRL_REG should be used instead.

20.3.3.3 Signal Descriptions

Table 20-59 lists the signals and their descriptions for the RTC.

Table 20-59. RTC Signals

Signal	I/O	Description
RTC_XTALIN	I	RTC time base input signal. RTC_XTALIN can either be driven with a 32.768-kHz reference clock, or RTC_XTALIN and RTC_XTALOUT can be connected to an external crystal. This signal is the input to the RTC internal oscillator.
RTC_XTALOUT	O	RTC time base output signal. RTC_XTALOUT is the output from the RTC internal oscillator. If a crystal is not used as the time base for RTC_XTALIN, RTC_XTALOUT should be left unconnected.

Copyright © 2011, Texas Instruments Incorporated

20.3.3.4 Interrupt Support

20.3.3.4.1 CPU Interrupts

The RTC generates two interrupt outputs:

- timer_intr (RTCINT) is a timer interrupt.
- alarm_intr (RTCALARMINT) is an alarm interrupt.

NOTE: Both interrupt outputs support high-level and high-pulse.

20.3.3.4.2 Interrupt Description

20.3.3.4.2.1 Timer Interrupt RTCINT (timer_intr)

The timer interrupt can be generated periodically: every second, every minute, every hour, or every day (see INTERRUPTS_REG[1:0] for a description of how to set this up). The IT_TIMER bit of the interrupt register enables this interrupt. The timer interrupt is active-low.

The RTC_STATUS_REG[5:2] are only updated at each new interrupt and occur according to Table 20-60. For example, bit 2 (SEC) will always be set when one second has passed. It will also be set when one minute has passed since the completion of one minute also marks the completion of one second (from 59 seconds to 60 seconds). The same holds true for hours and days: each of them will also correspond to the passing of a second.

Conversely, bit 5 (DAY) will always be set when a day has passed. It might also be set when an hour, minute, or second has passed. However, this only occurs when the elapsed hour, minute, or second corresponds to the start of a new day.

Table 20-60. Interrupt Trigger Events

	One day has passed	One hour has passed	One minute has passed	One second has passed
STATUS_REG[5] (DAY)	1	0/1[(1)]	0/1[(1)]	0/1[(1)]
STATUS_REG[4] (HOUR)	1	1	0/1[(1)]	0/1[(1)]
STATUS_REG[3] (MIN)	1	1	1	0/1[(1)]
STATUS_REG[2] (SEC)	1	1	1	1

(1) This event is only triggered when the elapsed time unit (for example, Day) corresponds to the passage of another unit (for example, Seconds). For example, when the clock ticks from 00:23:59:59 (days : hours : minutes : seconds) to 01:00:00:00.

20.3.3.4.2.2 Alarm Interrupt RTCALARMINT (alarm_intr)

The alarm interrupt can be generated when the time set into TC ALARM registers is exactly the same as in the TC registers. This interrupt is then generated if the IT_ALARM bit of the interrupts register is set. This interrupt is low-level sensitive. RTC_STATUS_REG[6] indicates that IRQ_ALARM_CHIP has occurred. This interrupt is disabled by writing ‘1’ into the RTC_STATUS_REG[6].

To set up an alarm:

- Modify the ALARM_SECONDS, ALARM_MINUTES, ALARM_HOURS, ALARM_DAY, ALARM_WEEK, ALARM_MONTH, and ALARM_YEAR registers to the exact time you want an alarm to generate.
- Set the IT_ALARM bit in the RTC_INTERRUPTS register to enable the alarm interrupt.

Copyright © 2011, Texas Instruments Incorporated

20.3.3.5 Programming/Usage Guide

20.3.3.5.1 Time/Calendar Data Format

The time and calendar data in the RTC is stored as binary-coded decimal (BCD) format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent. Although most of the time/calendar registers have 4 bits assigned to each BCD digit, some of the register fields are shorter since the range of valid numbers may be limited. For example, only 3 bits are required to represent the day of the week (WEEKS_REG) since only BCD numbers 1 through 7 are required. The following time and calendar registers are supported (BCD Format):

Note that the ALARM registers which share the names above also share the same BCD formatting.

- SECOND - Second Count (00-59)
- MINUTE - Minute Count (00-59)
- HOUR - Hour Count (12HR: 01-12; 24HR: 00-23)
- DAY - Day of the Month Count (01-31)
- WEEK - Day of the Week (0-6: SUN = 0)
- MONTH - Month Count (01-12; JAN = 1)
- YEAR - Year Count (00-99)

20.3.3.5.2 Register Access

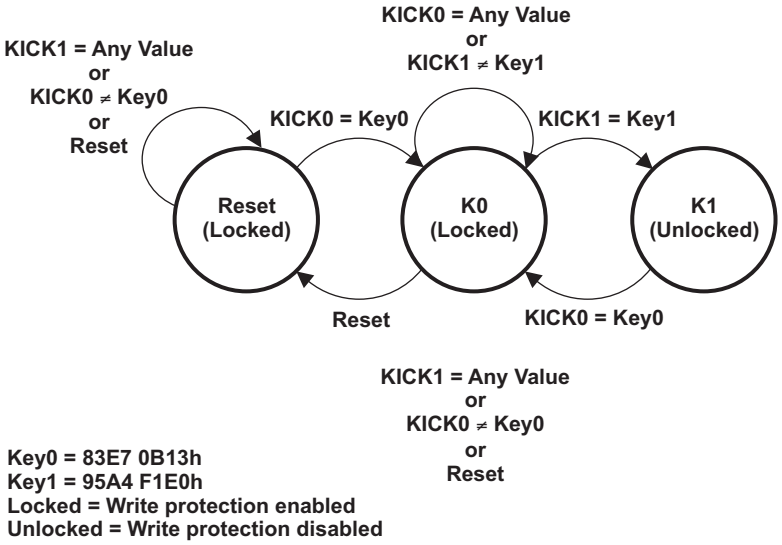
The three register types are as follows and each has its own access constraints:

- TC and TC alarm registers
- General registers
- Compensation registers

20.3.3.5.3 OCP MMR Spurious WRT Protection

The module also contains a kicker mechanism (Figure 20-55) to prevent any spurious writes from changing the register values. This mechanism requires two MMR writes to the Kick0 and Kick1 registers with exact data values before the kicker lock mechanism is released. Once released, the MMRs are writeable. The Kick0 data is 83E7 0B13h; the Kick1 data is 95A4 F1E0h. Note that it remains in an unlocked state until an OCP reset or invalid data pattern is written to one of the Kick0 or Kick1 registers.

Figure 20-55. Kick Register State Machine Diagram



Copyright © 2011, Texas Instruments Incorporated

- S0 is the Reset/Idle state
- S1 is an OCP wrt cycle of 83E7 0B13h at Kick0 completed state
- S2 is the UNLOCK MMR WRT state
- S0 -> S1 when OCP wrt cycle of 83E7 0B13h at Kick0
- S1 -> S2 when OCP wrt cycle of 95A4 F1E0h at Kick1
- S1 -> S0 when OCP reset event
- S2 -> S0 when OCP reset event OR OCP wrt cycle of NOT 83E7 0B13h at Kick0 OR OCP wrt cycle at Kick1
- S2 ->S1 when OCP wrt cycle of 83E7 0B13h at Kick0

20.3.3.5.4 Reading the Timer/Calendar (TC) Registers

The TC registers have a read-show register. The reading of the Seconds register will update all of the TC registers. For example, the Year will only get updated on a reading of the Seconds register. The time/calendar registers are updated every second as the time changes. During a read of the SECONDS register, the RTC copies the current values of the time/date registers into shadow read registers. This isolation assures that the CPU can capture all the time/date values at the moment of the SECONDS read request and not be subject to changing register values from time updates.

If desired, the RTC also provides a one-time-triggered minute-rounding feature to round the MINUTE:SECOND registers to the nearest minute (with zero seconds). This feature is enabled by setting the ROUND_30S bit in the control register (CTRL); the RTC automatically rounds the time values to the nearest minute upon the next read of the SECONDS register.

NOTE: Software should always read the Seconds register first. However, the software does not have to poll any status bit to determine when to read the TC registers. Table 20-61 defines the TC set that gets shadowed.

Table 20-61. RTC Register Names and Values

Time Unit	Range	Remarks
Year	00 to 99	
Month	01 to 12	
Day	01 to 31	Months 1, 3, 5, 7, 8, 10, 12
	01 to 30	Months 4, 6, 9, 11
	01 to 29	Month 2 (leap year)
	01 to 28	Month 2 (common year)
Week	00 to 06	Day of week
Hour	00 to 23	24 hour mode
	01 to 12	AM/PM mode
Minute	00 to 59	
Seconds	00 to 59	

20.3.3.5.4.1 Rounding Seconds

Time can be rounded to the closest minute, by setting the ROUND_30S bit of the control register. When this bit is set, TC values are set to the closest minute value at the next second. The ROUND_30S bit will be automatically cleared when rounding time is performed.

Example:

- If current time is 10H59M45S, round operation will change time to 11H00M00S.
- If current time is 10H59M29S, round operation will change time to 10H59M00S.

Copyright © 2011, Texas Instruments Incorporated

20.3.3.5.5 Modifying the TC Registers

To write correct data from/to the TC and TC alarm registers and read the TC alarm registers, the ARM must first read the BUSY bit of the STATUS register until BUSY is equal to zero. Once the BUSY flag is zero, there is a 15 µs access period in which the ARM can program the TC and TC alarm registers. Once the 15 µs access period passes, the BUSY flag has to be read again from the STATUS register as described previously. If the ARM accesses the TC registers outside of the access period, then the access is not guaranteed.

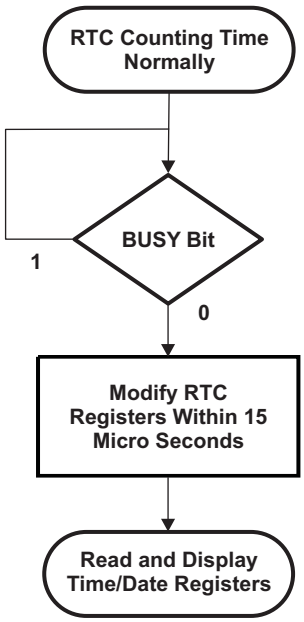
The ARM can access the STATUS_REG and CTRL_REG at any time, with the exception of CTRL_REG[5] which can only be changed when the RTC is stopped. The ARM can stop the RTC by clearing the STOP_RTC bit of the control register. After clearing this bit, the RUN bit in the STATUS_REG (bit 1) needs to be checked to verify the RTC has in fact stopped. Once this is confirmed, the TC values can be updated. After the values have been updated, the RTC can be re-started by resetting the STOP_RTC bit.

NOTE: After writing to a TC register, the user must wait 4 OCP clock cycles before reading the value from the register. If this wait time is not observed and the TC register is accessed, then old data will be read from the register.

CAUTION

In order to remove any possibility of interrupting the register's read process, thus introducing a potential risk of violating the authorized 15-microsecond access period, it is strongly recommended that you disable all incoming interrupts during the register read process.

Figure 20-56. Flow Control for Updating RTC Registers



20.3.3.5.5.1 General Registers

The ARM can access the STATUS_REG and the CTRL_REG at any time (except the CTRL_REG[5] bit which must be changed only when the RTC is stopped). For the INTERRUPTS_REG, the ARM should respect the available access period to prevent spurious interrupt.

Copyright © 2011, Texas Instruments Incorporated

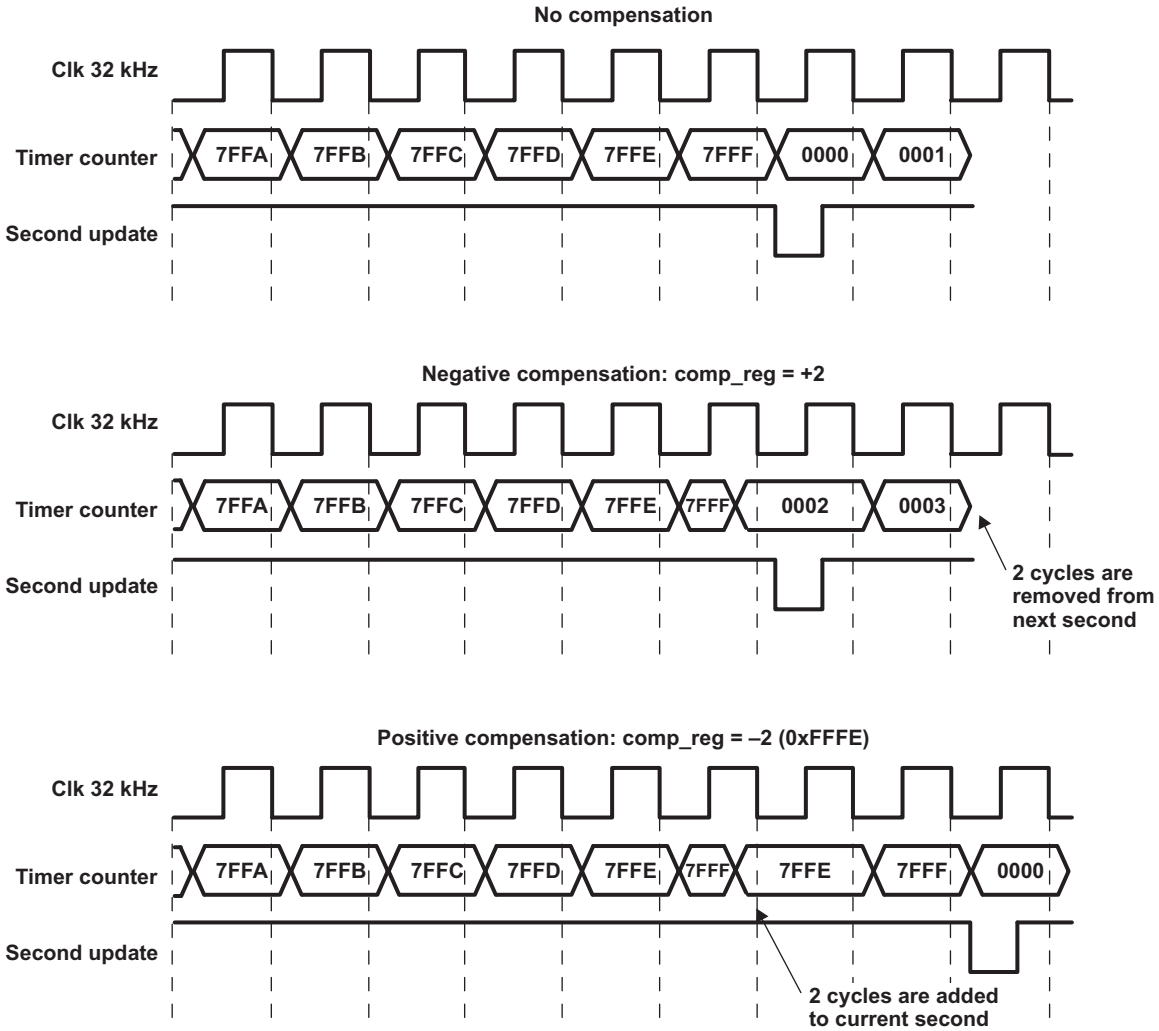
The RTC_DISABLE bit of the CTRL register must only be used to completely disable the RTC function. When this bit is set, the 32 kHz clock is gated, and the RTC is frozen. From this point, resetting this bit to zero can lead to unexpected behavior. In order to save power, this bit should only be used if the RTC function is unwanted in the application.

20.3.3.5.6 Crystal Compensation

To compensate for any inaccuracy of the 32 kHz oscillator, the ARM can perform a calibration of the oscillator frequency, calculate the drift compensation versus one-hour period, and load the compensation registers with the drift compensation value. Auto compensation is enabled by AUTO_COMP_EN bit in the RTC_CTRL register. If the COMP_REG value is positive, compensation occurs after the second change event. COMP_REG cycles are removed from the next second. If the COMP_REG value is negative, compensation occurs before the second change event. COMP_REG cycles are added to the current second. This enables compensation with a 1 32-kHz period accuracy each hour. The waveform below summarizes positive and negative compensation effect.

Access to the COMP_MSB_REG and COMP_LSB_REG registers must respect the available access period. These registers should not be updated during compensation (first second of each hour), but it is alright to update them during the second preceding a compensation event. For example, the ARM could load the compensation value into these registers after each hour event, during an available access period.

Figure 20-57. Compensation Illustration



Copyright © 2011, Texas Instruments Incorporated

20.3.3.6 Scratch Registers

The RTC provides three general-purpose registers (SCRATCHx_REG) that can be used to store 32-bit words -- these registers have no functional purpose for the RTC. Software using the RTC may find the SCRATCHx registers to be useful in indicating RTC states. For example, the SCRATCHx_REG registers may be used to indicate write-protection lock status or unintentional power downs. To indicate write-protection, the software should write a unique value to one of the SCRATCHx_REG registers when write-protection is disabled and another unique value when write-protection is enabled again. In this way, the lock-status of the registers can be determined quickly by reading the SCRATCH register. To indicate unintentional power downs, the software should write a unique value to one of the SCRATCHx_REG registers when RTC is configured and enabled. If the RTC is unintentionally powered down, the value written to the SCRATCH register is cleared. For more information, see the registers section.

20.3.3.7 Power Management

The RTC supports the power idle protocol. It has two SWakeup ports: one for the alarm event and one for a timer event.

When the RTC is in IDLE mode, the OCP clock is turned off and the 32 kHz clock remains on. The time and calendar continue to count in IDLE mode. When the RTC is placed back in FUNCTIONAL mode, the TC registers can be read.

The Alarm SWakeup event can be used to wakeup the RTC when it is in IDLE state. In order to do so, the alarm needs to be set and enabled before RTC enters the IDLE state. Once this is done, the SWakeup will occur when the alarm event triggers.

NOTE: Since SWakeup is not periodic, using it to wake up the RTC when in IDLE state is not recommended. Please use Alarm SWakeup instead.

20.3.3.8 Reset Considerations

When the device is initially powered on, the RTC may issue spurious interrupt signals to the CPU. To avoid issues, a software reset should be performed on the RTC module before the CPU interrupt controller is initialized. Also, see the register summary table in the registers section for reset states of each register.

20.3.3.9 Power Management—System Level (PMIC Mode)

The RTC genertates pmic_pwr_enable control which can be used to control an external PMIC.

Table 20-62. pmic_pwr_enable Description

Port	Direction	Function
rtc_por_arst_n	Input	Not optional. RTC true power on domain reset. Only assert when RTC has lost power. Always de-assert when RTC voltage is greater than Vmin. The port remains de-asserted during normal operations.
pmic_pwr_enable	Output	Optional. Can be used to control an external PMIC. 0 = OFF 1 = ON (reset state) ON → OFF (Turn OFF) By ALARM2 event OFF → ON (Turn ON) By ALARM event OR ext_wakeup<n> event
ext_wakeup0	Input	
ext_wakeup1	Input	
ext_wakeup2	Input	
ext_wakeup3	Input	

Copyright © 2011, Texas Instruments Incorporated

20.3.4 Use Cases

The following list includes high-level steps to start using the RTC:

1. Enable the module clock domains (see the Integration section for details on which clock domain).
2. Enable the RTC module using CTRL_REG.RTC_disable.
3. Enable the 32K clock from PER PLL.
4. Write to the kick registers (KICK0R, KICK1R) in the RTC.
5. Do the required timer setup in the RTCSS.
6. Start the RTC (in CTRL_REG.STOP_RTC).

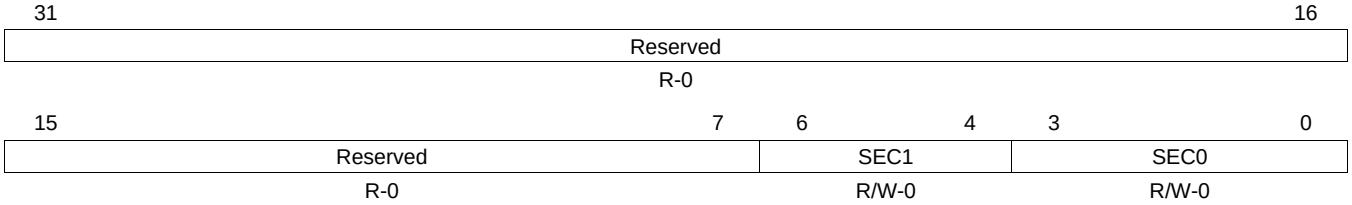
20.3.5.1 Seconds Register (SECONDS_REG)

The SECONDS_REG is used to program the required seconds value of the current time. Seconds are stored as BCD format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent. If the seconds value is 45, then the value of SEC0 is 5 and value of SEC1 is 4.

Figure 20-58. Seconds Register (SECONDS_REG)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

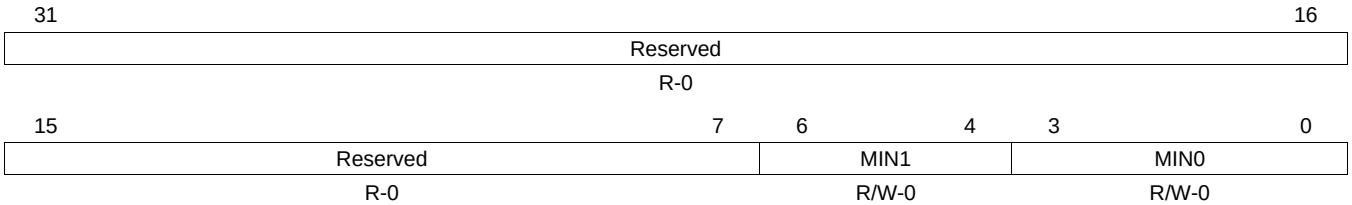
Table 20-64. Seconds Register (SECONDS_REG) Field Descriptions

Bit	Field	Value	Description
31-7	Reserved	0	Reserved.
6-4	SEC1	0-5h	2nd digit of seconds, Range is 0 to 5
3-0	SEC0	0-9h	1st digit of seconds, Range is 0 to 9

20.3.5.2 Minutes Register (MINUTES_REG)

The MINUTES_REG is used to program the minutes value of the current time. Minutes are stored as BCD format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent. If the minutes value is 32, then the value of MIN0 is 2 and value of MIN1 is 3.

Figure 20-59. Minutes Register (MINUTES_REG)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 20-65. Minutes Register (MINUTES_REG) Field Descriptions

Bit	Field	Value	Description

20.3.5.3 Hours Register (HOURS_REG)

The HOURS_REG is used to program the hours value of the current time. Hours are stored as BCD format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent. In 24Hr time mode if you want to set the hour as 18, then HOUR0 is set as 8 and HOUR1 is set as 1.

Figure 20-60. Hours Register (HOURS_REG)

3-0	HOUR0	0-9h	1st digit of hours, Range is 0 to 9

20.3.5.4 Days of the Month Register (DAYS_REG)

The DAYS_REG is used to program the day of the month value of the current date. Days are stored as BCD format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent. If the day value of the date is 28, DAY0 is set as 8 and DAY1 is set as 2.

Figure 20-61. Days of the Month Register (DAYS_REG)

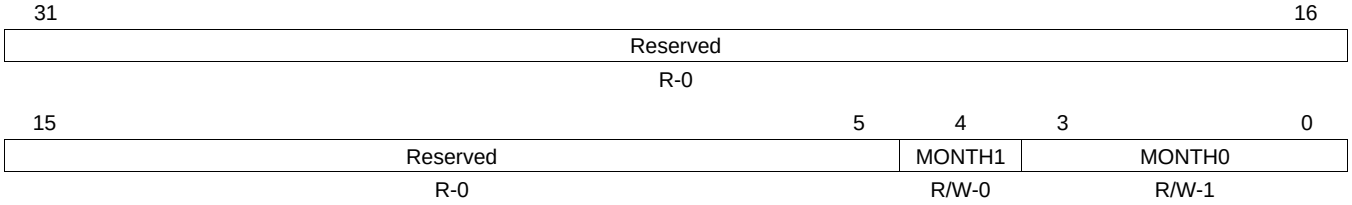
20.3.5.5 Month Register (MONTHS_REG)

The MONTHS_REG is used to set the month in the year value of the current date. Months are stored as BCD format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent.

NOTE: Usual notation is taken for month value:

- 01 => January
- 02 => February
- ...
- 12 => December

Figure 20-62. Month Register (MONTHS_REG)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

4	MONTH1	0-1h	2nd digit of months, Range is 0 to 1
3-0	MONTH0	0-9h	1st digit of months, Range is 0 to 9

20.3.5.6 Year Register (YEARS_REG)

The YEARS_REG is used to program the year value of the current date. The year value is represented by only the last 2 digits and is stored as BCD format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent. The year 1979 is programmed as 79 with YEAR0 set as 9 and YEAR1 set as 7.

3-0	YEAR0	0-9h	1st digit of years, Range is 0 to 9

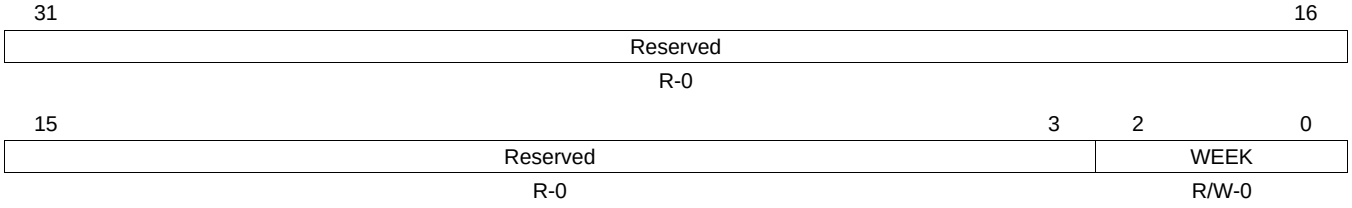
Copyright © 2011, Texas Instruments Incorporated

20.3.5.7 Day of the Week Register (WEEKS_REG)

The WEEKS_REG is used to program the day of the week value of the current date. The day of the week is stored as BCD format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent.

NOTE: Sunday is treated as 0, Monday 1, and ending at Saturday with 6.

Figure 20-64. Day of the Week Register (WEEKS_REG)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

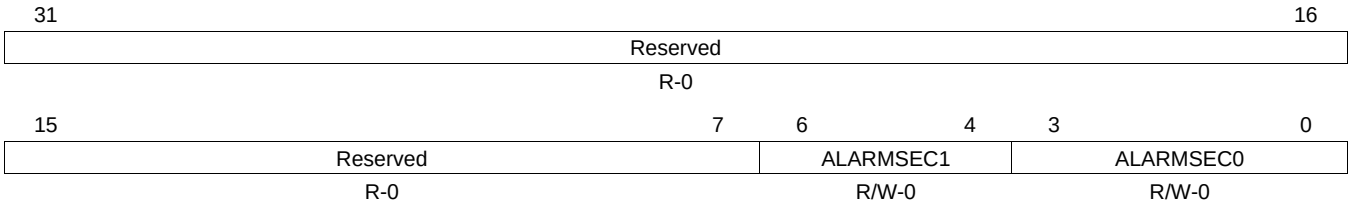
Bit	Field	Value	Description
31-3	Reserved	0	Reserved
2-0	WEEK	0-6h	1st digit of days in a week, Range from 0 (Sunday) to 6 (Saturday)

20.3.5.8 Alarm Second Register (ALARM_SECONDS_REG)

The ALARM_SECONDS_REG is used to program the second value for the alarm interrupt. Seconds are stored as BCD format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent.

Figure 20-65. Alarm Second Register (ALARM_SECONDS_REG)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

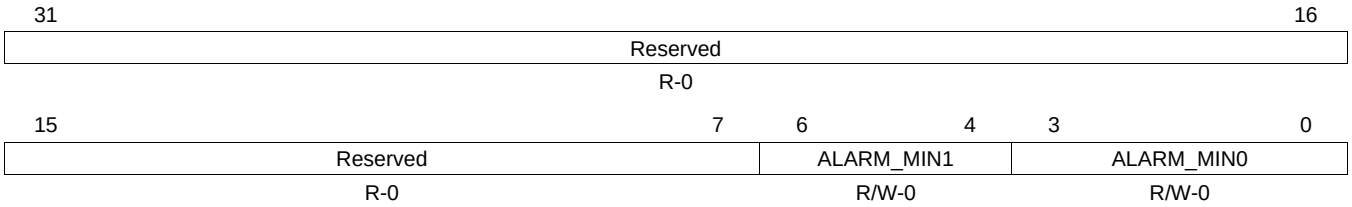
3-0	ALARMSEC0	0-9h	1st digit of seconds, Range is 0 to 9

Copyright © 2011, Texas Instruments Incorporated

20.3.5.9 Alarm Minute Register (ALARM_MINUTES_REG)

The ALARM_MINUTES_REG is used to program the minute value for the alarm interrupt. Minutes are stored as BCD format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent.

Figure 20-66. Alarm Minute Register (ALARM_MINUTES_REG)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

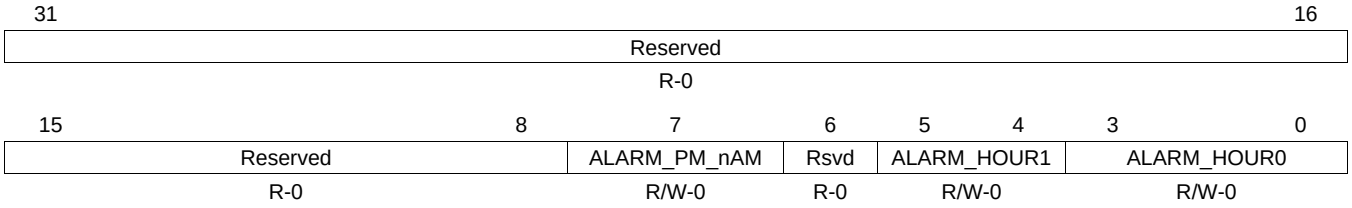
Table 20-72. Alarm Minute Register (ALARM_MINUTES_REG) Field Descriptions

Bit	Field	Value	Description
31-7	Reserved	0	Reserved
6-4	ALARM_MIN1	0-5h	2nd digit of minutes, Range is 0 to 5
3-0	ALARM_MIN0	0-9h	1st digit of minutes, Range is 0 to 9

20.3.5.10 Alarm Hour Register (ALARM_HOURS_REG)

The ALARM_HOURS_REG is used to program the hour value for the alarm interrupt. Hours are stored as BCD format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent.

Figure 20-67. Alarm Hour Register (ALARM_HOURS_REG)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 20-73. Alarm Hour Register (ALARM_HOURS_REG) Field Descriptions

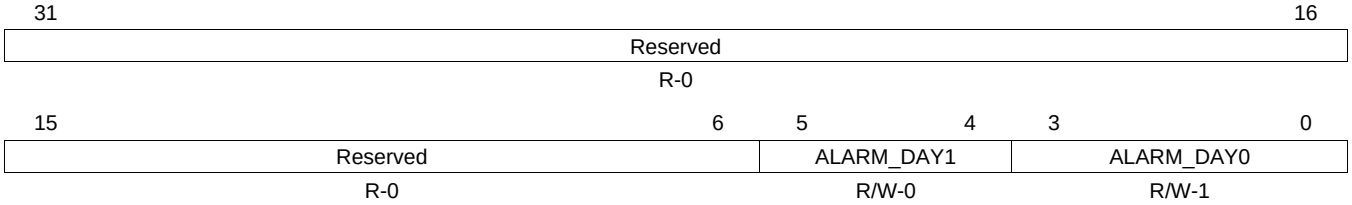
		0	AM
		1	PM
6	Reserved	0	Reserved.
5-4	ALARM_HOUR1	0-2h	2nd digit of hours, Range is 0 to 2
3-0	ALARM_HOUR0	0-9h	1st digit of hours, Range is 0 to 9

Copyright © 2011, Texas Instruments Incorporated

20.3.5.11 Alarm Day of the Month Register (ALARM_DAYS_REG)

The ALARM_DAYS_REG is used to program the day of the month value for the alarm interrupt. Days are stored as BCD format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent.

Figure 20-68. Alarm Day of the Month (ALARM_DAYS_REG)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

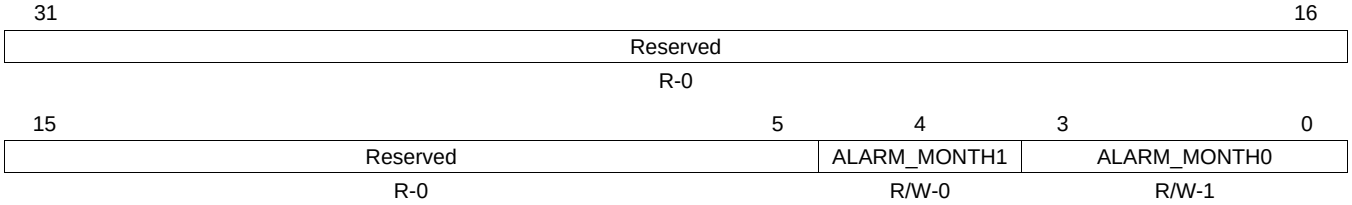
Table 20-74. Alarm Day of the Month Register (ALARM_DAYS_REG) Field Descriptions

Bit	Field	Value	Description
31-6	Reserved	0	Reserved
5-4	ALARM_DAY1	0-3h	2nd digit for days, Range from 0 to 3
3-0	ALARM_DAY0	0-9h	1st digit for days, Range from 0 to 9

20.3.5.12 Alarm Month Register (ALARM_MONTHS_REG)

The ALARM_MONTHS_REG is used to program the month in the year value for the alarm interrupt. The month is stored as BCD format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent.

Figure 20-69. Alarm Month Register (ALARM_MONTHS_REG)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 20-75. Alarm Month Register (ALARM_MONTHS_REG) Field Descriptions

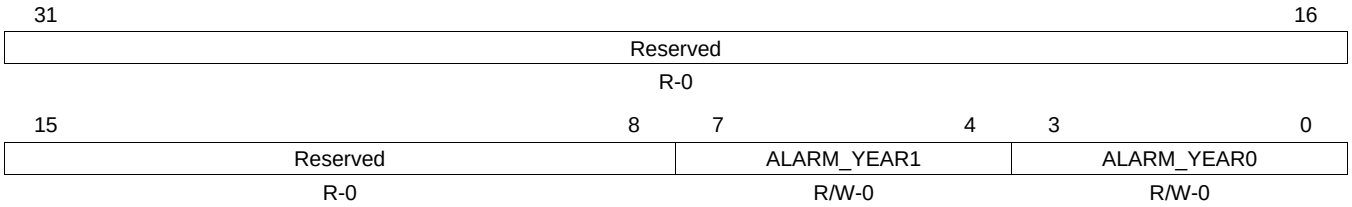
Bit	Field	Value	Description
31-5	Reserved	0	Reserved
4	ALARM_MONTH1	0-1h	2nd digit of months, Range from 0 to 1
3-0	ALARM_MONTH0	0-9h	1st digit of months, Range from 0 to 9

Copyright © 2011, Texas Instruments Incorporated

20.3.5.13 Alarm Year Register (ALARM_YEARS_REG)

The ALARM_YEARS_REG is used to program the year for the alarm interrupt. Only the last two digits are used to represent the year and is stored as BCD format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent.

Figure 20-70. Alarm Year Register (ALARM_YEARS_REG)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

3-0	ALARM_YEAR0	0-9h	1st digit of years, Range from 0 to 9

Copyright © 2011, Texas Instruments Incorporated

20.3.5.14 Control Register (CTRL_REG)

The CTRL_REG contains the controls to enable/disable RTC, set the 12/24 hour time mode, to enable the 30 second rounding feature, and to STOP/START RTC.

Figure 20-71. Control Register (CTRL_REG)

31							8
Reserved							
R-0							
7	6	5	4	3	2	1	0
Rsvd	RTC_disable	SET_32_ COUNTER	TEST_MODE	MODE_12_24	AUTO_COMP	ROUND_30S	STOP_RTC
R-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 20-77. Control Register (CTRL_REG) Field Descriptions

Bit	Field	Value	Description
31-7	Reserved	0	Reserved.
6	RTC_disable		Disable RTC module and gate 32-kHz reference clock.
		0	RTC enable
		1	RTC disable (no 32 kHz clock)
5	SET_32_COUNTER		Set the 32-kHz counter with the value stored in the compensation registers when the SET_32_COUNTER bit is set.
		0	No action.
		1	Set the 32Khz counter with compensation registers value
4	TEST_MODE		Test mode.
		0	Functional mode
		1	Test mode (Auto compensation is enabled when the 32Khz counter reaches its end)
3	MODE_12_24		Enable 12-hour mode for HOURS and ALARMHOURS registers.
		0	24-hr mode
		1	12-hour mode
2	AUTO_COMP		Enable oscillator compensation mode.
		0	No auto compensation
		1	Auto compensation enabled
1	ROUND_30S		Enable one-time rounding to nearest minute on next time register read.
		0	No update
		1	Time is rounded to the nearest minute
0	STOP_RTC		Stop the RTC 32-kHz counter.
		0	RTC is frozen
		1	RTC is running

Copyright © 2011, Texas Instruments Incorporated

NOTE:

- The SET_32_counter must only be used when the RTC is frozen.
- The RTC_DISABLE bit of the CTRL register must only be used to completely disable the RTC function. When this bit is set, the 32 kHz clock is gated, and the RTC is frozen. From this point, resetting this bit to zero can lead to unexpected behavior. This bit should only be used if the RTC function is unwanted in the application, in order to save power.
- MODE_12_24: It is possible to switch between the two modes at any time without disturbing the RTC; read or write is always performed with the current mode.
- Auto compensation is enabled by AUTO_COMP_EN bit in the RTC_CTRL register. If the COMP_REG value is positive, compensation occurs after the second change event. COMP_REG cycles are removed from the next second. If the COMP_REG value is negative, compensation occurs before the second change event. COMP_REG cycles are added to the current second. This enables it to compensate with one 32-kHz period accuracy each hour.
- ROUND_30S is a toggle bit; ARM can only write 1 and RTC clears it. If the ARM sets the ROUND_30S bit and then reads it, the ARM read 1 until the round-to-the-closet-minute is performed at the next second.
- ARM can stop the RTC by clearing STOP_RTC bit of the control register (owing to internal resynchronization, the RUN bit of the status must be checked to be ensure that the RTC is frozen), then update TC values, and re-start the RTC by resetting STOP_RTC bit.

Copyright © 2011, Texas Instruments Incorporated

20.3.5.15 Status Register (STATUS_REG)

The RTC STATUS_REG contains bits that signal the status of interrupts, events to the processor. Status for the alarm interrupt and timer events are notified by the register.

Figure 20-72. Status Register (STATUS_REG)

31	16
Reserved	
R-0	

15	8	7	6	5	4	3	2	1	0
Reserved		ALARM2	ALARM	1D_EVENT	1H_EVENT	1M_EVENT	1S_EVENT	RUN	BUSY

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 20-78. Status Register (STATUS_REG) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7	ALARM2	0	Indicates that an alarm2 interrupt has been generated. Software needs to wait 31µs before it clears this status to allow pmic_pwr_enable 1 → 0 transmission.
6	ALARM	0-1	Indicates that an alarm interrupt has been generated
5	1D_EVENT	0-1	One day has occurred
4	1H_EVENT	0-1	One hour has occurred
3	1M_EVENT	0-1	One minute has occurred
2	1S_EVENT	0-1	One second has occurred
1	RUN		RTC is frozen or is running.
		0	RTC is frozen
		1	RTC is running
0	BUSY		Status of RTC module.
		0	Updating event in more than 15 µs
		1	Updating event

Copyright © 2011, Texas Instruments Incorporated

NOTE:

- The alarm interrupt keeps its low level until the ARM writes 1 in the ALARM bit of the RTC_STATUS_REG register.
- ALARM2: This bit will indicate the status of the alarm interrupt. Writing a 1 to the bit clears the interrupt.
- ALARM: This bit will indicate the status of the alarm interrupt. Writing a 1 to the bit clears the interrupt.
- 1D_EVENT1: This bit will indicate if a day event has occurred. An interrupt will be generated to the processor based on the masking of the interrupt controller.
- 1H_EVENT1: This bit will indicate if an hour event has occurred. An interrupt will be generated to the processor based on the masking of the interrupt controller.
- 1M_EVENT1: This bit will indicate if a minute event has occurred. An interrupt will be generated to the processor based on the masking of the interrupt controller.
- 1S_EVENT1: This bit will indicate if a second event has occurred. An interrupt will be generated to the processor based on the masking of the interrupt controller.
- RUN: This bit will indicate if RTC is frozen or it is running. The RUN bit shows the real state of the RTC. Indeed, because the STOP_RTC signal is resynchronized on 32-kHz clock the action of this bit is delayed.
- BUSY: This bit will give the status of RTC module. The Time and alarm registers can be modified only when this bit is 0.
- The timer interrupt is a negative edge sensitive low-level pulse (1 OCP cycle duration).

Copyright © 2011, Texas Instruments Incorporated

20.3.5.16 Interrupt Register (INTERRUPTS_REG)

The INTERRUPTS_REG is used to enable or disable RTC from generating interrupts. The timer interrupt and alarm interrupt can be controlled using this register.

Figure 20-73. Interrupt Register (INTERRUPTS_REG)

31	16
Reserved	
R-0	

15	5	4	3	2	1	0
Reserved		IT_ALARM2	IT_ALARM	IT_TIMER	EVERY	
R-0		R/W-0	R/W-0	R/W-0	R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 20-79. Interrupt Register (INTERRUPTS_REG) Field Descriptions

Bit	Field	Value	Description
31-5	Reserved	0	Reserved
4	IT_ALARM2	0	Enable one interrupt when the alarm value is reached (TC ALARM2 registers) by the TC registers
3	IT_ALARM	0	Enable one interrupt when the alarm value is reached (TC ALARM registers) by the TC registers
2	IT_TIMER		Enable periodic interrupt.
		0	Interrupt disabled
		1	Interrupt enabled
1-0	EVERY	0-3h	Interrupt period.
		0	Every second
		1h	Every minute
		2h	Every hour
		3h	Every day

NOTE:

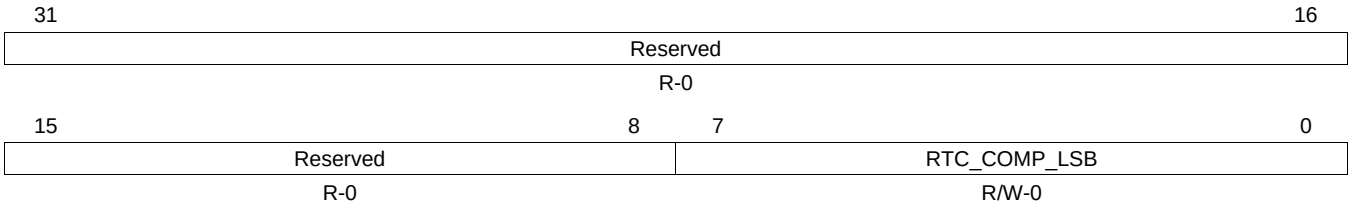
- The ARM must respect the BUSY period to prevent spurious interrupt. To set a period timer interrupt, the respective period value must be set in the EVERY field. For example, to set a periodic timer interrupt for every hour, the EVERY field has to be set to 2. Along with this the IT_TIMER bit also has to be set for the periodic interrupt to be generated.
- IT_ALARM bit has to be set to generate an alarm interrupt.

Copyright © 2011, Texas Instruments Incorporated

20.3.5.17 Compensation (LSB) Register (COMP_LSB_REG)

The COMP_LSB_REG is used to program the LSB value of the 32 kHz periods to be added to the 32 kHz counter every hour. This is used to compensate the oscillator drift. The COMP_LSB_REG works together with the compensation (MSB) register (COMP_MSB_REG). The AUTOCOMP bit in the control register (CTRL_REG) must be enabled for compensation to take place.

Figure 20-74. Compensation (LSB) Register (COMP_LSB_REG)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 20-80. Compensation (LSB) Register (COMP_LSB_REG) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7-0	RTC_COMP_LSB	0-FFh	Indicates number of 32-kHz periods to be added into the 32-kHz counter every hour

NOTE: This register must be written in two's complement. That means that to add one 32-kHz oscillator period every hour, the ARM must write FFFFh into RTC_COMP_MSB_REG and RTC_COMP_LSB_REG. To remove one 32-kHz oscillator period every hour, the ARM must write 0001h into RTC_COMP_MSB_REG and RTC_COMP_LSB_REG. The 7FFFh value is forbidden.

Copyright © 2011, Texas Instruments Incorporated

20.3.5.18 Compensation (MSB) Register (COMP_MSB_REG)

The COMP_MSB_REG is used to program the MSB value of the 32 kHz periods to be added to the 32 kHz counter every hour. This is used to compensate the oscillator drift. The COMP_MSB_REG works together with the compensation (LSB) register (COMP_LSB_REG) to set the hourly oscillator compensation value. The AUTOCOMP bit in the control register (CTRL_REG) must be enabled for compensation to take place.

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 20-82. Oscillator Register (OSC_REG) Field Descriptions

Bit	Field	Value	Description
31-7	Reserved	0	Reserved
6	32KCLK_EN	0	32-kHz clock enable post clock mux of rtc_32k_clk_rtc_32k_aux_clk and rtc_32k_clk_rtc_32k_clk
5	Reserved	0	Reserved
4	OSC32K_GZ		Disable the oscillator and apply high impedance to the output
		0	Enable
		1	Disabled and high impedance
3	32KCLK_SEL		32-kHz clock source select
		0	Selects internal clock source, namely rtc_32k_clk_rtc_32k_aux_clk
		1	Selects external clock source, namely rtc_32k_clk_rtc_32k_clk that is from the 32-kHz oscillator
2	RES_SELECT		External feedback resistor
		0	Internal
		1	External
1	SW2	0	Inverter size adjustment
0	SW1	0	Inverter size adjustment

NOTE: SW_RESET bit is set to 1 to reset the RTC module. This bit is self-clearing, and is always read as 0. CPU must care of interrupt handling before RTC is reset. After setting the SW_RESET bit, you must not access any of the RTC registers for three 32-kHz clock cycles (roughly 2200 OCP cycles).

20.3.5.20 Scratch Registers (SCRATCHx_REG)

The SCRATCH_REG is used to hold some required values for the RTC register.

20.3.5.21 Kick Registers (KICK0R, KICK1R)

The kick registers (KICKnR) are used to enable and disable write protection on the RTC registers. Out of reset, the RTC registers are write-protected. To disable write protection, correct keys must be written to the KICKnR registers.

Kick0 Register (KICK0R)

The Kick0 register allows writing to unlock the kick0 data. To disable RTC register write protection, the value of 83E7 0B13h must be written to KICK0R, followed by the value of 95A4 F1E0h written to KICK1R. RTC register write protection is enabled when any value is written to KICK0R.

20.3.5.32 RTC Debounce Register (RTC_DEBOUNCE)

The debounce timer uses the 32768-Hz clock. It allows choosing the timing or the accuracy of “debouncing”. A register receives a bit from the reference pin. You will choose the timing if you use the “debouncing” like a timer, or you will choose the accuracy if you use the debouncing like a real debouncing. The debouncing will be finished when the reference pin will stay the same value (defined in DEBOUNCE_REG) for a defined time.

20.4 WATCHDOG

20.4.1 Introduction

The watchdog timer is an upward counter capable of generating a pulse on the reset pin and an interrupt to the device system modules following an overflow condition. The watchdog timer serves resets to the PRCM module and serves watchdog interrupts to the host ARM and DSP. The reset of the PRCM module causes warm reset of the device.

The watchdog timer can be accessed, loaded, and cleared by registers through the L4 interface. The watchdog timer have the 32-kHz clock for their timer clock input.

The watchdog timer connects to a single target agent port on the L4 interconnect. The default state of the watchdog timer is enabled and not running.

20.4.1.1 Features

The main features of the watchdog timer controllers are:

- L4 slave interface support:
  - 32-bit data bus width
  - 32-/16-bit access supported
  - 8-bit access not supported
  - 11-bit address bus width
  - Burst mode not supported
  - Write nonposted transaction mode only
- Free-running 32-bit upward counter
- Programmable divider clock source (2n where n = 0-7)
- On-the-fly read/write register (while counting)
- Subset programming model of the GP timer
- The watchdog timers are reset either on power-on or after a warm reset before they start counting.
- Reset or interrupt actions when a timer overflow condition occurs
- The watchdog timer generates a reset or an interrupt in its hardware integration.

20.4.1.2 Unsupported Featres

There are no unsupported WD Timer features in this device.

Copyright © 2011, Texas Instruments Incorporated

20.4.2 Integration

20.4.2.1 Public WD Timer Connectivity Attributes

The general connectivity for the WD Timer module in this device is shown in Table 20-97.

Table 20-97. Public WD Timer Module Connectivity Attributes

Attributes	Type
Power Domain	Wakeup Domain
Clock Domain	PD_WKUP_L4_WKUP_GCLK (OCP) PD_WKUP_WDT1_GCLK (Func)
Reset Signals	WKUP_DOM_RST_N
Idle/Wakeup Signals	Smart Idle / Slave Wakeup
Interrupt Requests	1 Interrupt to MPU Subsystem (WDT1INT) and WakeM3
DMA Requests	None
Physical Address	L4 Wakeup slave port

20.4.2.2 Public WD Timer Clock and Reset Management

The Watchdog Timer functional clock (pi_sys_clk input) is sourced from either the on-chip ~32678 Hz oscillator (CLK_RC32K) or the PER PLL generated 32.768 KHz clock (CLK_32KHZ) as selected using CLKSEL_WDT1_CLK[CLKSEL] in the PRCM.

Table 20-98. Public WD Timer Clock Signals

Clock Signal	Max Freq	Reference / Source	Comments
PI_OCP_CLK Interface clock	100 MHz	CORE_CLKOUTM4 / 2	pd_wkup_l4_wkup_gclk from PRCM
PI_SYS_CLK Functional clock	32768 Hz	CLK_RC32K or CLK_32KHZ (PER_CLKOUTM2 / 5859.375)	pd_wkup_wdt1_gclk from PRCM

Copyright © 2011, Texas Instruments Incorporated

20.4.3 Functional Description

20.4.3.1 Power Management

There are two clock domains in the watchdog timers:

- Functional clock domain: WDTi_FCLK is a 32 kHz watchdog timer functional clock. It is used to clock the watchdog timer internal logic.
- Interface clock domain: WDTi_ICLK is a 125 MHz watchdog timer interface clock. It is used to synchronize the watchdog timer L4 port to the L4 interconnect. All accesses from the interconnect are synchronous to WDTi_ICLK.

In this device, the clocks to the watchdog timers are always On. The clocks cannot be turned off, if the watchdog timers is not being used.

20.4.3.2 Interrupts

Table 20-99 list the event flags, and their masks, that cause module interrupts.

Table 20-99. Watchdog Timer Events

Event Flag	Event Mask	Mapping	Comments
WDT_WIRQSTAT[0] EVENT_OVF	WDT_WIRQENSET/WDT_WIRQENCLR[0] OVF_IT_ENA	WDTINT	Watchdog timer overflow
WDT_WIRQSTAT[1] EVENT_DLY	WDT_WIRQENSET/WDT_WIRQENCLR[1] DLY_IT_ENA	WDTINT	Watchdog delay value reached

20.4.3.3 General Watchdog Timer Operation

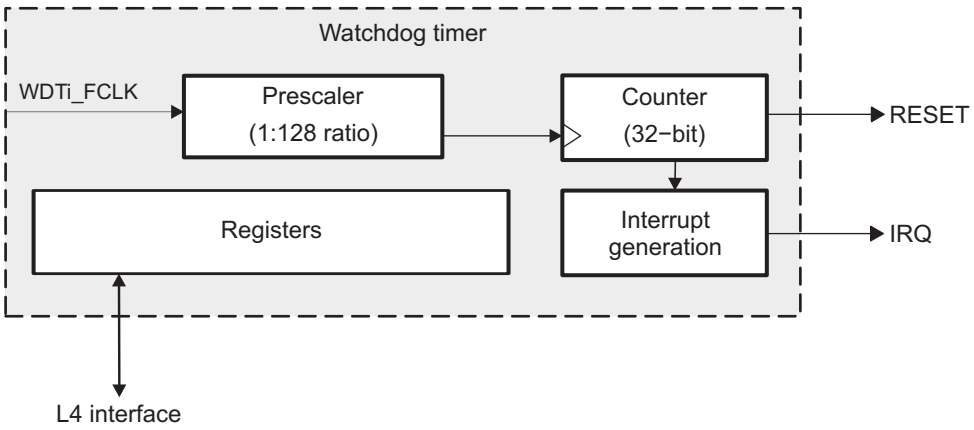
The watchdog timers are based on an upward 32-bit counter coupled with a prescaler. The counter overflow is signaled through two independent signals: a simple reset signal and an interrupt signal, both active low. Figure 20-91 is a functional block diagram of the watchdog timer.

The interrupt generation mechanism is controlled through the WDT_WIRQENSET/WDT_WIRQENCLR and WDT_WIRQSTAT registers.

The prescaler ratio can be set from 1 to 128 by accessing the WDT_WCLR[4:2] PTV bit field and the WDT_WCLR[5] PRE bit of the watchdog control register (WDT_WCLR).

The current timer value can be accessed on-the-fly by reading the watchdog timer counter register (WDT_WCRR), modified by accessing the watchdog timer load register (WDT_WLDR) (no on-the-fly update), or reloaded by following a specific reload sequence on the watchdog timer trigger register (WDT_WTGR). A start/stop sequence applied to the watchdog timer start/stop register (WDT_WSPR) can start and stop the watchdog timers.

Figure 20-91. 32-Bit Watchdog Timer Functional Block Diagram



Copyright © 2011, Texas Instruments Incorporated

20.4.3.4 Reset Context

The watchdog timers are enabled after reset. Table 20-100 lists the default reset values of the two watchdog timer load registers (the WDT_WLDR) and prescaler ratios (the WDT_WCLR[4:2] PTV bit field). To get these values, software must read the corresponding WDT_WCLR[4:2] PTV bit field and the 32-bit register to retrieve the static configuration of the module.

Table 20-100. Count and Prescaler Default Reset Values

Timer	WDT_WLDR Reset Value	PTV Reset Value
WDT	FFFF FFBEh	0

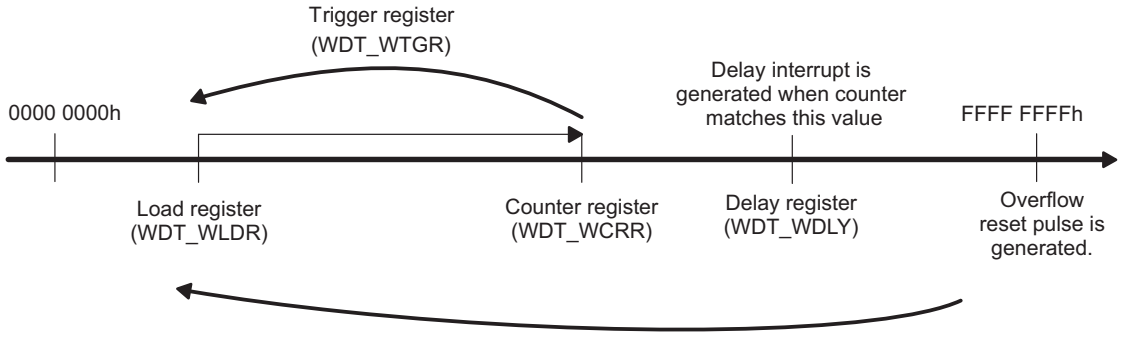
20.4.3.5 Overflow/Reset Generation

When the watchdog timer counter register (WDT_WCRR) overflows, an active-low reset pulse is generated to the PRCM module. This RESET pulse causes the PRCM module to generate global WARM reset of the device. It is also driven out of the device through the WD_OUT pin. This pulse is one prescaled timer clock cycle wide and occurs at the same time as the timer counter overflow.

After reset generation, the counter is automatically reloaded with the value stored in the watchdog load register (WDT_WLDR) and the prescaler is reset (the prescaler ratio remains unchanged). When the reset pulse output is generated, the timer counter begins incrementing again.

Figure 20-92 shows a general functional view of the watchdog timers.

Figure 20-92. Watchdog Timers General Functional View



20.4.3.6 Prescaler Value/Timer Reset Frequency

Each watchdog timer is composed of a prescaler stage and a timer counter.

The timer rate is defined by the following values:

- Value of the prescaler fields (the WDT_WCLR[5] PRE bit and the WDT_WCLR[4:2] PTV bit field)
- Value loaded into the timer load register (WDT_WLDR)

The prescaler stage is clocked with the timer clock and acts as a clock divider for the timer counter stage. The ratio is managed by accessing the ratio definition field (the WDT_WCLR[4:2] PTV bit field) and is enabled with the WDT_WCLR[5] PRE bit.

Table 20-101 lists the prescaler clock ratio values.

Copyright © 2011, Texas Instruments Incorporated

Table 20-101. Prescaler Clock Ratio Values

WDT_WCLR[5] PRE	WDT_WCLR[4:2] PTV	Clock Divider (PS)
0	X	1
1	0	1
1	1	2
1	2	4
1	3	8
1	4	16
1	5	32
1	6	64
1	7	128

Thus the watchdog timer overflow rate is expressed as:

OVF_Rate = (FFFF FFFFh – WDT_WLDR + 1) × (wd-functional clock period) × PS

where wd-functional clock period = 1/(wd-functional clock frequency) and PS = $2^{(PTV)}$

CAUTION

Internal resynchronization causes some latency in any software write to WDT_WSPR before WDT_WSPR is updated with the programmed value:

1.5 × functional clock cycles ≤ write_WDT_WSPR_latency ≤ 2.5 × functional clock cycles

Remember to consider this latency whenever the watchdog timer must be started or stopped.

For example, for a timer clock input of 32 kHz with a prescaler ratio value of 1 (clock divided by 2) and WDT_WCLR[5] PRE = 1 (clock divider enabled), the reset period is as listed in Table 20-102.

Table 20-102. Reset Period Examples

WDT_WLDR Value	Reset Period
0000 0000h	74 h 56 min
FFFF 0000h	4 s
FFFF FFF0h	1 ms
FFFF FFFFh	62.5 us

CAUTION

- Ensure that the reloaded value allows the correct operation of the application. When a watchdog timer is enabled, software must periodically trigger a reload before the counter overflows. Hence, the value of the WDT_WLDR[31:0] bit field must be chosen according to the ongoing activity preceding the watchdog reload.
- Due to design reasons, WDT_WLDR[31:0] = FFFF FFFFh is a special case, although such a value of WDT_WLDR is meaningless. When WDT_WLDR is programmed with the overflow value, a triggering event generates a reset/interrupt one functional clock cycle later, even if the watchdog timer is stopped.

Copyright © 2011, Texas Instruments Incorporated

Table 20-103 lists the default reset periods for the watchdog timers.

Table 20-103. Default Watchdog Timer Reset Periods

Watchdog Timers	Clock Source	Default Reset Period
WDT	32 kHz	2 s

20.4.3.7 Triggering a Timer Reload

To reload the timer counter and reset the prescaler before reaching overflow, a reload command is executed by accessing the watchdog timer trigger register (WDT_WTGR) using a specific reload sequence.

The specific reload sequence is performed whenever the written value on the WDT_WTGR register differs from its previous value. In this case, reload is executed in the same way as an overflow autoreload, but without the generation of a reset pulse.

The timer counter is loaded with the value of the watchdog timer load register (the WDT_WLDR[31:0] TIMER_LOAD bit field), and the prescaler is reset.

20.4.3.8 Start/Stop Sequence for Watchdog Timers (Using the WDT_WSPR Register)

To start and stop a watchdog timer, access must be made through the start/stop register (WDT_WSPR) using a specific sequence.

To disable the timer, follow this sequence:

1. Write XXXX AAAAh in WDT_WSPR.
2. Write XXXX 5555h in WDT_WSPR.

To enable the timer, follow this sequence:

1. Write XXXX BBBBh in WDT_WSPR.
2. Write XXXX 4444h in WDT_WSPR.

All other write sequences on the WDT_WSPR register have no effect on the start/stop feature of the module.

20.4.3.9 Modifying Timer Count/Load Values and Prescaler Setting

To modify the timer counter value (the WDT_WCRR register), prescaler ratio (the WDT_WCLR[4:2] PTV bit field), delay configuration value (the WDT_WDLY[31:0] DLY_VALUE bit field), or the load value (the WDT_WLDR[31:0] TIMER_LOAD bit field), the watchdog timer must be disabled by using the start/stop sequence (the WDT_WSPR register).

After a write access, the load register value and prescaler ratio registers are updated immediately, but new values are considered only after the next consecutive counter overflow or after a new trigger command (the WDT_WTGR register).

20.4.3.10 Watchdog Counter Register Access Restriction (WDT_WCRR Register)

A 32-bit shadow register is implemented to read a coherent value of the WDT_WCRR register because the WDT_WCRR register is directly related to the timer counter value and is updated on the timer clock (WDT_FCLK). The shadow register is updated by a 16-bit LSB read command.

NOTE: Although the L4 clock (WDT_ICLK) is completely asynchronous with the timer clock (WDT_FCLK), some synchronization is performed to ensure that the value of the WDT_WCRR register is not read while it is being incremented.

When 32-bit read access is performed, the shadow register is not updated. Read access is performed directly from the accessed register.

Copyright © 2011, Texas Instruments Incorporated

To ensure that a coherent value is read inside WDT_WCRR, the first read access is to the lower 16 bits (offset = 8h), followed by read access to the upper 16 bits (offset = Ah).

20.4.3.11 Watchdog Timer Interrupt Generation

When an interrupt source occurs, the interrupt status bit (the WDT_WIRQSTAT[0] EVENT_OVF or WDT_WIRQSTAT[1] EVENT_DLY bit) is set to 1. The output interrupt line (WDTi_IRQ) is asserted (active low) when status (the EVENT_xxx bit) and enable (the xxx_IT_ENA bit) flags are set to 1; the order is not relevant. Writing 1 to the enable bit (the status is already set at 1) also triggers the interrupt in the normal order (enable first, status next). The pending interrupt event is cleared when the set status bit is overwritten by a value of 1 by a write command in the WDT_WIRQSTAT register. Reading the WDT_WIRQSTAT register and writing the value back allows a fast interrupt acknowledge process.

The watchdog timer issues an overflow interrupt if this interrupt is enabled in the watchdog interrupt enable register (WDT_WIRQENSET[0] OVF_IT_ENA = 1). When the overflow occurs, the interrupt status bit (the WDT_WIRQSTAT[0] EVENT_OVF bit) is set to 1. The output interrupt line (WDT_IRQ) is asserted (active low) when status (EVENT_OVF) and enable (OVF_IT_ENA) flags are set to 1; the order is not relevant. This interrupt can be disabled by setting the WDT_WIRQENCLR[0] OVF_IT_ENA bit to 1.

The watchdog can issue the delay interrupt if this interrupt is enabled in the interrupt enable register (WDT_WIRQENSET[1] DLY_IT_ENA = 1). When the counter is running and the counter value matches the value stored in the delay configuration register (WDT_WDLY), the corresponding interrupt status bit is set in the watchdog status register (WDT_WIRQSTAT) and the output interrupt line is asserted (active low) when the flag (EVENT_DLY) and enable (DLY_IT_ENA) bits are 1 in the WDT_WIRQSTAT and WDT_WIRQENSET registers, respectively; the order (normally enable, then flag), is not relevant. This interrupt can be disabled by setting the WDT_WIRQENCLR[1] DLY_IT_ENA bit to 1.

NOTE: Writing 0 to the WDT_WIRQSTAT[0] EVENT_OVF bit or the WDT_WIRQSTAT[1] EVENT_DLY bit has no effect.

The two clock domains are resynchronized because the interrupt event is generated on the functional clock domain (WDTi_FCLK) during the updating of the interrupt status register (WDT_WIRQSTAT).

The WDT_WDLY register is used to specify the value of the delay configuration register. The delay time to interrupt is the difference between the reload value stored in the counter load register (WDT_WLDR) and the programmed value in this register (WDT_WDLY).

Use the following formula to estimate the delay time:

Delay time period = (WDT_WDLY – WDT_WLDR + 1) × *Timer clock period* × *Clock divider*

Where:

- Timer clock period = 1/(Timer clock frequency)
- Clock divider = 2PTV

If the counter value (WDT_WCRR) reaches the programmed value (WDT_WDLY), the status bit (EVENT_DLY) gets set in the interrupt status register (WDT_WIRQSTAT), and an interrupt occurs if the corresponding enable bit is set in the interrupt enable register (WDT_WIRQENSET).

CAUTION

If the reload event occurs (after a triggering sequence or after a reset sequence) before reaching the programmed value (WDT_WDLY[31:0] WDLY_VALUE), no interrupt is generated.

Also, no interrupt is generated if the value programmed in the delay configuration register (WDT_WDLY) is less than the value stored in the counter load register (WDT_WLDR).

Copyright © 2011, Texas Instruments Incorporated

20.4.3.12 Watchdog Timers Under Emulation

During emulation mode, the watchdog timer can/cannot continue running, according to the value of the WDT_WDSC[5] EMUFREE bit of the system configuration register (WDT_WDSC).

- When EMUFREE is 1, watchdog timer execution is not stopped and a reset pulse is still generated when overflow is reached.
- When EMUFREE is 0, the counters (prescaler/timer) are frozen and incrementation restarts after exiting from emulation mode.

20.4.3.13 Accessing Watchdog Timer Registers

Posted/nonposted selection applies only to functional registers that require synchronization on/from the timer functional clock domain (WDTi_FCLK). For write/read operation, the following registers are affected:

- WDT_WCLR
- WDT_WCRR
- WDT_WLDR
- WDT_WTGR
- WDT_WDLY
- WDT_WSPR

The timer interface clock domain synchronous registers are not affected by the posted/nonposted selection; the write/read operation is effective and acknowledged (command accepted) after one WDT_ICLK cycle from the command assertion. The timer interface clock domain synchronous registers are:

- WDT_WIDR
- WDT_WDSC
- WDT_WDST
- WDT_WIRQSTATRAW
- WDT_WIRQSTAT
- WDT_WIRQENSET
- WDT_WIRQENCLR
- WDT_WWPS

NOTE: Accesses to WDT2 and WDT3 are posted.

20.4.3.14 Low-Level Programming Model

This section covers the low-level hardware programming sequences for configuration and use of the module.

20.4.3.14.1 Global Initialization

20.4.3.14.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the watchdog timer is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the watchdog timer (see Table 20-104).

Table 20-104. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	The module interface and functional clocks must be enabled.
Control module	Module-specific pad multiplexing must be set in the control module.
MPU INTC	The MPU INTC configuration must be performed to enable the interrupts from the watchdog timer.

20.4.3.14.1.2 Main Sequence – Watchdog Timer Module Global Initialization

Table 20-105 lists the steps for initializing the watchdog timer module when the module is to be used for the first time.

Table 20-105. Watchdog Timer Module Global Initialization

Step	Register/Bit Field/Programming Model	Value
Execute software reset.	WDT_WDSC[1] SOFTRESET	1
Wait until reset release?	WDT_WDSC[1] SOFTRESET	0
Enable delay interrupt.	WDT_WIRQENSET[1] ENABLE_DLY	1
Enable overflow interrupt.	WDT_WIRQENSET[0] ENABLE_OVF	1

20.4.3.14.2 Operational Mode Configuration

20.4.3.14.2.1 Main Sequence – Watchdog Timer Basic Configuration

Table 20-106 lists the steps for the basic configuration of the watchdog timer.

Table 20-106. Watchdog Timer Basic Configuration

Step	Register/Bit Field/Programming Model	Value
Disable the watchdog timer.	See Section 20.4.3.14.2.2.	
Set prescaler value.	WDT_WCLR[4:2] PTV	xxx
Enable prescaler.	WDT_WCLR[5] PRE	1
Load delay configuration value.	WDT_WDLY	xxx
Load timer counter value.	WDT_WCRR	xxx
Enable the watchdog timer.	See Section 20.4.3.14.2.3.

20.4.5 Watchdog Timer Registers

The watchdog timer registers are listed in Table 20-109.

CAUTION

The watchdog timers registers are limited to 32-bit and 16-bit data accesses; 8-bit access is not allowed and can corrupt register content.

NOTE:

- The WDT_WISR and WDT_WIRQSTATRAW registers have the same functionality. The WDT_WISR register is used for software backward compatibility.
- The WDT_WIER and WDT_WIRQENSET/WDT_WIRQENCLR registers have the same functionality. The WDT_WIER register is used for software backward compatibility.
- The WDT_WIRQSTATRAW and WDT_WIRQSTAT registers give the same information when read. The WDT_WIRQSTATRAW register is used for debug.

20.4.5.5 WDT_WIER Register

The WDT_WIERs register controls (enable/disable) the interrupt events. It is shown and described in the figure and table below.

Figure 20-97. WDT_WIER Register

31	2	1	0
Reserved		DLY_IT_ENA	OVF_IT_ENA
R-0		R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 20-114. WDT_WIER Register Field Descriptions

Bits	Field	Description
31-2	Reserved	Reads return 0.
1	DLY_IT_ENA	Delay interrupt enable/disable 0: Disable delay interrupt. 1: Enable delay interrupt.
0	OVF_IT_ENA	Overflow interrupt enable/disable 0: Disable overflow interrupt. 1: Enable overflow interrupt.

20.4.5.6 WDT_WCLR Register

The WDT_WCLR register controls the prescaler stage of the counter. It is shown and descirbed in the figure and table below.

Figure 20-98. WDT_WCLR Register

31	6	5	4	2	0
Reserved		PRE	PTV		Rsvd
R-0		R/W-1	R/W-0		R-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 20-115. WDT_WCLR Register Field Descriptions

Bits	Field	Description
31-6	Reserved	Reads return 0.
5	PRE	Prescaler enable/disable configuration 0: Prescaler disabled 1: Prescaler enabled
4-2	PTV	Prescaler value The timer counter is prescaled with the value: 2**PTV. Example: PTV = 3 -> counter increases value if started after 8 functional clock periods. On reset, it is loaded from PI_PTV_RESET_VALUE input port.
1-0	Reserved	Write 0s for future compatibility. Reads return 0.

21.1 Introduction

The multi-master I2C peripheral provides an interface between a CPU and any I2C-bus-compatible device that connects via the I2C serial bus. External components attached to the I2C bus can serially transmit/receive up to 8-bit data to/from the CPU device through the two-wire I2C interface.

The I2C bus is a multi-master bus. The I2C controller does support the multi-master mode that allows more than one device capable of controlling the bus to be connected to it. Each I2C device is recognized by a unique address and can operate as either transmitter or receiver, according to the function of the device. In addition to being a transmitter or receiver, a device connected to the I2C bus can also be considered as master or slave when performing data transfers. Note that a master device is the device which initiates a data transfer on the bus and generates the clock signals to permit that transfer. During this transfer, any device addressed by this master is considered a slave.

21.1.1 I2C Features

The general features of the I2C controller are:

- Compliant with Philips I2C specification version 2.1
- Supports OmniVision Serial Camera Control Bus Protocol (SCCB)
- Supports standard mode (up to 100K bits/s), fast mode (up to 400K bits/s) and high speed mode (up to 3.4Mb/s).
- Multimaster transmitter/slave receiver mode
- Multimaster receiver/slave transmitter mode
- Combined master transmit/receive and receive/transmit modes
- 7-bit and 10-bit device addressing modes
- Built-in FIFO for buffered read or write
  - I2C0: 32 bytes
  - I2C1: 32 bytes
- Programmable clock generation
- Two DMA channels, one interrupt line

21.1.2 Unsupported I2C Features

The I2C module features not supported in this device are shown in Table 21-1.

Table 21-1. Unsupported I2C Features

Feature	Reason
SCCB Protocol	SCCB signal not pinned out
High Speed (3.4 MBPS) operation	Not required

21.2 Integration

This device includes three instantiations of the I2C module. This peripheral implements the multi-master I2C bus which allows serial transfer of 8-bit data to/from other I2C master/slave devices through a two-wire interface. There are three I2C modules instantiations called I2C0, I2C1, and I2C2. The I2C0 module is located in the Wake-up power domain. Figure 21-1 and Figure 21-2 show examples of a system with multiple I2C-compatible devices.

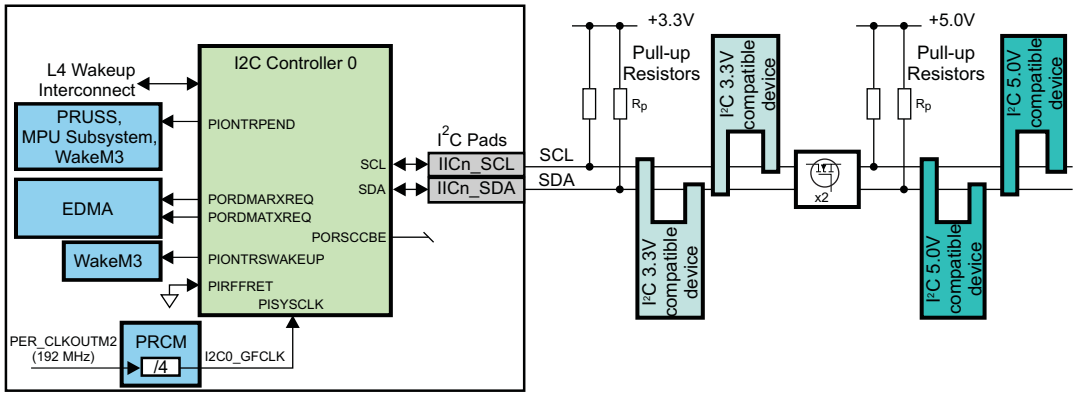

Figure 21-1. I2C0 Integration and Bus Application

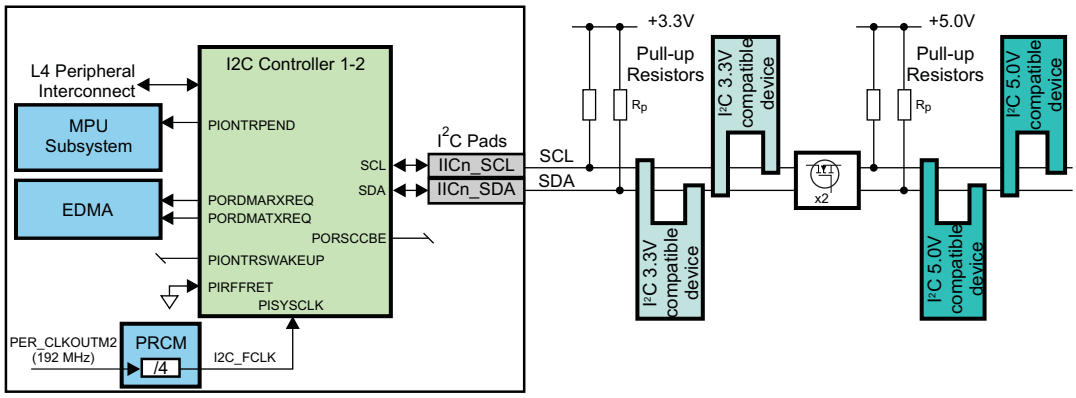

Figure 21-2. I2C(1–2) Integration and Bus Application

21.2.1 I2C Connectivity Attributes

The general connectivity attributes for the I2C module are shown in Table 21-2 and Table 21-3.

Table 21-2. I2C0 Connectivity Attributes

Attributes	Type
Power Domain	Wakeup Domain
Clock Domain	PD_WKUP_L4_WKUP_GCLK (Interface/OCP) PD_WKUP_I2C0_GFCLK (Func)
Reset Signals	WKUP_DOM_RST_N
Idle/Wakeup Signals	Smart Idle / Wakeup
Interrupt Requests	1 interrupt to MPU Subsystem (I2C0INT), PRUSS, and WakeM3
DMA Requests	2 DMA requests to EDMA (I2CTXEVT0, I2CRXEVT0)
Physical Address	L4 Wakeup slave port

Table 21-3. I2C(1–2) Connectivity Attributes

Attributes	Type
Power Domain	Peripheral Domain
Clock Domain	PD_PER_L4LS_GCLK (Interface/OCP) PD_PER_I2C_FCLK (Func)
Reset Signals	PER_DOM_RST_N
Idle/Wakeup Signals	Smart Idle
Interrupt Requests	1 interrupt per instance to MPU Subsystem (I2C1INT, I2C2INT)
DMA Requests	2 DMA requests per instance to EDMA (I2CTXEVTx, I2CRXEVTx)
Physical Address	L4 Peripheral slave port

21.2.2 I2C Clock and Reset Management

The I2C controllers have separate bus interface and functional clocks. During power-down mode, the I2C*x*_SCL and I2C*x*_SDA are configured as inputs.

Table 21-4. I2C Clock Signals

Clock Signal	Max Freq	Reference / Source	Comments
I2C0 Clock Signals			
PIOCPCLK Interface clock	100 MHz	CORE_CLKOUTM4 / 2	pd_wkup_l4_wkup_gclk From PRCM
PISYSCLK Functional clock	48 MHz	PER_CLKOUTM2 / 4	pd_wkup_i2c0_gfclk From PRCM
I2C(1-2) Clock Signals			
PIOCPCLK Interface clock	100 MHz	CORE_CLKOUTM4 / 2	pd_per_l4ls_gclk From PRCM
PISYSCLK Functional clock	48 MHz	PER_CLKOUTM2 / 4	pd_per_ic2_fclk From PRCM

21.2.3 I2C Pin List

The external signals (I2C*x*_SDA, I2C*x*_SCL) on the device use standard LVCMOS I/Os and may not meet full compliance with the I2C specifications for Fast-mode devices for slope control and input filtering (spike suppression) to improve the EMC behavior.

Table 21-5. I2C Pin List

Pin	Type	Description
I2C*x*_SCL	I/OD	I2C serial clock (open drain)
I2C*x*_SDA	I/OD	I2C serial data (open drain)

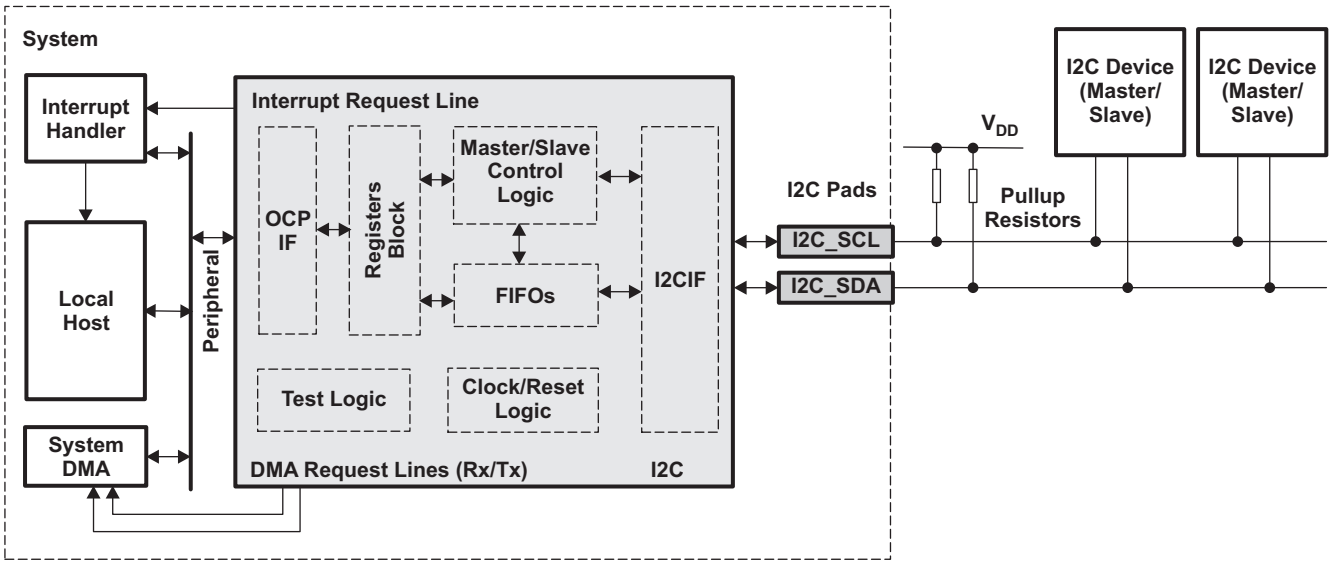
21.3 Functional Description

21.3.1 Functional Block Diagram

Figure 21-3 shows an example of a system with multiple I2C compatible devices in which the I2C serial ports are all connected together for a two-way transfer from one device to other devices.

Figure 21-3. I2C Functional Block Diagram



The I2C peripheral consists of the following primary blocks:

- A serial interface: one data pin (I2C_SDA) and one clock pin (I2C_SCL).
- Data registers to temporarily hold receive data and transmit data traveling between the I2C_SDA pin and the CPU or the DMA controller.
- Control and status registers
- A peripheral data bus interface to enable the CPU and the DMA controller to access the I2C peripheral registers.
- A clock synchronizer to synchronize the I2C input clock (from the processor clock generator) and the clock on the I2C_SCL pin, and to synchronize data transfers with masters of different clock speeds.
- A prescaler to divide down the input clock that is driven to the I2C peripheral
- A noise filter on each of the two pins, I2C_SDA and I2C_SCL
- An arbitrator to handle arbitration between the I2C peripheral (when it is a master) and another master
- Interrupt generation logic, so that an interrupt can be sent to the CPU
- DMA event generation logic to send an interrupt to the CPU upon reception and data transmission of data.

21.3.2 I2C Master/Slave Contoller Signals

Data is communicated to devices interfacing with the I2C via the serial data line (SDA) and the serial clock line (SCL). These two wires can carry information between a device and others connected to the I2C bus. Both SDA and SCL are bi-directional pins. They must be connected to a positive supply voltage via a pull-up resistor. When the bus is free, both pins are high. The driver of these two pins has an open drain to perform the required wired-AND function.

An example of multiple I2C modules that are connected for a two-way transfer from one device to other devices is shown in Figure 21-4.

Copyright © 2011, Texas Instruments Incorporated

Figure 21-4. Multiple I2C Modules Connected

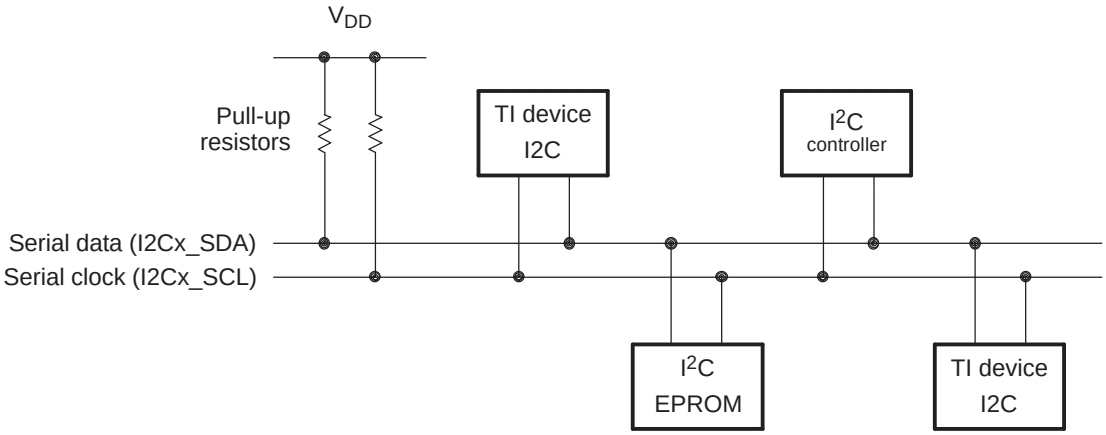


Table 21-6. Signal Pads

	I2C Mode	
Name	Default Operating Mode	Description
I2C_SCL	In/ Out	I2C serial CLK line Open-drain output buffer. Requires external pull-up resistor (Rp).
I2C_SDA	In/ Out	I2C serial data line Open-drain output buffer. Requires external pull-up resistor (Rp).

21.3.3 I2C Reset

The I2C module can be reset in the following three ways:

- A system reset (PIRSTNA = 0). A device reset causes the system reset. All registers are reset to power up reset values.
- A software reset by setting the SRST bit in the I2C_SYSC register. This bit has exactly the same action on the module logic as the system bus reset. All registers are reset to power up reset values.
- The I2C_EN bit in the I2C_CON register can be used to hold the I2C module in reset. When the system bus reset is removed (PIRSTNA = 1), I2C_EN = 0 keeps the functional part of I2C module in reset state and all configuration registers can be accessed. I2C_EN = 0 does not reset the registers to power up reset values.

Table 21-7. Reset State of I2C Signals

			I2C Reset
Pin	I/O/Z [1]	System Reset	(I2C_EN = 0)
SDA	I/O/Z	High impedance	High impedance
SCL	I/O/Z	High impedance	High impedance

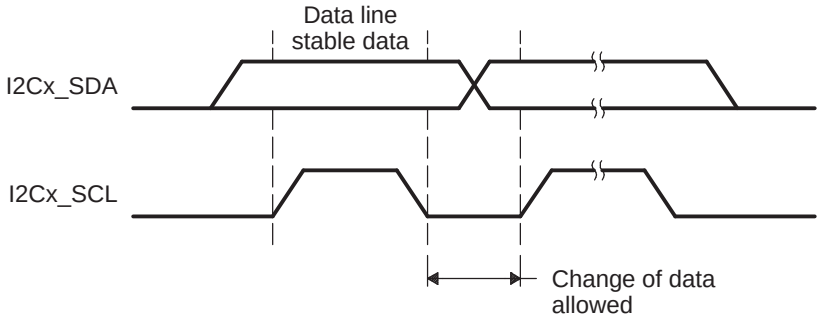
(1) I = Input, O = Outpu, Z = High impedance

21.3.4 Data Validity

The data on the SDA line must be stable during the high period of the clock. The high and low states of the data line can only change when the clock signal on the SCL line is LOW.

Copyright © 2011, Texas Instruments Incorporated

Figure 21-5. Bit Transfer on the I2C Bus



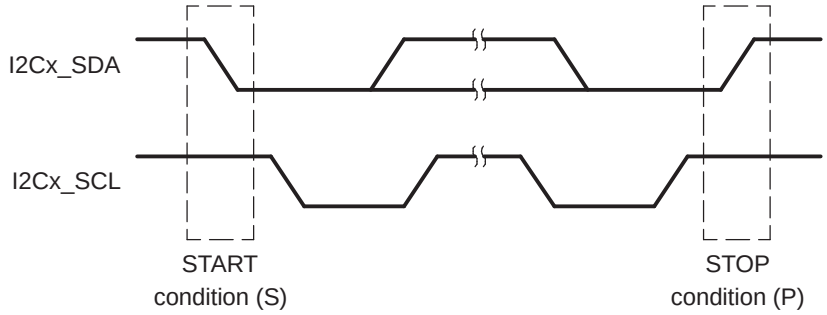
Copyright © 2011, Texas Instruments Incorporated

21.3.5 START & STOP Conditions

The I2C module generates START and STOP conditions when it is configured as a master.

- START condition is a high-to-low transition on the SDA line while SCL is high.
- STOP condition is a low-to-high transition on the SDA line while SCL is high.
- The bus is considered to be busy after the START condition (BB = 1) and free after the STOP condition (BB = 0).

Figure 21-6. Start and Stop Condition Events

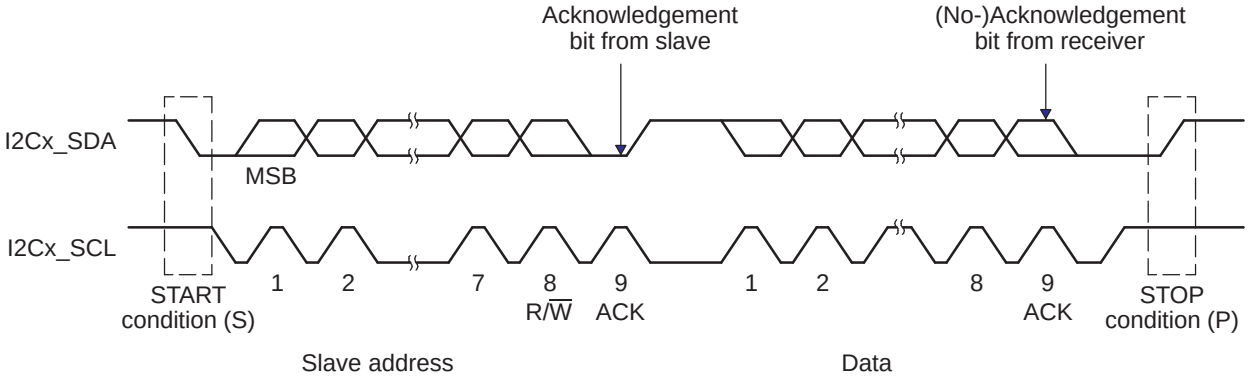


21.3.6 I2C Operation

21.3.6.1 Serial Data Formats

The I2C controller operates in 8-bit word data format (byte write access supported for the last access). Each byte put on the SDA line is 8 bits long. The number of bytes that can be transmitted or received is restricted by the value programmed in the DCOUNT register. The data is transferred with the most significant bit (MSB) first. Each byte is followed by an acknowledge bit from the I2C module if it is in receiver mode.

Figure 21-7. I2C Data Transfer



The I2C module supports two data formats, as shown in Figure 21-8:

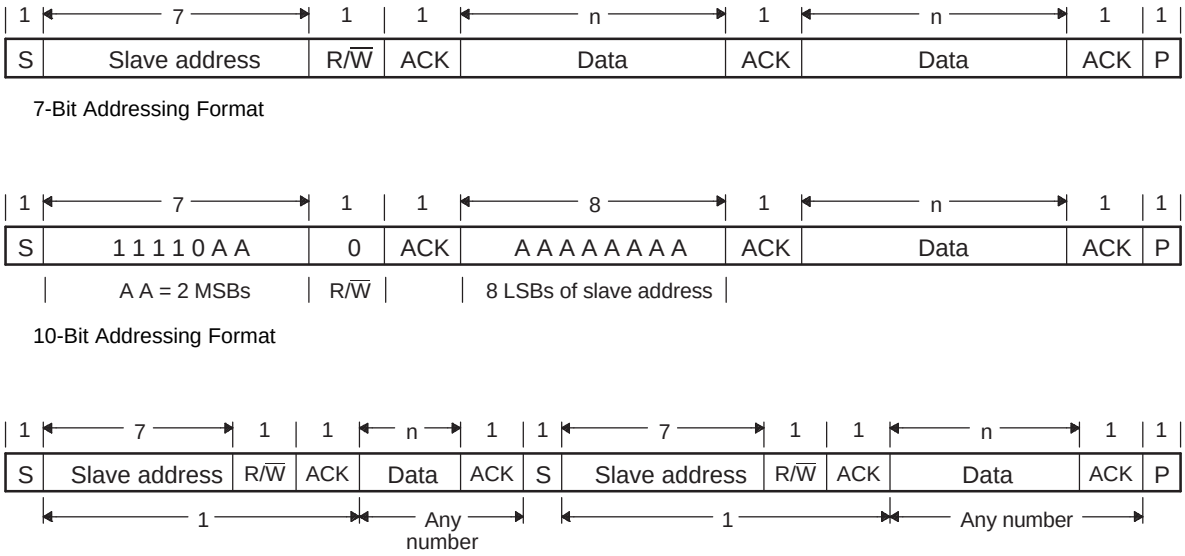
- 7-bit/10-bit addressing format
- 7-bit/10-bit addressing format with repeated start condition

The first byte after a start condition (S) always consists of 8 bits. In the acknowledge mode, an extra bit dedicated for acknowledgment is inserted after each byte. In the addressing formats with 7-bit addresses, the first byte is composed of 7 MSB slave address bits and 1 LSB R/nW bit. In the addressing formats with 10-bit addresses, the first byte is composed of 7 MSB slave address bits, such as 11110XX, where XX is the two MSB of the 10-bit addresses, and 1 LSB R/nW bit, which is 0 in this case.

Copyright © 2011, Texas Instruments Incorporated

The least significant R/nW of the address byte indicates the direction of transmission of the following data bytes. If R/nW is 0, the master writes data into the selected slave; if it is 1, the master reads data out of the slave.

Figure 21-8. I2C Data Transfer Formats



21.3.6.2 Master Transmitter

In this mode, data assembled in one of the previously described data formats is shifted out on the serial data line SDA in synch with the self-generated clock pulses on the serial clock line SCL. The clock pulses are inhibited and SCL held low when the intervention of the processor is required (XUDF) after a byte has been transmitted.

21.3.6.3 Master Receiver

This mode can only be entered from the master transmitter mode. With either of the address formats (Figure 21-8 (a), (b), and (c)), the master receiver is entered after the slave address byte and bit R/W_ has been transmitted, if R/W_ is high. Serial data bits received on bus line SDA are shifted in synch with the self-generated clock pulses on SCL. The clock pulses are inhibited and SCL held low when the intervention of the processor is required (ROVR) after a byte has been transmitted. At the end of a transfer, it generates the stop condition.

21.3.6.4 Slave Transmitter

This mode can only be entered from the slave receiver mode. With either of the address formats (Figure 21-8 (a), (b), and (c)), the slave transmitter is entered if the slave address byte is the same as its own address and bit R/W_ has been transmitted, if R/W_ is high. The slave transmitter shifts the serial data out on the data line SDA in synch with the clock pulses that are generated by the master device. It does not generate the clock but it can hold clock line SCL low while intervention of the CPU is required (XUDF).

21.3.6.5 Slave Receiver

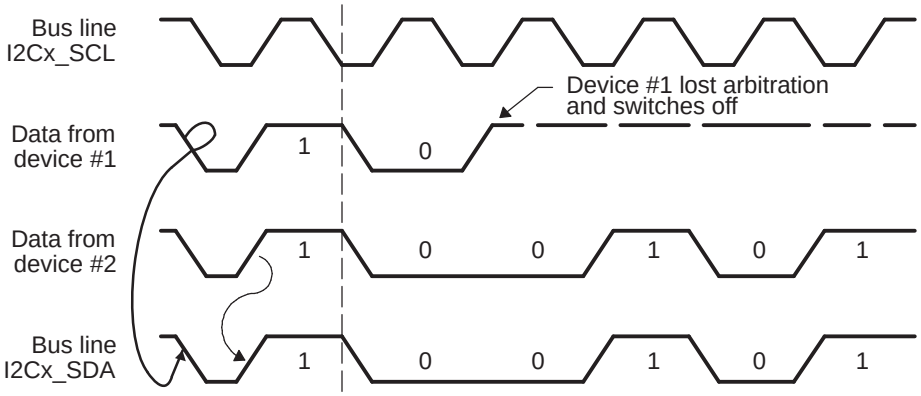
In this mode, serial data bits received on the bus line SDA are shifted-in in synch with the clock pulses on SCL that are generated by the master device. It does not generate the clock but it can hold clock line SCL low while intervention of the CPU is required (ROVR) following the reception of a byte.

Copyright © 2011, Texas Instruments Incorporated

21.3.7 Arbitration

If two or more master transmitters start a transmission on the same bus almost simultaneously, an arbitration procedure is invoked. The arbitration procedure uses the data presented on the serial bus by the competing transmitters. When a transmitter senses that a high signal it has presented on the bus has been overruled by a low signal, it switches to the slave receiver mode, sets the arbitration lost (AL) flag, and generates the arbitration lost interrupt. Figure 21-9 shows the arbitration procedure between two devices. The arbitration procedure gives priority to the device that transmits the serial data stream with the lowest binary value. Should two or more devices send identical first bytes, arbitration continues on the subsequent bytes.

Figure 21-9. Arbitration Procedure Between Two Master Transmitters

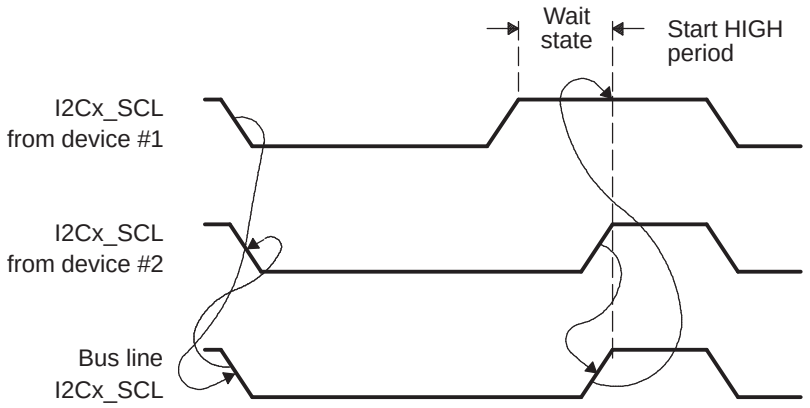


21.3.8 I2C Clock Generation and I2C Clock Synchronization

Under normal conditions, only one master device generates the clock signal, SCL. During the arbitration procedure, however, there are two or more master devices and the clock must be synchronized so that the data output can be compared. The wired-AND property of the clock line means that a device that first generates a low period of the clock line overrules the other devices. At this high/low transition, the clock generators of the other devices are forced to start generation of their own low period. The clock line is then held low by the device with the longest low period, while the other devices that finish their low periods must wait for the clock line to be released before starting their high periods. A synchronized signal on the clock line is thus obtained, where the slowest device determines the length of the low period and the fastest the length of the high period.

If a device pulls down the clock line for a longer time, the result is that all clock generators must enter the WAIT-state. In this way a slave can slow down a fast master and the slow device can create enough time to store a received byte or to prepare a byte to be transmitted. Figure 21-10 illustrates the clock synchronization.

Figure 21-10. Synchronization of Two I2C Clock Generators



Copyright © 2011, Texas Instruments Incorporated

21.3.9 Prescaler (SCLK/ICLK)

The I2C module is operated with a functional clock (SCLK) frequency that can be in a range of 12-100 MHz, according to I2C mode that must be used (an internal ~24 MHz clock (ICLK) is recommended in case of F/S operation mode e). Note that the frequency of the functional clock influences directly the I2C bus performance and timings.

The internal clock used for I2C logic - ICLK - is generated via the I2C prescaler block. The prescaler consists of a 4-bit register - I2C _PSC, and is used to divide the system clock (SCLK) to obtain the internal required clock for the I2C module.

21.3.10 Noise Filter

The noise filter is used to suppress any noise that is 50 ns or less, in the case of F/S mode of operation. It is designed to suppress noise with one ICLK. The noise filter is always one ICLK cycle, regardless of the bus speed. For FS mode (prescaler = 4, ICLK = 24 MHz), the maximum width of the suppressed spikes is 41.6 ns. To ensure a correct filtering, the prescaler must be programmed accordingly.

21.3.11 I2C Interrupts

The I2C module generates 12 types of interrupt: addressed as slave, bus free (stop condition detected), access error, start condition, arbitration-lost, noacknowledge, general call, registers-ready-for-access, receive and transmit data, receive and transmit draining. These 12 interrupts are accompanied with 12 interrupt masks and flags defined in the I2C_IRQENABLE_SET and respectively I2C_IRQSTATUS_RAW registers. Note that all these 12 interrupt events are sharing the same hardware interrupt line.

- Addressed As Slave interrupt (AAS) is generated to inform the Local Host that an external master addressed the module as a slave. When this interrupt occurs, the CPU can check the I2C_ACTOA status register to check which of the 4 own addresses was used by the external master to access the module.
- Bus Free interrupt (BF) is generated to inform the Local Host that the I2C bus became free (when a Stop Condition is detected on the bus) and the module can initiate his own I2C transaction.
- Start Condition interrupt (STC) is generated after the module being in idle mode have detected (synchronously or asynchronously) a possible Start Condition on the bus (signalized with WakeUp).
- Access Error interrupt (AERR) is generated if a Data read access is performed while RX FIFO is empty or a Data write access is performed while TX FIFO is full.
- Arbitration lost interrupt (AL) is generated when the I2C arbitration procedure is lost.
- No-acknowledge interrupt (NACK) is generated when the master I2C does not receive acknowledge from the receiver.
- General call interrupt (GC) is generated when the device detects the address of all zeros (8 bits).
- Registers-ready-for-access interrupt (ARDY) is generated by the I2C when the previously programmed address, data, and command have been performed and the status bits have been updated. This interrupt is used to let the CPU know that the I2C registers are ready for access.
- Receive interrupt/status (RRDY) is generated when there is received data ready to be read by the CPU from the I2C_DATA register (see the FIFO Management subsection for a complete description of required conditions for interrupt generation). The CPU can alternatively poll this bit to read the received data from the I2C_DATA register.
- Transmit interrupt/status (XRDY) is generated when the CPU needs to put more data in the I2C_DATA register after the transmitted data has been shifted out on the SDA pin (see the FIFO Management subsection for a complete description of required conditions for interrupt generation). The CPU can alternatively poll this bit to write the next transmitted data into the I2C_DATA register.
- Receive draining interrupt (RDR) is generated when the transfer length is not a multiple of threshold value, to inform the CPU that it can read the amount of data left to be transferred and to enable the draining mechanism. (see the Draining Feature subsection for additional details).
- Transmit draining interrupt (XDR) is generated when the transfer length is not a multiple of threshold value, to inform the CPU that it can read the amount of data left to be written and to enable the draining mechanism. (see the Draining Feature subsection for additional details).

Copyright © 2011, Texas Instruments Incorporated

When the interrupt signal is activated, the Local Host must read the I2C_IRQSTATUS_RAW register to define the type of the interrupt, process the request, and then write into these registers the correct value to clear the interrupt flag.

21.3.12 DMA Events

The I2C module can generate two DMA requests events, read (I2C_DMA_RX) and write (I2C_DMA_TX) that can be used by the DMA controller to synchronously read received data from the I2C_DATA or write transmitted data to the I2C_DATA register. The DMA read and write requests are generated in a similar manner as RRDY and XRDY, respectively.

The I2C DMA request signals (I2C_DMA_TX and I2C_DMA_RX) are activated according to the FIFO Management subsection.

21.3.13 Interrupt and DMA Events

I2C has two DMA channels (Tx and Rx). For event numbers, see the data manual.

I2C has one interrupt line for all the interrupt requests. For the interrupt number, see the data manual.

21.3.14 FIFO Management

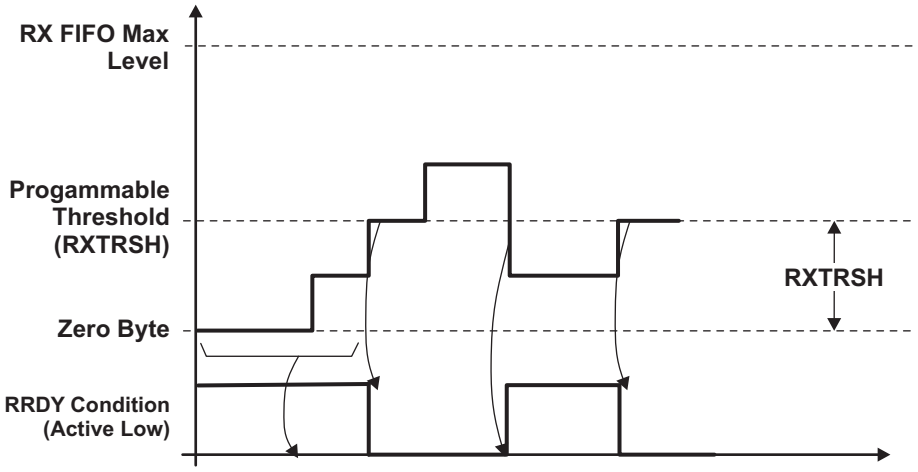
The I2C module implements two internal 32-bytes FIFOs with dual clock for RX and TX modes. The depth of the FIFOs can be configured at integration via a generic parameter which will also be reflected in I2C_IRQSTATUS_RAW.FIFODEPTH register.

21.3.14.1 FIFO Interrupt Mode Operation

In FIFO interrupt mode (relevant interrupts enabled via I2C_IRQENABLE_SET register), the processor is informed of the status of the receiver and transmitter by an interrupt signal. These interrupts are raised when receive/transmit FIFO threshold (defined by I2C_BUF.TXTRSH or I2C_BUF.RXTRSH) are reached; the interrupt signals instruct the Local Host to transfer data to the destination (from the I2C module in receive mode and/or from any source to the I2C FIFO in transmit mode).

Figure 21-11 and Figure 21-12, respectively, illustrate receive and transmit operations from FIFO management point of view.

Figure 21-11. Receive FIFO Interrupt Request Generation

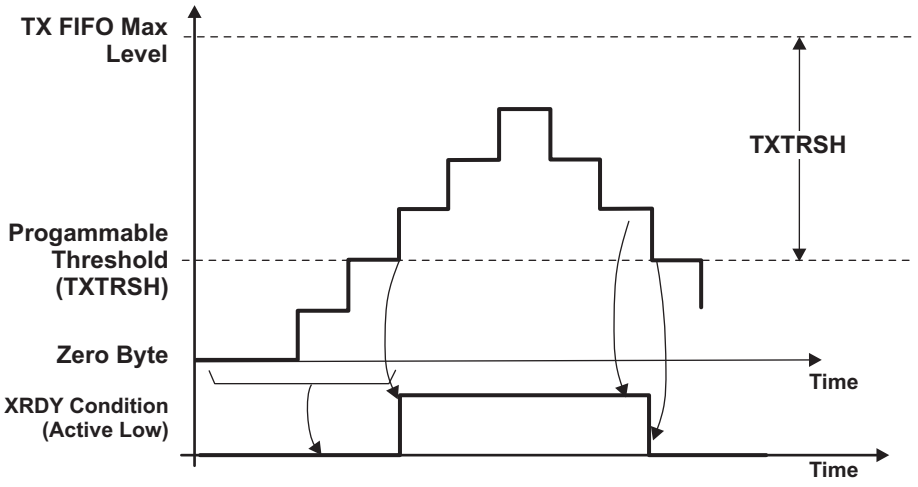


Note that in Figure 21-11, the RRDY Condition illustrates that the condition for generating a RRDY interrupt is achieved. The interrupt request is generated when this signal is active, and it can be cleared only by the CPU by writing a 1 in the corresponding interrupt flag. If the condition is still present after clearing the previous interrupt, another interrupt request will be generated.

Copyright © 2011, Texas Instruments Incorporated

In receive mode, RRDY interrupt is not generated until the FIFO reaches its receive threshold. Once low, the interrupt can only be de-asserted when the Local Host has handled enough bytes to make the FIFO level below threshold. For each interrupt, the Local Host can be configured to read an amount of bytes equal with the value of the RX FIFO threshold + 1.

Figure 21-12. Transmit FIFO Interrupt Request Generation



Note that in the figure above, the XRDY Condition illustrates that the condition for generating a XRDY interrupt is achieved. The interrupt request is generated when this condition is achieved (when TX FIFO is empty, or the TX FIFO threshold is not reached and there are still data bytes to be transferred in the TX FIFO), and it can be cleared only by the CPU by writing a 1 in the corresponding interrupt flag after transmitting the configured number of bytes. If the condition is still present after clearing the previous interrupt, another interrupt request will be generated.

Note that in interrupt mode, the module offers two options for the CPU application to handle the interrupts:

- When detecting an interrupt request (XRDY or RRDY type), the CPU can write/read one data byte to/from the FIFO and then clear the interrupt. The module will not reassert the interrupt until the interrupt condition is not met.
- When detecting an interrupt request (XRDY or RRDY type), the CPU can be programmed to write/read the amount of data bytes specified by the corresponding FIFO threshold (I2C_BUF.TXTRSH + 1 or I2C_BUF.RXTRSH + 1). In this case, the interrupt condition will be cleared and the next interrupt will be asserted again when the XRDY or RRDY condition will be again met.

If the second interrupt serving approach is used, an additional mechanism (draining feature) is implemented for the case when the transfer length is not a multiple of FIFO threshold (see the Draining Feature subsection).

In slave TX mode, the draining feature cannot be used, since the transfer length is not known at the configuration time, and the external master can end the transfer at any point by not acknowledging one data byte.

21.3.14.2 FIFO Polling Mode Operation

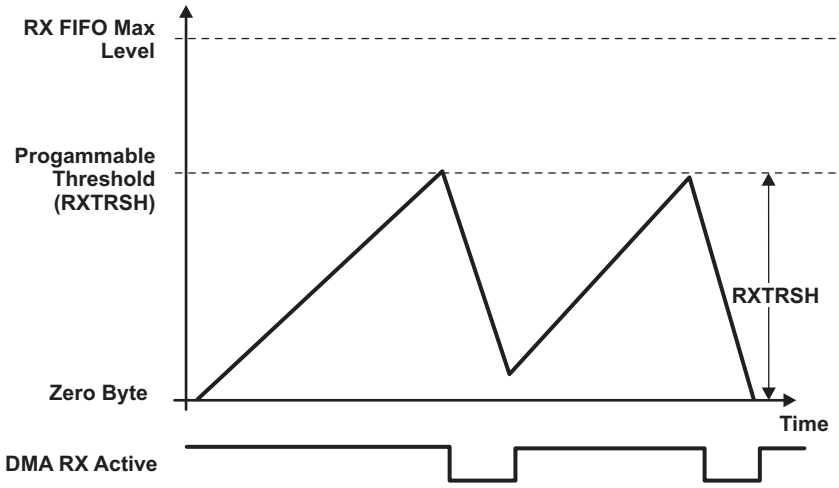
In FIFO polled mode (I2C_IRQENABLE_SET.XRDY_IE and I2C_IRQENABLE_SET.RRDY_IE disabled and DMA disabled), the status of the module (receiver or transmitter) can be checked by polling the XRDY and RRDY status registers (I2C_IRQSTATUS_RAW) (RDR and XDR can also be polled if draining feature must be used). The XRDY and RRDY flags are accurately reflecting the interrupt conditions mentioned in Interrupt Mode. This mode is an alternative to the FIFO interrupt mode of operation, where the status of the receiver and transmitter is automatically known by means of interrupts sent to the CPU.

Copyright © 2011, Texas Instruments Incorporated

21.3.14.3 FIFO DMA Mode Operation

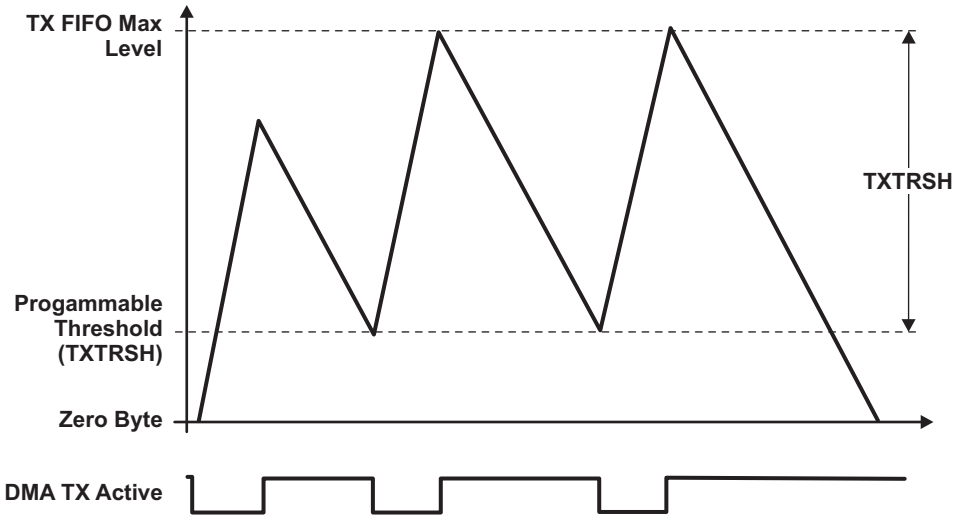
In receive mode, a DMA request is generated as soon as the receive FIFO exceeds its threshold level defined in the threshold level register (I2C_BUF.RXTRSH +1). This request should be de-asserted when the number of bytes defined by the threshold level has been read by the DMA, by setting the I2C_DMARXENABLE_CLR.DMARX_ENABLE_CLEAR field.

Figure 21-13. Receive FIFO DMA Request Generation



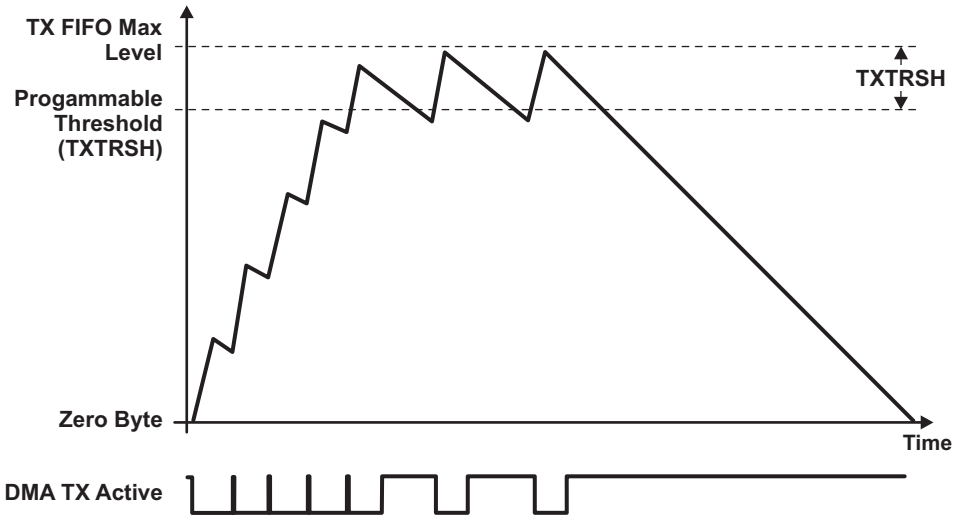
In transmit mode, a DMA request is automatically asserted when the transmit FIFO is empty. This request should be de-asserted when the number of bytes defined by the number in the threshold register (I2C_BUF.TXTHRS+1) has been written in the FIFO by the DMA, by setting the I2C_DMATXENABLE_CLR. DMATX_ENABLE_CLEAR field. If an insufficient number of characters are written, then the DMA request will remain active. Figure 21-14 and Figure 21-15 illustrate DMA TX transfers with different values for TXTRSH.

Figure 21-14. Transmit FIFO DMA Request Generation (High Threshold)



Copyright © 2011, Texas Instruments Incorporated

Figure 21-15. Transmit FIFO DMA Request Generation (Low Threshold)



Note that also in DMA mode it is possible to have a transfer whose length is not multiple of the configured FIFO threshold. In this case, the DMA draining feature is also used for transferring the additional bytes of the transfer (see the Draining Feature subsection for additional details).

According to the desired operation mode, the programmer must set the FIFO thresholds according to the following table (note that only the interface/OCP side thresholds can be programmed; the I2C side thresholds are default equals to 1). Note that the thresholds must be set consistent with the DMA channel length.

In I2C Slave RX Mode, the Local Host can program the RX threshold with the desired value, and use the FIFO draining feature at the end of the I2C transfer to extract from the FIFO the remaining bytes if the threshold is not reached (see the Draining Feature subsection for additional details).

Note that in I2C Slave TX Mode, the TX FIFO threshold should be set to 1 (I2C_BUF.TXTRSH=0, default value), since the length of the transfer may not be known at configuration time. In this way, the interrupt (or accordingly, DMA) requests will be generated for each byte requested by the remote I2C master to be transferred over the I2C bus. This configuration will prevent the I2C core to request additional data from the CPU or from the DMA controller (using IRQ or DMA), data that will eventually not be extracted from the FIFO by the external master (which can use not acknowledge at any time to end the transfer). If the TX threshold is not set to 1, the module will generate an interrupt or assert a DMA only when the external master requests a byte and the FIFO is empty. However, in this case the TX FIFO will require to be cleared at the end of the transfer.

The I2C module offers the possibility to the user to clear the RX or TX FIFO. This is achieved through I2C_BUF.RXFIFO_CLR and I2C_BUF.TXFIFO_CLR registers, which act like software reset for the FIFOs. In DMA mode, these bits will also reset the DMA state machines.

The FIFO clearing feature can be used when the module is configured as a transmitter, the external receiver responds with a NACK in the middle of the transfer, and there is still data in TX FIFO waiting to be transferred.

On the Functional (I2C) domain, the thresholds can always be considered equal to 1. This means that the I2C Core can start transferring data on the I2C bus whenever it has data in the FIFOs (FIFO is not empty).

Copyright © 2011, Texas Instruments Incorporated

21.3.14.4 Draining Feature

The Draining Feature is implemented by the I2C core for handling the end of the transfers whose length is not a multiple of FIFO threshold value, and offers the possibility to transfer the remaining amount of bytes (since the threshold is not reached).

Note that this feature prevents the CPU or the DMA controller to attempt more FIFO accesses than necessary (for example, to generate at the end of a transfer a DMA RX request having in the FIFO less bytes than the configured DMA transfer length). Otherwise, an Access Error interrupt will be generated (see I2C_IRQSTATUS_RAW.AERR interrupt).

The Draining mechanism will generate an interrupt (I2C_IRQSTATUS_RAW.RDR or I2C_IRQSTATUS_RAW.XDR) at the end of the transfer informing the CPU that it needs to check the amount of data left to be transferred (I2C_BUFSTAT.TXSTAT or RXSTAT) and to enable the Draining Feature of the DMA controller if DMA mode is enabled (by re-configuring the DMA transfer length according to this value), or perform only the required number of data accesses, if DMA mode is disabled.

In receiving mode (master or slave), if the RX FIFO threshold is not reached but the transfer was ended on the I2C bus and there is still data left in the FIFO (less than the threshold), the receive draining interrupt (I2C_IRQSTATUS_RAW.RDR) will be asserted to inform the local host that it can read the amount of data in the FIFO (I2C_BUFSTAT.RXSTAT). The CPU will perform a number of data read accesses equal with RXSTAT value (if interrupt or polling mode) or re-configure the DMA controller with the required value in order to drain the FIFO.

In master transmit mode, if the TX FIFO threshold is not reached but the amount of data remaining to be written in the FIFO is less than TXTRSH, the transmit draining interrupt (I2C_IRQSTATUS_RAW.XDR) will be asserted to inform the local host that it can read the amount of data remained to be written in the TX FIFO (I2C_BUFSTAT.TXSTAT). The CPU will need to write the required number of data bytes (specified by TXSTAT value) or re-configure the DMA controller with the required value in order to transfer the last bytes to the FIFO.

Note that in master mode, the CPU can alternatively skip the checking of TXSTAT and RXSTAT values since it can obtain internally this information (by computing DATACOUNT modulo TX/RXTHRSH).

The draining feature is disabled by default, and it can be enabled using I2C_IRQENABLE_SET.XDR_IE or I2C_IRQENABLE_SET.RDR_IE registers (default disabled) only for the transfers with length not equal with the threshold value.

21.3.15 How to Program I2C

21.3.15.1 Module Configuration Before Enabling the Module

1. Program the prescaler to obtain an approximately 12-MHz I2C module clock (I2C_PSC = x; this value is to be calculated and is dependent on the System clock frequency).
2. Program the I2C clock to obtain 100 Kbps or 400 Kbps (SCLL = x and SCLH = x; these values are to be calculated and are dependent on the System clock frequency).
3. Configure its own address (I2C_OA = x) - only in case of I2C operating mode (F/S mode).
4. Take the I2C module out of reset (I2C_CON:I2C_EN = 1).

21.3.15.2 Initialization Procedure

1. Configure the I2C mode register (I2C_CON) bits.
2. Enable interrupt masks (I2C_IRQENABLE_SET), if using interrupt for transmit/receive data.
3. Enable the DMA (I2C_BUF and I2C_DMA/RX/TX/ENABLE_SET) and program the DMA controller) - only in case of I2C operating mode (F/S mode), if using DMA for transmit/receive data.

21.3.15.3 Configure Slave Address and DATA Counter Registers

In master mode, configure the slave address (I2C_SA = x) and the number of byte associated with the transfer (I2C_CNT = x).

Copyright © 2011, Texas Instruments Incorporated

21.3.15.4 Initiate a Transfer

Poll the bus busy (BB) bit in the I2C status register (I2C_IRQSTATUS_RAW). If it is cleared to 0 (bus not busy), configure START/STOP (I2C_CON: STT / I2C_CON: STP condition to initiate a transfer) - only in case of I2C operating mode (F/S mode).

21.3.15.5 Receive Data

Poll the receive data ready interrupt flag bit (RRDY) in the I2C status register (I2C_IRQSTATUS_RAW), use the RRDY interrupt (I2C_IRQENABLE_SET.RRDY_IE set) or use the DMA RX (I2C_BUF.RDMA_EN set together with I2C_DMARXENABLE_SET) to read the received data in the data receive register (I2C_DATA). Use draining feature (I2C_IRQSTATUS_RAW.RDR enabled by I2C_IRQENABLE_SET.RDR_IE)) if the transfer length is not equal with FIFO threshold.

21.3.15.6 Transmit Data

Poll the transmit data ready interrupt flag bit (XRDY) in the I2C status register (I2C_IRQSTATUS_RAW), use the XRDY interrupt (I2C_IRQENABLE_SET.XRDY_IE set) or use the DMA TX (I2C_BUF.XDMA_EN set together with I2C_DMATXENABLE_SET) to write data into the data transmit register (I2C_DATA). Use draining feature (I2C_IRQSTATUS_RAW.XDR enabled by I2C_IRQENABLE_SET.XDR_IE)) if the transfer length is not equal with FIFO threshold.

Copyright © 2011, Texas Instruments Incorporated

21.4 I2C Registers

NOTE: All bits defined as reserved must be written by software with 0s, for preserving future compatibility. When read, any reserved bit returns 0. Also, note that it is good software practice to use complete mask patterns for setting or testing individually bit fields within a register.

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 21-11. System Configuration Register (I2C_SYSC) Field Descriptions

Bit	Field	Value	Description
31-10	Reserved	0	Reserved
9-8	CLKACTIVITY		Clock Activity selection bits. Those bits (one bit for each clock signal present on the boundary of the module) are set to 1 to disable external clock gating mechanism in Idle Mode.
		0h	Both clocks can be cut off
		1h	Only Interface/OCP clock must be kept active; system clock can be cut off
		2h	Only system clock must be kept active; Interface/OCP clock can be cut off
		3h	Both clocks must be kept active
			Values after reset are low (for both 2 bits).
			Note: If the System (functional) Clock is cut-off, the module will assert a WakeUp event when it will asynchronously detect a Start Condition on the I2C Bus. Note that in this case the first transfer will not be taken into account by the module (NACK will be detected by the external master).
7-5	Reserved	0	Reads return 0h.
4-3	IDLEMODE		Idle Mode selection bits. These two bits are used to select one of the idle mode operation mechanisms.
		0h	Force Idle mode
		1h	No Idle mode
		2h	Smart Idle mode
		3h	smartidle_wakeup
			Value after reset is 00 (Force Idle).
2	ENAWAKEUP		Enable Wakeup control bit. When this bit is set to 1, the module enables its own wakeup mechanism.
		0	Wakeup mechanism is disabled
		1	Wakeup mechanism is enabled
			Value after reset is low.
1	SRST		SoftReset bit. When this bit is set to 1, entire module is reset as for the hardware reset. This bit is automatically cleared to 0 by the core and it is only reset by the hardware reset. During reads, it always returns 0.
		0	Normal mode
		1	The module is reset
			Value after reset is low.
0	AUTOIDLE		Autoidle bit. When this bit is set to 1, the module activates its own idle mode mechanism. By evaluating its internal state, the module can decide to gate part of his internal clock tree in order to improve the overall power consumption.
		0	Auto Idle mechanism is disabled
		1	Auto Idle mechanism is enabled
			Value after reset is high.

21.4.5 I2C Status Raw Register (I2C_IRQSTATUS_RAW)

This register provides core status information for interrupt handling, showing all active events (enabled and not enabled). The fields are read-write. Writing a 1 to a bit will set it to 1, that is, trigger the IRQ (mostly for debug). Writing a 0 will have no effect, that is, the register value will not be modified. Only enabled, active events will trigger an actual interrupt request on the IRQ output line.

Table 21-13. I2C Status Raw Register (I2C_IRQSTATUS_RAW) Field Descriptions

Bit	Field	Value	Description
31-15	Reserved	0	Write 0s for future compatibility. Read returns 0.
14	XDR		Transmit draining IRQ status. I2C Master Transmit mode only. This read/clear only bit is set to 1 when the module is configured as a master transmitter, the TX FIFO level is below the configured threshold (TXTRSH) and the amount of data still to be transferred is less than TXTRSH. When this bit is set to 1 by the core, CPU must read the I2C_BUFSTAT.TXSTAT register in order to check the amount of data that need to be written in the TX FIFO. Then, according to the mode set (DMA or interrupt), the CPU can enable the DMA draining feature of the DMA controller with the number of data bytes to be transferred (I2C_BUFSTAT.TXSTAT), or generate write data accesses according to this value (IRQ mode). The interrupt needs to be cleared after the DMA controller was reconfigured (if DMA mode enabled), or before generating data accesses to the FIFO (if IRQ mode enabled). If the corresponding interrupt was enabled, an interrupt is signaled to the local host. The CPU can also poll this bit. For more details about TDR generation, refer to the FIFO Management subsection. The CPU can only clear this bit by writing a 1 into this register. A write 0 has no effect.
		0	Transmit draining inactive
		1	Transmit draining enabled
			Value after reset is low.
13	RDR		Receive draining IRQ status. I2C Receive mode only. This read/clear only bit is set to 1 when the module is configured as a receiver, a stop condition was received on the bus and the RX FIFO level is below the configured threshold (RXTRSH). When this bit is set to 1 by the core, CPU must read the I2C_BUFSTAT.RXSTAT register in order to check the amount of data left to be transferred from the FIFO. Then, according to the mode set (DMA or interrupt), the CPU needs to enable the draining feature of the DMA controller with the number of data bytes to be transferred (I2C_BUFSTAT.RXSTAT), or generate read data accesses according to this value (IRQ mode). The interrupt needs to be cleared after the DMA controller was reconfigured (if DMA mode enabled), or before generating data accesses to the FIFO (if IRQ mode enabled). If the corresponding interrupt was enabled, an interrupt is signaled to the local host. The CPU can also poll this bit. For more details about RDR generation, refer to the FIFO Management subsection. The CPU can only clear this bit by writing a 1 into this register. A write 0 has no effect.
		0	Receive draining inactive
		1	Receive draining enabled
			Value after reset is low.

Copyright © 2011, Texas Instruments Incorporated

Table 21-13. I2C Status Raw Register (I2C_IRQSTATUS_RAW) Field Descriptions (continued)

Bit	Field	Value	Description
12	BB		This read-only bit indicates the state of the serial bus. In slave mode, on reception of a start condition, the device sets BB to 1. BB is cleared to 0 after reception of a stop condition. In master mode, the software controls BB. To start a transmission with a start condition, MST, TRX, and STT must be set to 1 in the I2C_CON register. To end a transmission with a stop condition, STP must be set to 1 in the I2C_CON register. When BB = 1 and STT = 1, a restart condition is generated.
		0	Bus is free
		1	Bus is occupied
			Value after reset is low.
11	ROVR		Receive overrun status. Writing into this bit has no effect. I2C receive mode only. This read-only bit indicates whether the receiver has experienced overrun. Overrun occurs when the shift register is full and the receive FIFO is full. An overrun condition does not result in a data loss; the peripheral is just holding the bus (low on SCL) and prevents other bytes from being received. ROVR is set to 1 when the I2C has recognized an overrun. ROVR is clear when reading I2C_DATA register, or when resetting the I2C (I2C_CON:I2C_EN = 0).
		0	Normal operation
		1	Receiver overrun
			Value after reset is low.
10	XUDF		Transmit underflow status. Writing into this bit has no effect. I2C transmit mode only. This read-only bit indicates whether the transmitter has experienced underflow. In master transmit mode, underflow occurs when the shift register is empty, the transmit FIFO is empty, and there are still some bytes to transmit (DCOUNT 0). In slave transmit mode, underflow occurs when the shift register is empty, the transmit FIFO is empty, and there are still some bytes to transmit (read request from external I2C master). XUDF is set to 1 when the I2C has recognized an underflow. The core holds the line till the underflow cause has disappeared. XUDF is clear when writing I2C_DATA register or resetting the I2C (I2C_CON:I2C_EN = 0).
		0	Normal operation
		1	Transmit underflow
			Value after reset is low.
9	AAS		Address recognized as slave IRQ status. I2C mode only. This read only bit is set to 1 by the device when it has recognized its own slave address (or one of the alternative own addresses), or an address of all zeros (8 bits). When this bit is set to 1 by the core, an interrupt is signaled to the local host if the interrupt was enabled. This bit can be cleared in 2 ways: • If the interrupt was enabled, it will be cleared by writing 1 into this register (writing 0 has no effect) • If the interrupt was not enabled, the AAS bit is reset to 0 by restart or stop
		0	No action
		1	Address recognized
			Value after reset is low.
8	BF		I2C mode only. This read only bit is set to 1 by the device when the I2C bus became free (after a transfer is ended on the bus – stop condition detected). This interrupt informs the Local Host that it can initiate its own I2C transfer on the bus. When this bit is set to 1 by the core, an interrupt is signaled to the local host if the interrupt was enabled. The CPU can only clear this bit by writing a 1 into this register. Writing 0 has no effect.
		0	No action
		1	Bus Free
			Value after reset is low.

Copyright © 2011, Texas Instruments Incorporated

Table 21-13. I2C Status Raw Register (I2C_IRQSTATUS_RAW) Field Descriptions (continued)

Bit	Field	Value	Description
7	AERR		Access Error IRQ status. I2C mode only. This read/clear only bit is set to 1 by the device if an Interface/OCP write access is performed to I2C_DATA while the TX FIFO is full or if an Interface/OCP read access is performed to the I2C_DATA while the RX FIFO is empty. Note that, when the RX FIFO is empty, a read access will return to the previous read data value. When the TX FIFO is full, a write access is ignored. In both events, the FIFO pointers will not be updated. When this bit is set to 1 by the core, an interrupt is signaled to the local host if the interrupt was enabled. The CPU can only clear this bit by writing a 1 into this register. Writing 0 has no effect.
		0	No action
		1	Access Error
			Value after reset is low.
6	STC		Start Condition IRQ status. I2C mode only. This read/clear only bit is set to 1 by the device if previously the module was in idle mode and a start condition was asynchronously detected on the I2C Bus and signalized with an Wakeup (if the I2C_SYSC.ClockActivity allows the system clock to be cut-off). When the Active Mode will be restored and the interrupt generated, this bit will indicate the reason of the wakeup. **Note 1:** The corresponding interrupt for this bit should be enabled only if the module was configured to allow the possibility of cutting-off the system clock while in Idle State (I2C_SYSC.ClockActivity = 00 or 01). **Note 2:** The first transfer (corresponding to the detected start condition) will be lost (not taken into account by the module) and it will be used only for generating the WakeUp enable for restoring the Active Mode of the module. On the I2C line, the external master which generated the transfer will detect this behavior as a not acknowledge to the address phase and will possibly restart the transfer. The CPU can only clear this bit by writing a 1 into this register. Writing 0 has no effect.
		0	No action
		1	Start Condition detected
			Value after reset is low.
5	GC		General call IRQ status. Set to '1' by core when General call address detected and interrupt signaled to MPUSS. Write '1' to clear. I2C mode only. This read/clear only bit is set to 1 by the device if it detects the address of all zeros (8 bits) (general call). When this bit is set to 1 by the core, an interrupt is signaled to the local host if the interrupt was enabled. The CPU can only clear this bit by writing a 1 into this register. Writing 0 has no effect. **Note:** When this bit is set to 1, AAS also reads as 1.
		0	No general call detected
		1	General call address detected
			Value after reset is low.
4	XRDY		Transmit data ready IRQ status. Set to '1' by core when transmitter and when new data is requested. When set to '1' by core, an interrupt is signaled to MPUSS. Write '1' to clear. Transmit mode only (I2C mode). This read/clear only bit (XRDY) is set to 1 when the I2C peripheral is a master or slave transmitter, the CPU needs to send data through the I2C bus, and the module (transmitter) requires new data to be served. Note that a master transmitter requests new data if the FIFO TX level is below the threshold (TXTRSH) and the required amount of data remained to be transmitted (I2C_BUFSTAT.TXSTAT) is greater than the threshold. A slave transmitter requests new data when the FIFO TX level is below the threshold (if TXTRSH > 1), or anytime there is a read request from external master (for each acknowledge received from the master), if TXTRSH = 1. When this bit is set to 1 by the core, an interrupt is signaled to the local host if the interrupt was enabled. The CPU can also poll this bit (refer to the FIFO Management subsection for details about XRDY generation). The CPU can only clear this bit by writing a 1 into this register. Writing 0 has no effect. **Note:** If the DMA transmit mode is enabled (I2C_BUF.XDMA_EN is set, together with I2C_DMATXENABLE_SET), this bit is forced to 0 and no interrupt will be generated; instead, a DMA TX request to the main DMA controller of the system is generated.
		0	Transmission ongoing
		1	Transmit data ready
			Value after reset is low.

Table 21-13. I2C Status Raw Register (I2C_IRQSTATUS_RAW) Field Descriptions (continued)

Bit	Field	Value	Description
3	RRDY		Receive mode only (I2C mode). This read/clear only RRDY is set to 1 when the RX FIFO level is above the configured threshold (RXTRSH). When this bit is set to 1 by the core, CPU is able to read new data from the I2C_DATA register. If the corresponding interrupt was enabled, an interrupt is signaled to the local host. The CPU to read the received data in I2C_DATA register can also poll this bit (refer to the FIFO Management subsection for details about RRDY generation). The CPU can only clear this bit by writing a 1 into this register. A write 0 has no effect. If the DMA receive mode is enabled (I2C_BUF.RDMA_EN is set, together with I2C_DMARXENABLE_SET), this bit is forced to 0 and no interrupt will be generated; instead a DMA RX request to the main DMA controller of the system is generated.
		0	Receive FIFO threshold not reached
		1	Receive data ready for read (RX FIFO threshold reached)
			Value after reset is low.
2	ARDY		I2C mode only. This read/clear only bit, when set to 1, indicates that the previously programmed data and command (receive or transmit, master or slave) has been performed and status bit has been updated. The CPU uses this flag to let it know that the I2C registers are ready to be accessed again. The CPU can only clear this bit by writing a 1 into this register. A write 0 has no effect.
			Mode / **Others** / **ARDY Set Condition** I2C Master transmit / STP = 1 / DCOUNT = 0 I2C Master receive / STP = 1 / DCOUNT = 0 and receiver FIFO empty I2C Master transmit / STP = 0 / DCOUNT passed 0 I2C Master receive / STP = 0 / DCOUNT passed 0 and receiver FIFO empty I2C Master transmit / - / Stop or restart condition received from master I2C Slave receive / - / Stop or restart condition and receiver FIFO empty
		0	No action
		1	Access ready
			Value after reset is low.
1	NACK		No acknowledgement IRQ status. Bit is set when No Acknowledge has been received, an interrupt is signaled to MPUSS. Write '1' to clear this bit. I2C mode only. The read/clear only No Acknowledge flag bit is set when the hardware detects No Acknowledge has been received. When a NACK event occurs on the bus, this bit is set to 1, the core automatically ends the transfer and clears the MST/STP bits in the I2C_CON register and the I2C becomes a slave. Clearing the FIFOs from remaining data might be required. The CPU can only clear this bit by writing a 1 into this register. Writing 0 has no effect.
		0	Normal operation
		1	Not Acknowledge detected
			Value after reset is low.
0	AL		Arbitration lost IRQ status. This bit is automatically set by the hardware when it loses the Arbitration in master transmit mode, an interrupt is signaled to MPUSS. During reads, it always returns 0. I2C mode only. The read/clear only Arbitration Lost flag bit is set to 1 when the device (configured in master mode) detects it has lost an arbitration (in Address Phase). This happens when two or more masters initiate a transfer on the I2C bus almost simultaneously or when the I2C attempts to start a transfer while BB (bus busy) is 1. When this is set to 1 due to arbitration lost, the core automatically clears the MST/STP bits in the I2C_CON register and the I2C becomes a slave receiver. The CPU can only clear this bit by writing a 1 to this register. Writing 0 has no effect.
		0	Normal operation
		1	Arbitration lost detected
			Value after reset is low.

21.4.6 I2C Status Register (I2C_IRQSTATUS)

This register provides core status information for interrupt handling, showing all active and enabled events and masking the others. The fields are read-write. Writing a 1 to a bit will clear it to 0, that is, clear the IRQ. Writing a 0 will have no effect, that is, the register value will not be modified. Only enabled, active events will trigger an actual interrupt request on the IRQ output line.

For all the internal fields of the I2C_IRQSTATUS register, the descriptions given in the I2C_IRQSTATUS_RAW subsection are valid.

21.4.9 I2C Wakeup Enable Register (I2C_WE)

Every 1-bit field in the I2C_WE register enables a specific (synchronous) IRQ request source to generate an asynchronous wakeup (on the appropriate swakeup line). When a bit location is set to 1 by the local host, a wakeup is signaled to the local host if the corresponding event is captured by the core of the I2C controller. Value after reset is low (all bits).

NOTE:

- There is no need for an Access Error WakeUp event, since this event occurs only when the module is in Active Mode (for Interface/OCP accesses to FIFO) and is signaled by an interrupt.
- With the exception of Start Condition WakeUp, which is asynchronously detected when the Functional clock is turned-off, all the other WakeUp events require the Functional (System) clock to be enabled.

Table 21-17. I2C Wakeup Enable Register (I2C_WE) Field Descriptions

Bit	Field	Value	Description
31-15	Reserved	0	Reserved
14	XDR_WE		Transmit draining wakeup enable. This read/write bit is used to enable or disable wakeup signal generation when I2C module is in idle mode, the TX FIFO level is below the threshold and the amount of data left to be transferred is less than TXTRSH value. This allows for the module to inform the CPU that it can check the amount of data to be written to the FIFO.
		0	Transmit draining wakeup disabled
		1	Transmit draining wakeup enabled
13	RDR_WE		Receive draining wakeup enable. This read/write bit is used to enable or disable wakeup signal generation when I2C is in idle mode, configured as a receiver, and it has detected a stop condition on the bus but the RX FIFO threshold is not reached (but the FIFO is not empty). This allows for the module to inform the CPU that it can check the amount of data to be transferred from the FIFO.
		0	Receive draining wakeup disabled
		1	Receive draining wakeup enabled
12	Reserved	0	Reserved
11	ROVR_WE		Receive overrun wakeup enable
		0	Receive overrun wakeup disabled
		1	Receive overrun wakeup enabled
10	XUDF_WE		Transmit underflow wakeup enable
		0	Transmit underflow wakeup disabled
		1	Transmit underflow wakeup enabled

Copyright © 2011, Texas Instruments Incorporated

Table 21-17. I2C Wakeup Enable Register (I2C_WE) Field Descriptions (continued)

Bit	Field	Value	Description
9	AAS_WE		Address as slave IRQ wakeup enable. This read/write bit is used to enable or disable wakeup signal generation when I2C module is in idle mode, and external master addresses the I2C module as a slave. This allows for the module to inform the CPU that it can check which of the own addresses was used by the external master to access the I2C core.
		0	Addressed as slave wakeup disabled
		1	Addressed as slave wakeup enabled
8	BF_WE		Bus free IRQ wakeup enable. This read/write bit is used to enable or disable wakeup signal generation when I2C module is in idle mode and the I2C bus became free. This allows for the module to inform the CPU that it can initiate its own transfer on the I2C line.
		0	Bus Free wakeup disabled
		1	Bus Free wakeup enabled
7	Reserved	0	Reserved
6	STC_WE		Start condition IRQ wakeup set. This read/write bit is used to enable or disable wakeup signal generation when I2C module is in idle mode (with the functional clock inactive) and a possible start condition is detected on the I2C line. The STC WakeUp is generated only if the I2C_SYSC.ClockActivity field indicates that the functional clock can be disabled. Note that if the functional clock is not active, the start condition is asynchronously detected (no filtering and synchronization is used). For this reason, it is possible that the signalized start condition to be a glitch. If the functional clock cannot be disabled (I2C_SYSC.ClockActivity = 10 or 11), the programmer should not enable this wakeup, since the module has other synchronously detected WakeUp event that might be used to exit from idle mode, only if the detected transfer is accessing the I2C module.
		0	Start condition wakeup disabled
		1	Start condition wakeup enabled
5	GC_WE		General call IRQ wakeup enable. This read/write bit is used to enable or disable wakeup signal generation when I2C module is in idle mode and a general call is received on I2C line.
		0	General call wakeup disabled
		1	General call wakeup enabled
4	Reserved	0	Reserved
3	DRDY_WE		Receive/Transmit data ready IRQ wakeup enable. This read/write bit is used to enable or disable wakeup signal generation when I2C module is involved into a long transfer and no more registers accesses are performed on the interface (for example module are set in F/S I2C master transmitter mode and FIFO is full). If in the middle of such a transaction, the FIFO buffer needs more data to be transferred, CPU must be informed to write (in case of transmitter mode) or read (if receiver mode) in/from the FIFO.
		0	Transmit/receive data ready wakeup disabled
		1	Transmit/receive data ready wakeup enabled
2	ARDY_WE		Register access ready IRQ wakeup enable. This read/write bit is used to enable or disable wakeup signal generation when I2C module is involved into a long transfer and no more registers accesses are performed on the interface (for example the module is set in F/S I2C master transmitter mode and FIFO is full). If the current transaction is finished, the module needs to inform CPU about transmission completion.
		0	Register access ready wakeup disabled
		1	Register access ready wakeup enabled
1	NACK_WE		No acknowledgment IRQ wakeup enable. This read/write bit is used to enable or disable wakeup signal generation when I2C module is involved into a long transfer and no more registers accesses are performed on the interface (for example the module is set in F/S I2C master transmitter mode and FIFO is full). If in the middle of such of a transaction a Not Acknowledgment event is raised, the module needs to inform CPU about transmission error.
		0	Not Acknowledge wakeup disabled
		1	Not Acknowledge wakeup enabled

Copyright © 2011, Texas Instruments Incorporated

Table 21-17. I2C Wakeup Enable Register (I2C_WE) Field Descriptions (continued)

Bit	Field	Value	Description
0	AL_WE		Arbitration lost IRQ wakeup enable. This read/write bit is used to enable or disable wakeup signal generation when I2C module is configured as a master and it loses the arbitration. This wake up is very useful when the module is configured as a master transmitter, all the necessary data is provided in the FIFO Tx, STT is enabled and the module enters in Idle Mode. If the module loses the arbitration, an Arbitration Lost event is raised and the module needs to inform CPU about transmission error. **Note:** The AL wakeup must be enabled only for multimaster communication. If the AL_WE is not enabled and the scenario described above occurs, the module will not be able to inform the CPU about the state of the transfer and it will be blocked in an undetermined state.
		0	Arbitration lost wakeup disabled
		1	Arbitration lost wakeup enabled

21.4.10 Receive DMA Enable Set Register (I2C_DMARXENABLE_SET)

The 1-bit field enables a receive DMA request. Writing a 1 to this field will set it to 1. Writing a 0 will have no effect, that is, the register value is not modified. Note that the I2C_BUF.RDMA_EN field is the global (slave) DMA enabler, and that it is disabled by default. The I2C_BUF.RDMA_EN field should also be set to 1 to enable a receive DMA request.

21.4.12 Receive DMA Enable Clear Register (I2C_DMARXENABLE_CLR)

The 1-bit field disables a receive DMA request. Writing a 1 to a bit will clear it to 0. Another result of setting to '1' the DMARX_ENABLE_CLEAR field, is the reset of the DMA RX request and wakeup lines. Writing a 0 will have no effect, that is, the register value is not modified.

R/W-0	R/W-0	R/W-0		R/W-0	R/W-0	R/W-0	

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 21-25. Buffer Configuration Register (I2C_BUF) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved
15	RDMA_EN		Receive DMA channel enable. When this bit is set to 1, the receive DMA channel is enabled and the receive data ready status bit (I2C_IRQSTATUS_RAW: RRDY) is forced to 0 by the core.
		0	Receive DMA channel disabled
		1	Receive DMA channel enabled
			Value after reset is low.
14	RXFIFO_CLR		Receive FIFO clear. When set, receive FIFO is cleared (hardware reset for RX FIFO generated). This bit is automatically reset by the hardware. During reads, it always returns 0.
		0	Normal mode
		1	Rx FIFO is reset
			Value after reset is low.
13-8	RXTRSH	0-3Fh	Threshold value for FIFO buffer in RX mode. The receive threshold value is used to specify the trigger level for data receive transfers. The value is specified from the Interface/OCP point of view.
		0	Receive Threshold value = 1
		1	Receive Threshold value = 2
		-	
		-	
		3Fh	Receive Threshold value = 64
			Value after reset is 00h.
			For the FIFO management description, see the FIFO Management subsection.
			Note1: programmed threshold cannot exceed the actual depth of the FIFO.
			Note2: the threshold must not be changed while a transfer is in progress (after STT was configured or after the module was addressed as a slave).
7	XDMA_EN		Transmit DMA channel enable. When this bit is set to 1, the transmit DMA channel is enabled and the transmit data ready status (I2C_IRQSTATUS_RAW: XRDY) bit is forced to 0 by the core.
		0	Transmit DMA channel disabled
		1	Transmit DMA channel enabled
			Value after reset is low.
6	TXFIFO_CLR		Transmit FIFO clear. When set, transmit FIFO is cleared (hardware reset for TX FIFO). This bit is automatically reset by the hardware. During reads, it always returns 0.
		0	Normal mode
		1	Tx FIFO is reset
			Value after reset is low.

Copyright © 2011, Texas Instruments Incorporated

Table 21-25. Buffer Configuration Register (I2C_BUF) Field Descriptions (continued)

Bit	Field	Value	Description
5-0	TXTRSH	0-3Fh	Threshold value for FIFO buffer in TX mode. The Transmit Threshold value is used to specify the trigger level for data transfers. The value is specified from the OCP point of view.
		0	Transmit Threshold value = 1
		1	Transmit Threshold value = 2
		-	
		-	
		3Fh	Transmit Threshold value = 64
			Value after reset is 00h
			Note1: programmed threshold cannot exceed the actual depth of the FIFO.
			Note2: the threshold must not be changed while a transfer is in progress (after STT was configured or after the module was addressed as a slave).

21.4.18 Data Counter Register (I2C_CNT)

CAUTION

During an active transfer phase (between STT having been set to 1 and reception of ARDY), no modification must be done in this register. Changing it may result in an unpredictable behavior.

This read/write register is used to control the numbers of bytes in the I2C data payload.

Figure 21-33. Data Counter Register (I2C_CNT)

31	16	15	0
Reserved		DCOUNT	
R-0		R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 21-26. Data Counter Register (I2C_CNT) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved
15-0	DCOUNT	0-FFFFh	Data count. I2C Master Mode only (receive or transmit; F/S). This 16-bit countdown counter decrements by 1 for every byte received or sent through the I2C interface. A write initializes DCOUNT to a saved initial value. A read returns the number of bytes that are yet to be received or sent. A read into DCOUNT returns the initial value only before a start condition and after a stop condition. When DCOUNT reaches 0, the core generates a stop condition if a stop condition was specified (I2C_CON.STP = 1) and the ARDY status flag is set to 1 in the I2C_IRQSTATUS_RAW register. Note that DCOUNT must not be reconfigured after I2C_CON.STT was enabled and before ARDY is received. **Note1:** In case of I2C mode of operation, if I2C_CON.STP = 0, then the I2C asserts SCL = 0 when DCOUNT reaches 0. The CPU can then reprogram DCOUNT to a new value and resume sending or receiving data with a new start condition (restart). This process repeats until the CPU sets to 1 the I2C_CON.STP bit. The ARDY flag is set each time DCOUNT reaches 0 and DCOUNT is reloaded to its initial value.
		0	Data counter = 65536 bytes (216)
		1	Data counter = 1 bytes
		-	
		-	
		FFFFh	Data counter = 65535 bytes (216 - 1) Values after reset are low (all 16 bits). **Note2:** Since for DCOUNT = 0, the transfer length is 65536, the module does not allow the possibility to initiate zero data bytes transfers.

Copyright © 2011, Texas Instruments Incorporated

21.4.19 Data Access Register (I2C_DATA)

This register is the entry point for the local host to read data from or write data to the FIFO buffer.

Figure 21-34. Data Access Register (I2C_DATA)

31	8	7	0
Reserved		DATA	
R-0		R/W-x	

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 21-27. Data Access Register (I2C_DATA) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7-0	DATA	0-FFh	Transmit/Receive data FIFO endpoint. When read, this register contains the received I2C data. When written, this register contains the byte value to transmit over the I2C data. In SYSTEST loop back mode (I2C_SYSTEST: TMODE = 11), this register is also the entry/receive point for the data. Values after reset are unknown (all 8-bits). **Note:** A read access, when the buffer is empty, returns the previous read data value. A write access, when the buffer is full, is ignored. In both events, the FIFO pointers are not updated and an Access Error (AERR) Interrupt is generated.

Copyright © 2011, Texas Instruments Incorporated

21.4.20 I2C Configuration Register (I2C_CON)

CAUTION

During an active transfer phase (between STT having been set to 1 and reception of ARDY), no modification must be done in this register (except STP enable). Changing it may result in an unpredictable behavior.

Table 21-28. I2C Configuration Register (I2C_CON) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved
15	I2C_EN		I2C module enable. When this bit is cleared to 0, the I2C controller is not enabled and reset. When 0, receive and transmit FIFOs are cleared and all status bits are set to their default values. All configuration registers (I2C_IRQENABLE_SET, I2C_IRQWAKE_SET, I2C_BUF, I2C_CNT, I2C_CON, I2C_OA, I2C_SA, I2C_PSC, I2C_SCLL and I2C_SCLH) are not reset, they keep their initial values and can be accessed. The CPU must set this bit to 1 for normal operation.
		0	Controller in reset. FIFO are cleared and status bits are set to their default value.
		1	Module enabled
			Value after reset is low.
14	Reserved	0	Reserved
13-12	OPMODE		Operation mode selection. These two bits select module operation mode.
		0h	I2C Fast/Standard mode
		1h	Reserved
		2h	Reserved
		3h	Reserved
			Value after reset is 00.
11	STB		Start byte mode (I2C master mode only). The start byte mode bit is set to 1 by the CPU to configure the I2C in start byte mode (I2C_SA = 0000 0001). See the Philips I2C spec for more details [1].
		0	Normal mode
		1	Start byte mode
			Value after reset is low.
10	MST		Master/slave mode (I2C mode only). When this bit is cleared, the I2C controller is in the slave mode and the serial clock (SCL) is received from the master device. When this bit is set, the I2C controller is in the master mode and generates the serial clock.
			Note: This bit is automatically cleared at the end of the transfer on a detected stop condition, in case of arbitration lost or when the module is configured as a master but addressed as a slave by an external master.
		0	Slave mode
		1	Master mode
			Value after reset is low.

Table 21-28. I2C Configuration Register (I2C_CON) Field Descriptions (continued)

Bit	Field	Value	Description
9	TRX		Transmitter/receiver mode (i2C master mode only). When this bit is cleared, the I2C controller is in the receiver mode and data on data line SDA is shifted into the receiver FIFO and can be read from I2C_DATA register. When this bit is set, the I2C controller is in the transmitter mode and the data written in the transmitter FIFO via I2C_DATA is shifted out on data line SDA.
		0	Receiver mode
		1	Transmitter mode
			Value after reset is low.
			The operating modes are defined as follows:
			MST / **TRX** / **Operating Modes** 0 / x / Slave receiver 0 / x / Slave transmitter 1 / 0 / Master receiver 1 / 1 / Master transmitter
8	XSA		Expand slave address. (I2C mode only). When set, this bit expands the slave address to 10-bit.
		0	7-bit address mode
		1	10-bit address mode
			Value after reset is low.
7	XOA0		Expand own address 0. (I2C mode only). When set, this bit expands the base own address (OA0) to 10-bit.
		0	7-bit address mode
		1	10-bit address mode
			Value after reset is low.
6	XOA1		Expand own address 1. (I2C mode only). When set, this bit expands the first alternative own address (OA1) to 10-bit.
		0	7-bit address mode
		1	10-bit address mode
			Value after reset is low.
5	XOA2		Expand own address 2. (I2C mode only). When set, this bit expands the second alternative own address (OA2) to 10-bit.
		0	7-bit address mode. (I2C mode only).
		1	10-bit address mode
			Value after reset is low.
4	XOA3		Expand own address 3. When set, this bit expands the third alternative own address (OA3) to 10-bit.
		0	7-bit address mode
		1	10-bit address mode
			Value after reset is low.
3-2	Reserved	0	Reserved
1	STP		Stop condition (I2C master mode only). This bit can be set to a 1 by the CPU to generate a stop condition. It is reset to 0 by the hardware after the stop condition has been generated. The stop condition is generated when DCOUNT passes 0.
			When this bit is not set to 1 before the end of the transfer (DCOUNT = 0), the stop condition is not generated and the SCL line is hold to 0 by the master, which can re-start a new transfer by setting the STT bit to 1.
		0	No action or stop condition detected
		1	Stop condition queried
			Value after reset is low

Copyright © 2011, Texas Instruments Incorporated

Table 21-28. I2C Configuration Register (I2C_CON) Field Descriptions (continued)

Bit	Field	Value	Description
0	STT		Start condition (I2C master mode only). This bit can be set to a 1 by the CPU to generate a start condition. It is reset to 0 by the hardware after the start condition has been generated. The start/stop bits can be configured to generate different transfer formats.
		0	No action or start condition detected
		1	Start condition queried
			Value after reset is low.

STT	STP	Conditions	Bus Activities
1	0	Start	S-A-D
0	1	Stop	P
1	1	Start-Stop (DCOUNT= n)	S-A-D..(n)..D-P
1	0	Start (DCOUNT= n)	S-A-D..(n)..D

Note: DCOUNT is data count value in I2C_CNT register.

21.4.21 I2C Own Address Register (I2C_OA)

CAUTION

During an active transfer phase (between STT having been set to 1 and reception of ARDY), no modification must be done in this register. Changing it may result in an unpredictable behavior.

This register is used to specify the module's base I2C 7-bit or 10-bit address (base own address).

Figure 21-36. I2C Own Address Register (I2C_OA)

31	10	9	0
Reserved		OA	
R-0		R/W-0	

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 21-29. I2C Own Address Register (I2C_OA) Field Descriptions

Bit	Field	Value	Description
31-10	Reserved	0	Reserved
9-0	OA	0-3FFh	Own address. This field specifies either: • A 10-bit address coded on OA [9:0] when XOA (Expand Own Address, I2C_CON[7]) is set to 1. • A 7-bit address coded on OA [6:0] when XOA (Expand Own Address, I2C_CON[7]) is cleared to 0. In this case, OA [9:7] bits must be cleared to 000 by application software. Value after reset is low (all 10 bits).

Copyright © 2011, Texas Instruments Incorporated

21.4.22 I2C Slave Address Register (I2C_SA)

CAUTION

During an active transfer phase (between STT having been set to 1 and reception of ARDY), no modification must be done in this register. Changing it may result in an unpredictable behavior.

This register is used to specify the addressed I2C module 7-bit or 10-bit address (slave address).

Figure 21-37. I2C Own Address Register (I2C_SA)

31	10	9	0
Reserved		SA	
R-0		R/W-3FFh	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 21-30. I2C Slave Address Register (I2C_SA) Field Descriptions

Bit	Field	Value	Description
31-10	Reserved	0	Reserved
9-0	SA	0-3FFh	Slave address. This field specifies either: • A 10-bit address coded on SA [9:0] when XSA (Expand Slave Address, I2C_CON[8]) is set to 1. • A 7-bit address coded on SA [6:0] when XSA (Expand Slave Address, I2C_CON[8]) is cleared to 0. In this case, SA [9:7] bits must be cleared to 000 by application software. Value after reset is low (all 10 bits).

Copyright © 2011, Texas Instruments Incorporated

21.4.23 I2C Clock Prescaler Register (I2C_PSC)

CAUTION

During an active mode (I2C_EN bit in I2C_CON register is set to 1), no modification must be done in this register. Changing it may result in an unpredictable behavior.

This register is used to specify the internal clocking of the I2C peripheral core.

Figure 21-38. I2C Own Address Register (I2C_PSC)

21.4.24 I2C SCL Low Time Register (I2C_SCLL)

CAUTION

During an active mode (I2C_EN bit in I2C_CON register is set to 1), no modification must be done in this register. Changing it may result in an unpredictable behavior.

This register is used to determine the SCL low time value when master.

Figure 21-40. I2C SCL Low Time Register (I2C_SCLL)

Reserved		SLLC	
R-0		R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 21-32. I2C SCL Low Time Register (I2C_SCLL) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7-0	SCLL	0-FFh	Fast/Standard mode SCL low time. I2C master mode only, (FS). This 8-bit value is used to generate the SCL low time value (tLOW) when the peripheral is operated in master mode. t_{LOW} = (SCLL + 7) * I_{CLK} time period, Value after reset is low (all 8 bits).

21.4.25 I2C SCL High Time Register (I2C_SCLH)

CAUTION

During an active mode (I2C_EN bit in I2C_CON register is set to 1), no modification must be done in this register. Changing it may result in an unpredictable behavior.

This register is used to determine the SCL high time value when master.

21.4.26 System Test Register (I2C_SYSTEST)

CAUTION

Never enable this register for normal I2C operation

This register is used to facilitate system-level tests by overriding some of the standard functional features of the peripheral. It allows testing of SCL counters, controlling the signals that connect to I/O pins, or creating digital loop-back for self-test when the module is configured in system test (SYSTEST) mode. It also provides stop/non-stop functionality in the debug mode.

Figure 21-42. System Test Register (I2C_SYSTEST)

31							16

R-1	R-1	R-1	R-0	R-0	R-0	R-0	R-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 21-34. System Test Register (I2C_SYSTEST) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved
15	ST_EN		System test enable. This bit must be set to 1 to permit other system test registers bits to be set.
		0	Normal mode. All others bits in register are read only.
		1	System test enabled. Permit other system test registers bits to be set.
			Value after reset is low.
14	FREE		Free running mode (on breakpoint). This bit is used to determine the state of the I2C controller when a breakpoint is encountered in the HLL debugger.
			Note: This bit can be set independently of ST_EN value. FREE = 0: the I2C controller stops immediately after completion of the on-going bit transfer. Stopping the transfer is achieved by forcing the SCL line low. Note that in this case there will be no status register updates.
			FREE = 1: the I2C interface runs free. When Suspend indication will be asserted, there will be no accesses on the OCP Interface (the CPU is in debug mode) and consequently the FIFOs will reach full/empty state (according to RX or TX modes) and the I2C SDA line will be kept low. Note that the status registers will be updated, but no DMA, IRQ or WakeUp will be generated.
			The status registers likely to be updated in this mode are: I2C_IRQSTATUS_RAW.XRDY, I2C_IRQSTATUS_RAW.RRDY, I2C_IRQSTATUS_RAW.XUDF, I2C_IRQSTATUS_RAW.ROVR, I2C_IRQSTATUS_RAW.ARDY and I2C_IRQSTATUS_RAW.NACK.
		0	Stop mode (on breakpoint condition). If Master mode, it stops after completion of the on-going bit transfer. In slave mode, it stops during the phase transfer when 1 byte is completely transmitted/received.
		1	Free running mode
			Value after reset is low.

Copyright © 2011, Texas Instruments Incorporated

Table 21-34. System Test Register (I2C_SYSTEST) Field Descriptions (continued)

Bit	Field	Value	Description
13-12	TMODE		Test mode select. In normal functional mode (ST_EN = 0), these bits are don't care. They are always read as 00 and a write is ignored.
			In system test mode (ST_EN = 1), these bits can be set according to the following table to permit various system tests.
		0	Functional mode (default)
		1h	Reserved
		2h	Test of SCL counters (SCLL, SCLH, PSC). SCL provides a permanent clock with master mode.
		3h	Loop back mode select + SDA/SCL IO mode select
			Values after reset are low (2 bits).
			SCL counter test mode: in this mode, the SCL pin is driven with a permanent clock as if mastered with the parameters set in the I2C_PSC, I2C_SCLL, and I2C_SCLH registers.
			Loop back mode: in the master transmit mode only, data transmitted out of the I2C_DATA register (write action) is received in the same I2C_DATA register via an internal path through the FIFO buffer. The DMA and interrupt requests are normally generated if enabled.
			SDA/SCL IO mode: in this mode, the SCL IO and SDA IO are controlled via the I2C_SYSTEST [5:0] register bits.
11	SSB		Set status bits. Writing 1 into this bit also sets the 6 read/clear-only status bits contained in I2C_IRQSTATUS_RAW register (bits 5:0) to 1. Writing 0 into this bit doesn't clear status bits that are already set; only writing 1 into a set status bit can clear it (see I2C_IRQSTATUS_RAW operation). This bit must be cleared prior attempting to clear a status bit.
		0	No action
		1	Set all interrupt status bits to 1
			Value after reset is low.
10-9	Reserved	0	Reserved
8	SCL_I_FUNC		SCL line input value (functional mode). This read-only bit returns the logical state taken by the SCL line (either 1 or 0). It is active both in functional and test mode
		Read:0	Read 0 from SCL line
		Read:1	Read 1 from SCL line
			Value after reset is low.
7	SCL_O_FUNC		SCL line output value (functional mode). This read-only bit returns the value driven by the module on the SCL line (either 1 or 0). It is active both in functional and test mode.
		Read:0	Driven 0 on SCL line
		Read:1	Driven 1 on SCL line
			Value after reset is low.
6	SDA_I_FUNC		SDA line input value (functional mode). This read-only bit returns the logical state taken by the SDA line (either 1 or 0). It is active both in functional and test mode.
		Read:0	Read 0 from SDA line
		Read:1	Read 1 from SDA line
			Value after reset is low.
5	SDA_O_FUNC		SDA line output value (functional mode). This read-only bit returns the value driven by the module on the SDA line (either 1 or 0). It is active both in functional and test mode.
		Read:0	Driven 0 to SDA line
		Read:1	Driven 1 to SDA line
			Value after reset is low.
4	Reserved	0	Reserved
3	SCL_I		SCL line sense input value. In normal functional mode (ST_EN = 0), this read-only bit always reads 0. In system test mode (ST_EN = 1 & TMODE = 11), this read-only bit returns the logical state taken by the SCL line (either 1 or 0).
		Read:0	Read 0 from SCL line
		Read:1	Read 1 from SCL line
			Value after reset is low.

Copyright © 2011, Texas Instruments Incorporated

Table 21-34. System Test Register (I2C_SYSTEST) Field Descriptions (continued)

Bit	Field	Value	Description
2	SCL_O		SCL line drive output value. In normal functional mode (ST_EN = 0), this bit is don't care. It always reads 0 and a write is ignored. In system test mode (ST_EN = 1 & TMODE = 11), a 0 forces a low level on the SCL line and a 1 puts the I2C output driver to a high-impedance state.
		Read:0	Forces 0 on the SCL data line
		Read:1	SCL output driver in high-impedance state
			Value after reset is low.
1	SDA_I		SDA line sense input value. In normal functional mode (ST_EN = 0), this read-only bit always reads 0. In system test mode (ST_EN = 1 & TMODE = 11), this read-only bit returns the logical state taken by the SDA line (either 1 or 0).
		Read:0	Read 0 from SDA line
		Read:1	Read 1 from SDA line
			Value after reset is low.
0	SDA_O		SDA line drive output value. In normal functional mode (ST_EN = 0), this bit is don't care. It reads as 0 and a write is ignored. In system test mode (ST_EN = 1 & TMODE = 11), a 0 forces a low level on the SDA line and a 1 puts the I2C output driver to a high-impedance state.
		0	Write 0 to SDA line
		1	Write 1 to SDA line
			Value after reset is low.

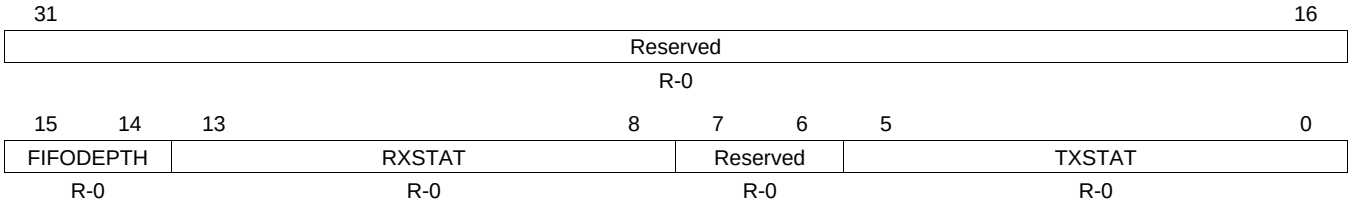
21.4.27 I2C Buffer Status Register (I2C_BUFSTAT)

This read-only register reflects the status of the internal buffers for the FIFO management (see the FIFO Management subsection).

Figure 21-43. I2C Buffer Status Register (I2C_BUFSTAT)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 21-35. I2C Buffer Status Register (I2C_BUFSTAT) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved
15-14	FIFODEPTH		Internal FIFO buffers depth. This read-only bit indicates the internal FIFO buffer depth.
		0	8-bytes FIFO
		1h	16-bytes FIFO
		2h	32-bytes FIFO
		3h	64-bytes FIFO
			Value after reset is given by the boundary module generic parameter.
13-8	RXSTAT	0-3Fh	RX buffer status. This read-only field indicates the number of bytes to be transferred from the FIFO at the end of the I2C transfer (when RDR is asserted). It corresponds to the level indication of the RX FIFO (number of written locations).
			Value after reset is 0.
7-6	Reserved	0	Reserved
5-0	TXSTAT	0-3Fh	TX buffer status. This read-only field indicates the number of data bytes still left to be written in the TX FIFO (it's equal with the initial value of I2C_CNT.DCOUNT minus the number of data bytes already written in the TX FIFO through the OCP Interface).
			Value after reset is equal with 0.

21.4.28 Own Address 1 (OA1) (I2C_OA1)

CAUTION

During an active transfer phase (between STT has been set to 1 and receiving of ARDY), no modification must be done in this register. Changing it may result in an unpredictable behavior.

This register is used to specify the first alternative I2C 7-bit or 10-bit address (own address 1 - OA1).

Bit	Field	Value	Description
31-10	Reserved	0	Reserved
9-0	OA2	0-3FFh	Own address 2. This field specifies either: • A 10-bit address coded on OA2 [9:0] when XOA1 (Expand Own Address 2 - XOA2, I2C_CON[5]) is set to 1. • A 7-bit address coded on OA2 [6:0] when XOA2 (Expand Own Address 2 – XOA2, I2C_CON[5]) is cleared to 0. In this case, OA2 [9:7] bits must be cleared to 000 by application software. Value after reset is low (all 10 bits).

Copyright © 2011, Texas Instruments Incorporated

21.4.30 I2C Own Address 3 Register (I2C_OA3)

CAUTION

During an active transfer phase (between STT has been set to 1 and receiving of ARDY), no modification must be done in this register. Changing it may result in an unpredictable behavior.

This register is used to specify the first alternative I2C 7-bit or 10-bit address (own address 3 - OA3).

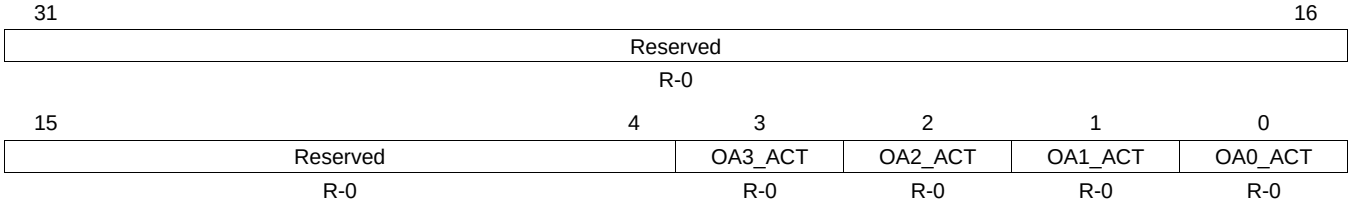
21.4.31 Active Own Address Register (I2C_ACTOA)

This read-only register is used to indicate which one of the module's four own addresses the external master used when addressing the module. The CPU can read this register when the AAS indication was activated. The indication is cleared at the end of the transfer.

Figure 21-47. Active Own Address Register (I2C_ACTOA)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 21-39. Active Own Address Register (I2C_ACTOA) Field Descriptions

Bit	Field	Value	Description
31-4	Reserved	0	Reserved
3	OA3_ACT		Own address 3 active. When a bit location is set to 1 by the core, it signalizes to the Local Host that an external master using the corresponding own address addressed the module.
		0	Own address inactive
		1	Own address active
			Value after reset is low.
2	OA2_ACT		Own address 2 active. When a bit location is set to 1 by the core, it signalizes to the Local Host that an external master using the corresponding own address addressed the module.
		0	Own address inactive
		1	Own address active
			Value after reset is low.
1	OA1_ACT		Own address 1 active. When a bit location is set to 1 by the core, it signalizes to the Local Host that an external master using the corresponding own address addressed the module.
		0	Own address inactive
		1	Own address active
			Value after reset is low.
0	OA0_ACT		Own address 0 active. When a bit location is set to 1 by the core, it signalizes to the Local Host that an external master using the corresponding own address addressed the module.
		0	Own address inactive
		1	Own address active
			Value after reset is low.

Multichannel Audio Serial Port (McASP)

This chapter describes the McASP of the device.

Topic **Page**

22.1 Introduction 4246
22.2 Integration 4248
22.3 Functional Description 4250
22.4 McASP Registers 4303

Copyright © 2011, Texas Instruments Incorporated

22.1 Introduction

22.1.1 Purpose of the Peripheral

The multichannel audio serial port (McASP) functions as a general-purpose audio serial port optimized for the needs of multichannel audio applications. The McASP is useful for time-division multiplexed (TDM) stream, Inter-Integrated Sound (I2S) protocols, and intercomponent digital audio interface transmission (DIT). The McASP consists of transmit and receive sections that may operate synchronized, or completely independently with separate master clocks, bit clocks, and frame syncs, and using different transmit modes with different bit-stream formats. The McASP module also includes serializers that can be individually enabled to either transmit or receive.

22.1.2 Features

Features of the McASP include:

- Two independent clock generator modules for transmit and receive.
  - Clocking flexibility allows the McASP to receive and transmit at different rates. For example, the McASP can receive data at 48 kHz but output up-sampled data at 96 kHz or 192 kHz.
- Independent transmit and receive modules, each includes:
  - Programmable clock and frame sync generator.
  - TDM streams from 2 to 32, and 384 time slots.
  - Support for time slot sizes of 8, 12, 16, 20, 24, 28, and 32 bits.
  - Data formatter for bit manipulation.
- Individually assignable serial data pins (up to 6 pins).
- Glueless connection to audio analog-to-digital converters (ADC), digital-to-analog converters (DAC), codec, digital audio interface receiver (DIR), and S/PDIF transmit physical layer components.
- Wide variety of I2S and similar bit-stream format.
- Integrated digital audio interface transmitter (DIT) supports (up to 10 transmit pins):
  - S/PDIF, IEC60958-1, AES-3 formats.
  - Enhanced channel status/user data RAM.
- 384-slot TDM with external digital audio interface receiver (DIR) device.
  - For DIR reception, an external DIR receiver integrated circuit should be used with I2S output format and connected to the McASP receive section.
- Extensive error checking and recovery.
  - Transmit underruns and receiver overruns due to the system not meeting real-time requirements.
  - Early or late frame sync in TDM mode.
  - Out-of-range high-frequency master clock for both transmit and receive.
  - External error signal coming into the AMUTEIN input.
  - DMA error due to incorrect programming.

22.1.3 Protocols Supported

The McASP supports a wide variety of protocols.

- Transmit section supports:
  - Wide variety of I2S and similar bit-stream formats.
  - TDM streams from 2 to 32 time slots.
  - S/PDIF, IEC60958-1, AES-3 formats.
- Receive section supports:
  - Wide variety of I2S and similar bit-stream formats.
  - TDM streams from 2 to 32 time slots.
  - TDM stream of 384 time slots specifically designed for easy interface to external digital interface

Copyright © 2011, Texas Instruments Incorporated

receiver (DIR) device transmitting DIR frames to McASP using the I2S protocol (one time slot for each DIR subframe).

The transmit and receive sections may each be individually programmed to support the following options on the basic serial protocol:

- Programmable clock and frame sync polarity (rising or falling edge): ACLKR/X, AHCLKR/X, and AFSR/X.
- Slot length (number of bits per time slot): 8, 12, 16, 20, 24, 28, 32 bits supported.
- Word length (bits per word): 8, 12, 16, 20, 24, 28, 32 bits; always less than or equal to the time slot length.
- First-bit data delay: 0, 1, 2 bit clocks.
- Left/right alignment of word inside slot.
- Bit order: MSB first or LSB first.
- Bit mask/pad/rotate function.
  - Automatically aligns data internally in either Q31 or integer formats.
  - Automatically masks nonsignificant bits (sets to 0, 1, or extends value of another bit).

In DIT mode for McASP, additional features of the transmitter are:

- Transmit-only mode 384 time slots (subframe) per frame.
- Bi-phase encoded 3.3 V output.
- Support for consumer and professional applications.
- Channel status RAM (384 bits).
- User data RAM (384 bits).
- Separate valid bit (V) for subframe A, B.

In I2S mode, the transmit and receive sections can support simultaneous transfers on up to all serial data pins operating as 192 kHz stereo channels.

In DIT mode, the transmitter can support a 192 kHz frame rate (stereo) on up to all serial data pins simultaneously (note that the internal bit clock for DIT runs two times faster than the equivalent bit clock for I2S mode, due to the need to generate Biphase Mark Encoded Data).

22.1.4 Unsupported McASP Features

The unsupported McASP features in this device include the following:

- AXR[9:4] — Signals are not pinned out
- AMUTE — Not connected
- AMUTEIN — Not connected

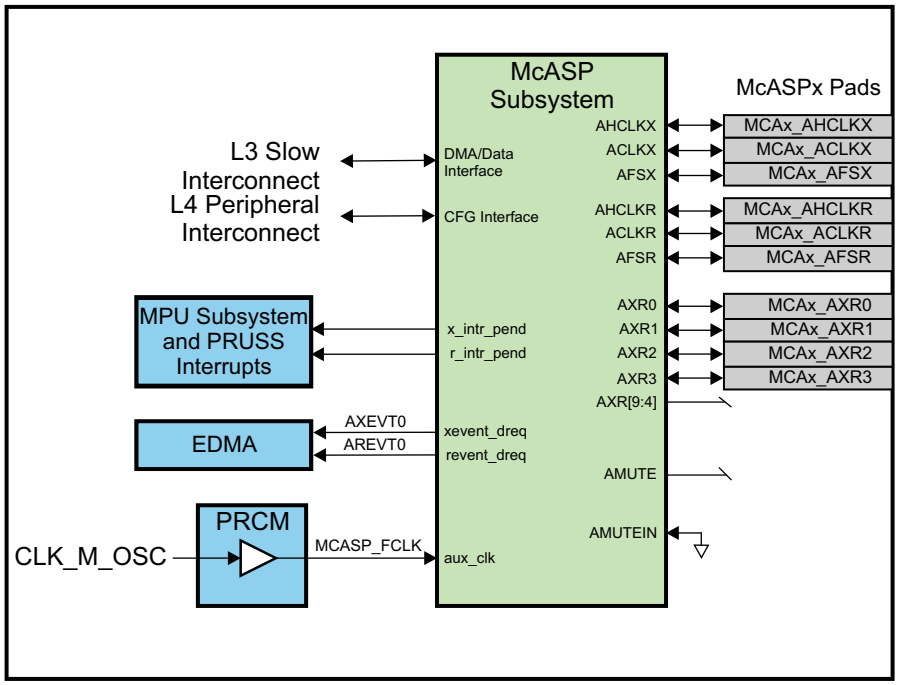
Copyright © 2011, Texas Instruments Incorporated

22.2 Integration

The device contains two instantiations of the McASP subsystem: McASP0 and McASP1. The McASP subsystem includes a McASP peripheral, and transmit/receive buffers.

Each McASP is configured with four serializers.

Figure 22-1. McASP0–1 Integration



22.2.1 McASP Connectivity Attributes

The general connectivity attributes for the McASP modules are summarized in Table 22-1

Table 22-1. McASP Connectivity Attributes

Attributes	Type
Power Domain	Peripheral Domain
Clock Domain	PD_PER_L3S_GCLK (OCP Clock) PD_PER_MCASP_FCLK (Aux Clock)
Reset Signals	PER_DOM_RST_N
Idle/Wakeup Signals	Smart Idle
Interrupt Requests	1 Transmit Interrupt per instance x_intr_pend - to MPU Subsystem (MCATXINTx) and PRUSS (mcasp_x_intr_pend) 1 Receive Interrupt r_intr_pend - to MPU Subsystem (MCARXINTx) and PRUSS (mcasp_r_intr_pend)
DMA Requests	2 DMA requests per instance to EDMA (Transmit: AXEVTx, Receive: AREVTx)
Physical Address	L3 Slow slave port (data) L4 Peripheral slave port (CFG)

Copyright © 2011, Texas Instruments Incorporated

22.2.2 McASP Clock and Reset Management

The McASP module uses functional clocks either generated internally (master mode) or supplied from its serial interface (slave mode). The internal interconnect interface clock is used for the module internal OCP interface. Internal registers select the source of the functional clocks and the applied divider ratio.

Table 22-2. McASP Clock Signals

Clock Signal	Max Freq	Reference / Source	Comments
ocp_clk Interface clock	100 MHz	CORE_COLKOUTM4 / 2	pd_per_l3s_gclk From PRCM
auxclk Functional clock	26 MHz	CLK_M_OSC	pd_per_mcasp_gfclk From PRCM

22.2.3 McASP Pin List

The McASP external interface signals are shown in Table 22-3.

Table 22-3. McASP Pin List

Pin	Type	Description
McASP*x*_AXR[3:0]	I/O	Audio transmit/receive pin
McASP*x*_ACLKX	I/O	Transmit clock
McASP*x*_FSX	I/O	Frame synch for transmit
McASP*x*_AHCLKX	I/O	High speed transmit clock
McASP*x*_ACLKR	I/O	Receive clock

22.3 Functional Description

22.3.1 Overview

Figure 22-2 shows the major blocks of the McASP. The McASP has independent receive/transmit clock generators and frame sync generators, error-checking logic, and up to four serial data pins. See the device-specific data manual for the number of data pins available on your device.

All the McASP pins on the device may be individually programmed as general-purpose I/O (GPIO) if they are not used for serial port functions.

The McASP includes the following pins:

- Serializers;
  - Data pins AXRn: Up to four pins.
- Transmit clock generator:
  - AHCLKX: McASP transmit high-frequency master clock.
  - ACLKX: McASP transmit bit clock.
- Transmit Frame Sync Generator;
  - AFSX: McASP transmit frame sync or left/right clock (LRCLK).
- Receive clock generator;
  - AHCLKR: McASP receive high-frequency master clock.
  - ACLKR: McASP receive bit clock.
- Receive Frame Sync Generator;
  - AFSR: McASP receive frame sync or left/right clock (LRCLK).
- Mute in/out;
  - AMUTEIN: McASP mute input (from external device).
  - AMUTE: McASP mute output.
  - Data pins AXRn.

22.3.3 Industry Standard Compliance Statement

The McASP supports the following industry standard interfaces.

22.3.3.1 TDM Format

The McASP transmitter and receiver support the multichannel, synchronous time-division-multiplexed (TDM) format via the TDM transfer mode. Within this transfer mode, a wide variety of serial data formats are supported, including formats compatible with devices using the Inter-Integrated Sound (I2S) protocol. This section briefly discusses the TDM format and the I2S protocol.

22.3.3.1.1 TDM Format

The TDM format is typically used when communicating between integrated circuit devices on the same printed circuit board or on another printed circuit board within the same piece of equipment. For example, the TDM format is used to transfer data between the processor and one or more analog-to-digital converter (ADC), digital-to-analog converter (DAC), or S/PDIF receiver (DIR) devices.

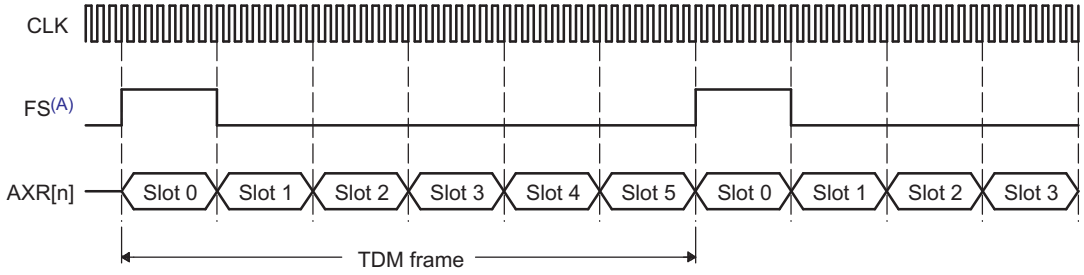
The TDM format consists of three components in a basic synchronous serial transfer: the clock, the data, and the frame sync. In a TDM transfer, all data bits (AXRn) are synchronous to the serial clock (ACLKX or ACLKR). The data bits are grouped into words and slots (as defined in Section 22.3.4). The "slots" are also commonly referred to as "time slots" or "channels" in TDM terminology. A frame consists of multiple slots (or channels). Each TDM frame is defined by the frame sync signal (AFSX or AFSR). Data transfer is continuous and periodic, since the TDM format is most commonly used to communicate with data converters that operate at a fixed sample rate.

There are no delays between slots. The last bit of slot N is followed immediately on the next serial clock cycle with the first bit of slot N + 1, and the last bit of the last slot is followed immediately on the next serial clock with the first bit of the first slot. However, the frame sync may be offset from the first bit of the first slot with a 0, 1, or 2-cycle delay.

It is required that the transmitter and receiver in the system agree on the number of bits per slot, since the determination of a slot boundary is not made by the frame sync signal (although the frame sync marks the beginning of slot 0 and the beginning of a new frame).

Figure 22-8 shows the TDM format. Figure 22-9 shows the different bit delays from the frame sync.

Figure 22-8. TDM Format–6 Channel TDM Example



A FS duration of slot is shown. FS duration of single bit is also supported.

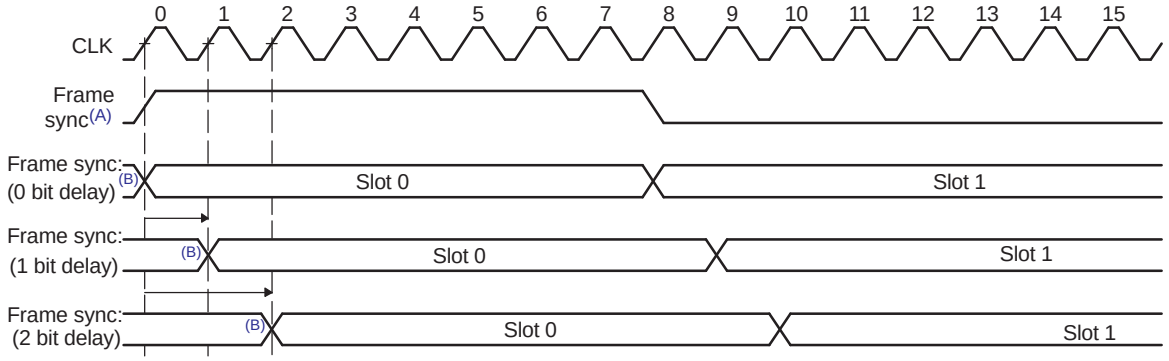
Figure 22-9. TDM Format Bit Delays from Frame Sync



A FS duration of slot is shown. FS duration of single bit is also supported.

B Last bit of last slot of previous frame. No gap between this bit and the first bit of slot 0 is allowed.

In a typical audio system, one frame of data is transferred during each data converter sample period f_s. To support multiple channels, the choices are to either include more time slots per frame (thus operating with a higher bit clock rate), or to use additional data pins to transfer the same number of channels (thus operating with a slower bit clock rate).

For example, a particular six channel DAC may be designed to transfer over a single serial data pin AXRn as shown in Figure 22-8. In this case the serial clock must run fast enough to transfer a total of 6 channels within each frame period. Alternatively, a similar six channel DAC may be designed to use three serial data pins AXR[0,1,2], transferring two channels of data on each pin during each sample period. In the latter case, if the sample period remains the same, the serial clock can run three times slower than the former case. The McASP is flexible enough to support either type of DAC.

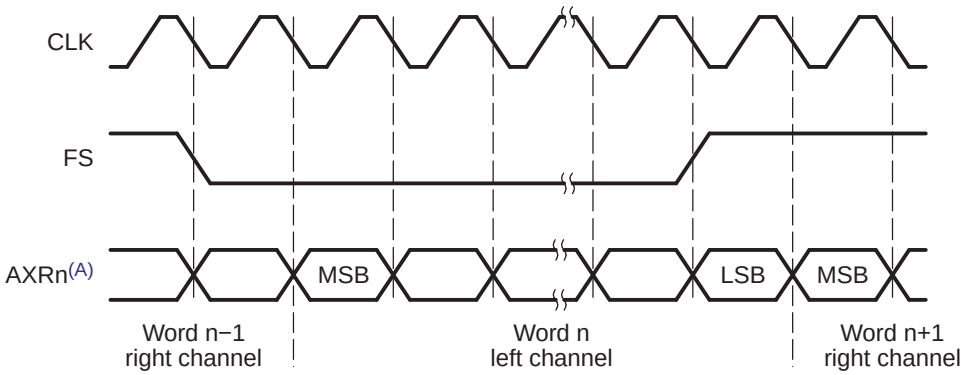
22.3.3.1.2 Inter-Integrated Sound (I2S) Format

The inter-integrated sound (I2S) format is used extensively in audio interfaces. The TDM transfer mode of the McASP supports the I2S format when configured to 2 slots per frame.

I2S format is specifically designed to transfer a stereo channel (left and right) over a single data pin AXRn. "Slots" are also commonly referred to as "channels". The frame width duration in the I2S format is the same as the slot size. The frame signal is also referred to as "word select" in the I2S format. Figure 22-10 shows the I2S protocol.

The McASP supports transfer of multiple stereo channels over multiple AXRn pins.

Figure 22-10. Inter-Integrated Sound (I2S) Format



A 1 to 6 data pins may be supported.

22.3.3.2 S/PDIF Coding Format

The McASP transmitter supports the S/PDIF format with 3.3V biphase-mark encoded output. The S/PDIF format is supported by the digital audio interface transmit (DIT) transfer mode of the McASP. This section briefly discusses the S/PDIF coding format.

22.3.3.2.1 Biphase-Mark Code (BMC)

In S/PDIF format, the digital signal is coded using the biphase-mark code (BMC). The clock, frame, and data are embedded in only one signal—the data pin AXRn. In the BMC system, each data bit is encoded into two logical states (00, 01, 10, or 11) at the pin. These two logical states form a cell. The duration of the cell, which equals to the duration of the data bit, is called a time interval. A logical 1 is represented by two transitions of the signal within a time interval, which corresponds to a cell with logical states 01 or 10. A logical 0 is represented by one transition within a time interval, which corresponds to a cell with logical states 00 or 11. In addition, the logical level at the start of a cell is inverted from the level at the end of the previous cell. Figure 22-11 and Table 22-4 show how data is encoded to the BMC format.

As shown in Figure 22-11, the frequency of the clock is twice the unencoded data bit rate. In addition, the clock is always programmed to 128 × f_s, where f_s is the sample rate (see Section 22.3.3.2.3 for details on how this clock rate is derived based on the S/PDIF format). The device receiving in S/PDIF format can recover the clock and frame information from the BMC signal.

22.3.3.2.2 Subframe Format

Every audio sample transmitted in a subframe consists of 32 S/PDIF time intervals (or cells), numbered from 0 to 31. Figure 22-12 shows a subframe.

- **Time intervals 0-3** carry one of the three permitted preambles to signify the type of audio sample in the current subframe. The preamble is *not* encoded in BMC format, and therefore the preamble code can contain more than two consecutive 0 or 1 logical states in a row. See Table 22-5.
- **Time intervals 4-27** carry the audio sample word in linear 2s-complement representation. The most-significant bit (MSB) is carried by time interval 27. When a 24-bit coding range is used, the least-significant bit (LSB) is in time interval 4. When a 20-bit coding range is used, time intervals 8-27 carry the audio sample word with the LSB in time interval 8. Time intervals 4-7 may be used for other applications and are designated auxiliary sample bits.
- If the source provides fewer bits than the interface allows (either 20 or 24), the unused LSBs are set to logical 0. For a nonlinear PCM audio application or a data application, the main data field may carry any other information.
- **Time interval 28** carries the validity bit (V) associated with the main data field in the subframe.
- **Time interval 29** carries the user data channel (U) associated with the main data field in the subframe.
- **Time interval 30** carries the channel status information (C) associated with the main data field in the subframe. The channel status indicates if the data in the subframe is digital audio or some other type of data.
- **Time interval 31** carries a parity bit (P) such that time intervals 4-31 carry an even number of 1s and an even number of 0s (even parity). As shown in Table 22-5, the preambles (time intervals 0-3) are also defined with even parity.

Figure 22-12. S/PDIF Subframe Format

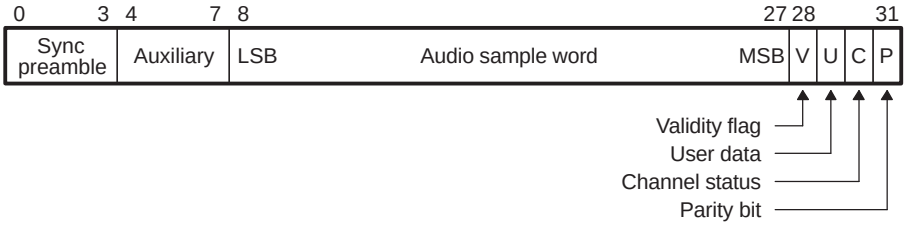

Table 22-5. Preamble Codes

Preamble Code [1]	Previous Logical State	Logical States on pin AXRn [2]	Description
B (or Z)	0	1110 1000	Start of a block and subframe 1
M (or X)	0	1110 0010	Subframe 1
W (or Y)	0	1110 0100	Subframe 2

(1) Historically, preamble codes are referred to as B, M, W. For use in professional applications, preambles are referred to as Z, X, Y, respectively.

(2) The preamble is not BMC encoded. Each logical state is synchronized to the serial clock. These 8 logical states make up time slots (cells) 0 to 3 in the S/PDIF stream.

As shown in Table 22-5, the McASP DIT only generates one polarity of preambles and it assumes the previous logical state to be 0. This is because the McASP assures an even-polarity encoding scheme when transmitting in DIT mode. If an underrun condition occurs, the DIT resynchronizes to the correct logic level on the AXRn pin before continuing with the next transmission.

Copyright © 2011, Texas Instruments Incorporated

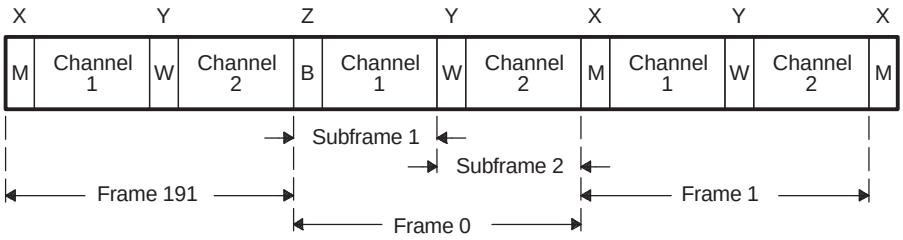
22.3.3.2.3 Frame Format

An S/PDIF frame is composed of two subframes (Figure 22-13). For linear coded audio applications, the rate of frame transmission normally corresponds exactly to the source sampling frequency f_s. The S/PDIF format clock rate is therefore 128 × f_s (128 = 32 cells/subframe × 2 clocks/cell × 2 subframes/sample). For example, for an S/PDIF stream at a 192 kHz sampling frequency, the serial clock is 128 × 192 kHz = 24.58 MHz.

In 2-channel operation mode, the samples taken from both channels are transmitted by time multiplexing in consecutive subframes. Both subframes contain valid data. The first subframe (**left** or **A** channel in stereophonic operation and **primary** channel in monophonic operation) normally starts with preamble M. However, the preamble of the first subframe changes to preamble B once every 192 frames to identify the start of the block structure used to organize the channel status information. The second subframe (**right** or **B** channel in stereophonic operation and **secondary** channel in monophonic operation) always starts with preamble W.

In single-channel operation mode in a professional application, the frame format is the same as in the 2-channel mode. Data is carried in the first subframe and may be duplicated in the second subframe. If the second subframe is not carrying duplicate data, cell 28 (validity bit) is set to logical 1.

Figure 22-13. S/PDIF Frame Format



22.3.4 Definition of Terms

The serial bit stream transmitted or received by the McASP is a long sequence of 1s and 0s, either output or input on one of the audio transmit/receive pins (AXRn). However, the sequence has a hierarchical organization that can be described in terms of frames of data, slots, words, and bits.

A basic synchronous serial interface consists of three important components: clock, frame sync, and data. Figure 22-14 shows two of the three basic components—the clock (ACLK) and the data (AXRn). Figure 22-14 does not specify whether the clock is for transmit (ACLKX) or receive (ACLKR) because the definitions of terms apply to both receive and transmit interfaces. In operation, the transmitter uses ACLKX as the serial clock, and the receiver uses ACLKR as the serial clock. Optionally, the receiver can use ACLKX as the serial clock when the transmitter and receiver of the McASP are configured to operate synchronously.

Bit	A bit is the smallest entity in the serial data stream. The beginning and end of each bit is marked by an edge of the serial clock. The duration of a bit is a serial clock period. A 1 is represented by a logic high on the AXRn pin for the entire duration of the bit. A 0 is represented by a logic low on the AXRn pin for the entire duration of the bit.
Word	A word is a group of bits that make up the data being transferred between the processor and the external device. Figure 22-14 shows an 8-bit word.
Slot	A slot consists of the bits that make up the word, and may consist of additional bits used to pad the word to a convenient number of bits for the interface between the processor and the external device. In Figure 22-14, the audio data consists of only 8 bits of useful data (8-bit word), but it is padded with 4 zeros (12-bit slot) to satisfy the desired protocol in interfacing to an external device. Within a slot, the bits may be shifted in/out of the McASP on the AXRn pin either MSB or LSB first. When the word size is smaller than the slot size, the word may be aligned to the left (beginning) of the slot or to the right (end) of the slot. The additional bits in the slot not belonging to the word may be padded with 0, 1, or with one of the bits (the MSB or the LSB typically) from the data word. These options are shown in Figure 22-15.

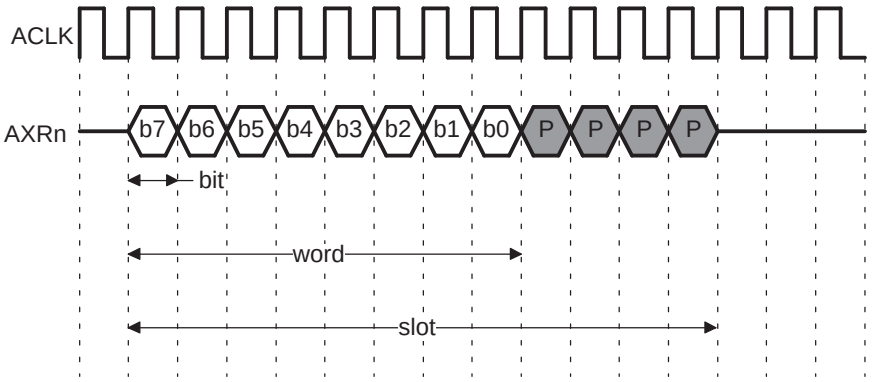
Figure 22-14. Definition of Bit, Word, and Slot

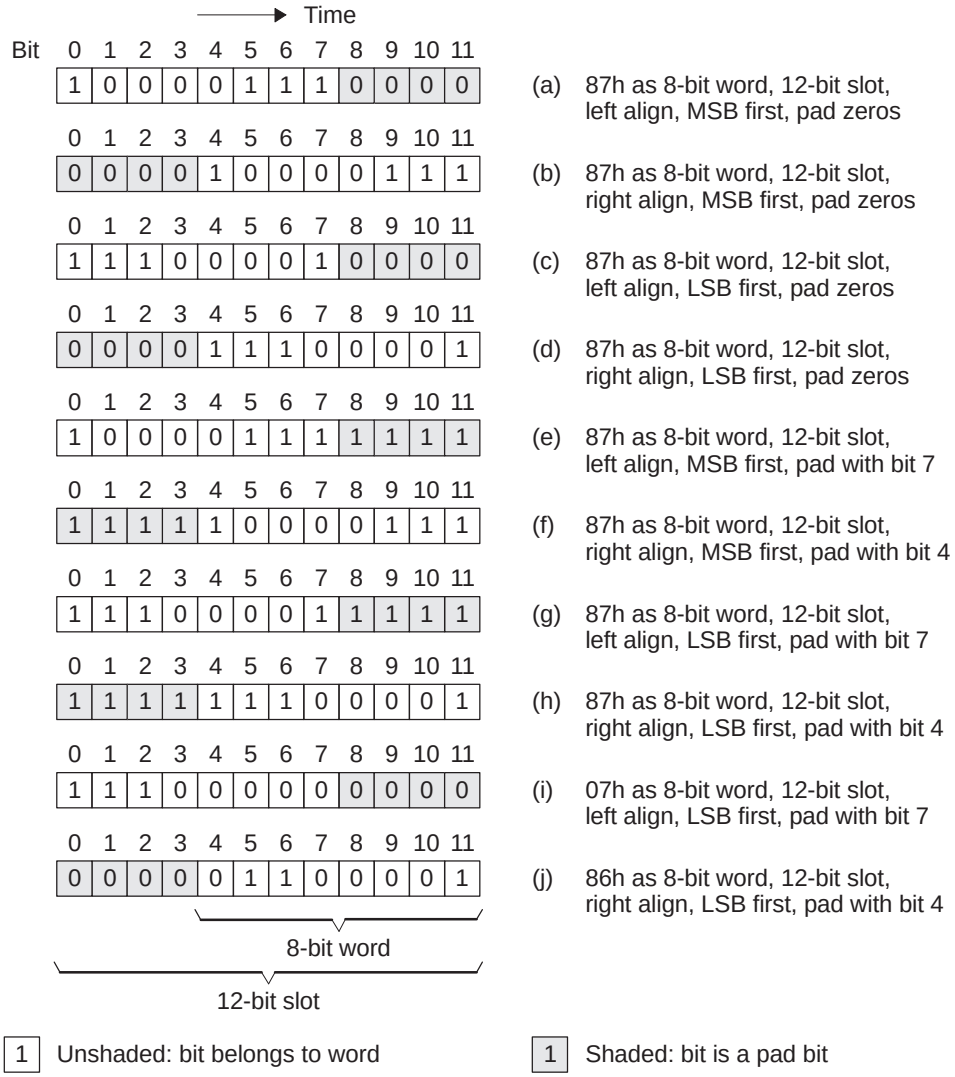


(1) b7:b0 - bits. Bits b7 to b0 form a word.

(2) P - pad bits. Bits b7 to b0, together with the four pad bits, form a slot.

(3) In this example, the data is transmitted MSB first, left aligned.

Figure 22-15. Bit Order and Word Alignment Within a Slot Examples



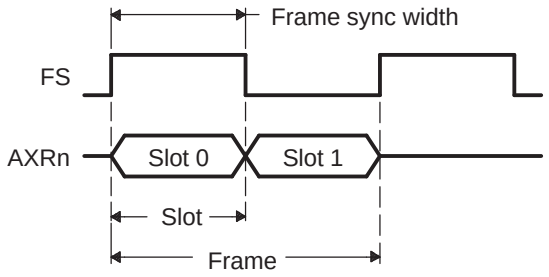
Copyright © 2011, Texas Instruments Incorporated

The third basic element of a synchronous serial interface is the frame synchronization signal, also referred to as frame sync in this document.

Frame A frame contains one or multiple slots, as determined by the desired protocol. Figure 22-16 shows an example frame of data and the frame definitions. Figure 22-16 does not specify whether the frame sync (FS) is for transmit (AFSX) or receive (AFSR) because the definitions of terms apply to both receive and transmit interfaces. In operation, the transmitter uses AFSX and the receiver uses AFSR. Optionally, the receiver can use AFSX as the frame sync when the transmitter and receiver of the McASP are configured to operate synchronously.

This section only shows the generic definition of the frame sync. See Section 22.3.3 and Section 22.3.8.1 for details on the frame sync formats required for the different transfer modes and protocols (burst mode, TDM mode and I2S format, DIT mode and S/PDIF format).

Figure 22-16. Definition of Frame and Frame Sync Width



(1) In this example, there are two slots in a frame, and FS duration of slot length is shown.

Other terms used throughout the document:

TDM	Time-division multiplexed. See Section 22.3.3.1 for details on the TDM protocol.
DIR	Digital audio interface receive. The McASP does not natively support receiving in the S/PDIF format. The McASP supports I2S format output by an external DIR device.
DIT	Digital audio interface transmit. The McASP supports transmitting in S/PDIF format on up to all data pins configured as outputs.
I2S	Inter-Integrated Sound protocol, commonly used on audio interfaces. The McASP supports the I2S protocol as part of the TDM mode (when configured as a 2-slot frame).
Slot or Time Slot	For TDM format, the term time slot is interchangeable with the term slot defined in this section. For DIT format, a McASP time slot corresponds to a DIT subframe.

22.3.5 Clock and Frame Sync Generators

The McASP clock generators are able to produce two independent clock zones: transmit and receive clock zones. The serial clock generators may be programmed independently for the transmit section and the receive section, and may be completely asynchronous to each other. The serial clock (clock at the bit rate) may be sourced:

- Internally - by passing through two clock dividers off the internal clock source (AUXCLK).
- Externally - directly from ACLKR/X pin.
- Mixed - an external high-frequency clock is input to the McASP on either the AHCLKX or AHCLKR pins, and divided down to produce the bit rate clock.

In the internal/mixed cases, the bit rate clock is generated internally and should be driven out on the ACLKX (for transmit) or ACLKR (for receive) pins. In the internal case, an internally-generated high-frequency clock may be driven out onto the AHCLKX or AHCLKR pins to serve as a reference clock for other components in the system.

The McASP requires a minimum of a bit clock and a frame sync to operate, and provides the capability to reference these clocks from an external high-frequency master clock. In DIT mode, it is possible to use only internally-generated clocks and frame syncs. Both the AUXCLK and System Clock are generated from SYSCLK2 (CLKDIV6 domain).

Copyright © 2011, Texas Instruments Incorporated

22.3.5.1 Transmit Clock

The transmit bit clock, ACLKX, (Figure 22-17) may be either externally sourced from the ACLKX pin or internally generated, as selected by the CLKXM bit. If internally generated (CLKXM = 1), the clock is divided down by a programmable bit clock divider (CLKXDIV) from the transmit high-frequency master clock (AHCLKX).

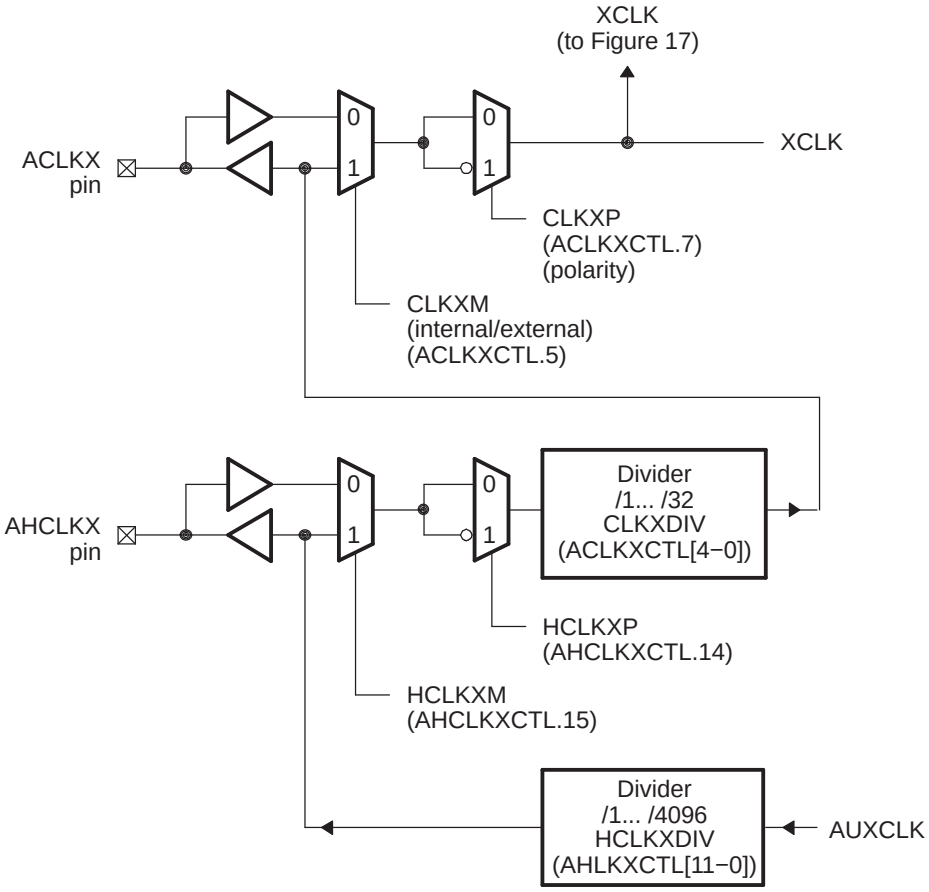
Internally, the McASP always shifts transmit data at the rising edge of the internal transmit clock, XCLK, (Figure 22-17). The CLKXP mux determines if ACLKX needs to be inverted to become XCLK. If CLKXP = 0, the CLKXP mux directly passes ACLKX to XCLK. As a result, the McASP shifts transmit data at the rising edge of ACLKX. If CLKXP = 1, the CLKX mux passes the inverted version of ACLKX to XCLK. As a result, the McASP shifts transmit data at the falling edge of ACLKX.

The transmit high-frequency master clock, AHCLKX, may be either externally sourced from the AHCLKX pin or internally generated, as selected by the HCLKXM bit. If internally generated (HCLKXM = 1), the clock is divided down by a programmable high clock divider (HCLKXDIV) from McASP internal clock source AUXCLK. The transmit high-frequency master clock may be (but is not required to be) output on the AHCLKX pin where it is available to other devices in the system.

The transmit clock configuration is controlled by the following registers:

- ACLKXCTL.
- AHCLKXCTL.

Figure 22-17. Transmit Clock Generator Block Diagram



Copyright © 2011, Texas Instruments Incorporated

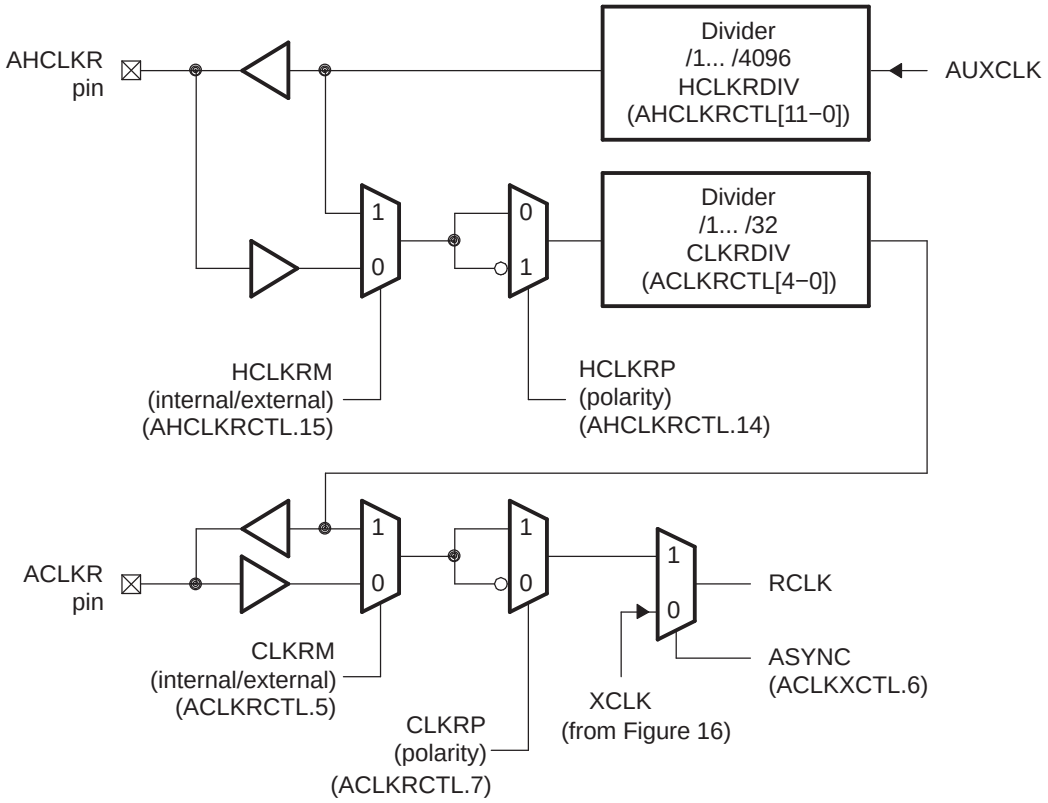
22.3.5.2 Receive Clock

The receiver also has the option to operate synchronously from the ACLKX and AFSX signals. This is achieved when the ASYNC bit in the transmit clock control register (ACLKXCTL) is cleared to 0 (see Figure 22-18). The receiver may be configured with different polarity (CLKRP) and frame sync data delay options from those options of the transmitter.

The receive clock configuration is controlled by the following registers:

- ACLKRCTL.
- AHCLKRCTL.

Figure 22-18. Receive Clock Generator Block Diagram



Copyright © 2011, Texas Instruments Incorporated

22.3.5.3 Frame Sync Generator

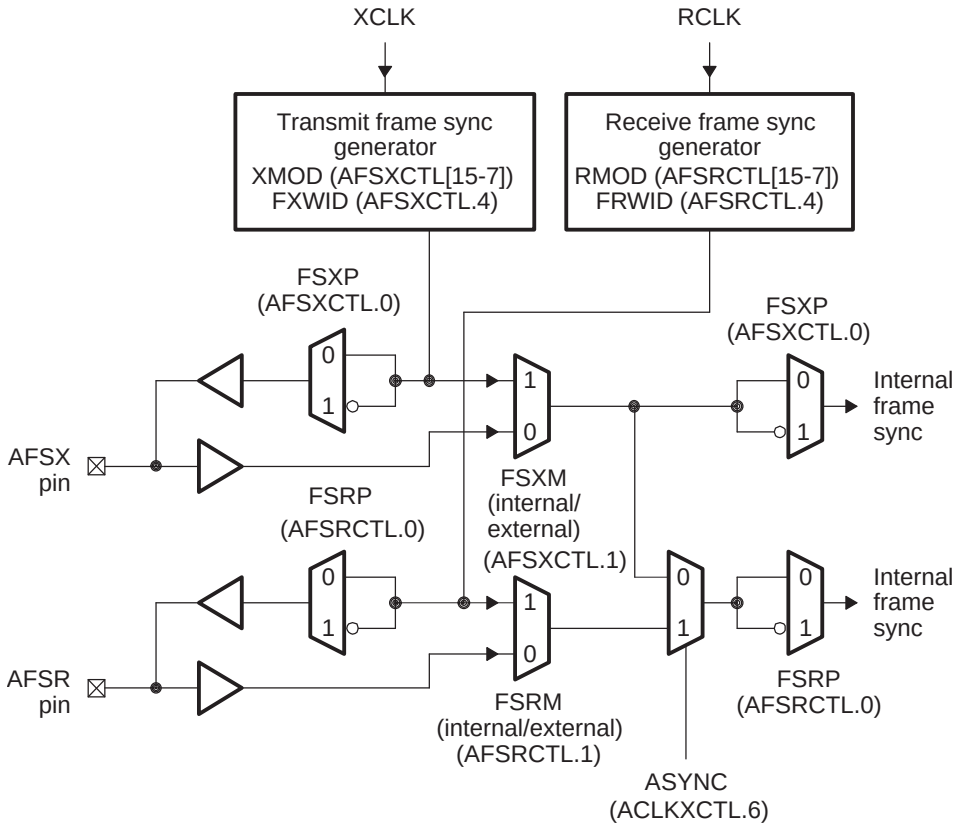
There are two different modes for frame sync: burst and TDM. A block diagram of the frame sync generator is shown in Figure 22-19. The frame sync options are programmed by the receive and transmit frame sync control registers (AFSRCTL and AFSXCTL). The options are:

- Internally-generated or externally-generated.
- Frame sync polarity: rising edge or falling edge.
- Frame sync width: single bit or single word.
- Bit delay: 0, 1, or 2 cycles before the first data bit.

The transmit frame sync pin is AFSX and the receive frame sync pin is AFSR. A typical usage for these pins is to carry the left/right clock (LRCLK) signal when transmitting and receiving stereo data.

Regardless if the AFSX/AFSR is internally generated or externally sourced, the polarity of AFSX/AFSR is determined by FSXP/FSRP, respectively, to be either rising or falling edge. If FSXP/FSRP = 0, the frame sync polarity is rising edge. If FSRP/FSRP = 1, the frame sync polarity is falling edge.

Figure 22-19. Frame Sync Generator Block Diagram



Copyright © 2011, Texas Instruments Incorporated

22.3.5.4 Clocking Examples

Some examples of processes using the McASP clocking and frame flexibility are:

- Receive data from a DVD at 48 kHz, but output up-sampled or decoded audio at 96 kHz or 192 kHz. This could be accomplished by inputting a high-frequency master clock (for example, 512 × receive FS), receiving with an internally-generated bit clock ratio of divide-by-8, and transmitting with an internally-generated bit clock ratio of divide-by-4 or divide-by-2.
- Transmit/receive data based on one sample rate (for example, 44.1 kHz), and transmit/receive data at a different sample rate (for example, 48 kHz).

22.3.6 Signal Descriptions

The signals used on the McASP audio interface are listed in Table 22-6.

Table 22-6. McASP Interface Signals

Pin	I/O/Z	Device Reset ($\overline{\text{RESET}}$ = 0)	Description
		Transmitter Control	
AHCLKX	I/O/Z	Input	Transmit high-frequency master clock
AFSX	I/O/Z	Input	Transmit frame sync or left/right clock (LRCLK)
ACLKX	I/O/Z	Input	Transmit bit clock
		Receiver Control	
AHCLKR	I/O/Z	Input	Receive high-frequency master clock
AFSR	I/O/Z	Input	Receive frame sync or left/right clock (LRCLK)
ACLKR	I/O/Z	Input	Receive bit clock
		Mute	
AMUTE	I/O/Z	Input	Mute output
AMUTEIN	I/O/Z	Input	Mute input
		Data	
AXRn	I/O/Z	Input	TX/RX data pins

22.3.7 Pin Multiplexing

The McASP signals share pins with other processor functions. For detailed information on the McASP pin multiplexing and configuration, see the pin multiplexing information in the device-specific data manual.

Copyright © 2011, Texas Instruments Incorporated

22.3.8 Transfer Modes

22.3.8.1 Burst Transfer Mode

The McASP supports a burst transfer mode, which is useful for nonaudio data such as passing control information between two processors. Burst transfer mode uses a synchronous serial format similar to the TDM mode. The frame sync generation is not periodic or time-driven as in TDM mode, but data driven, and the frame sync is generated for each data word transferred.

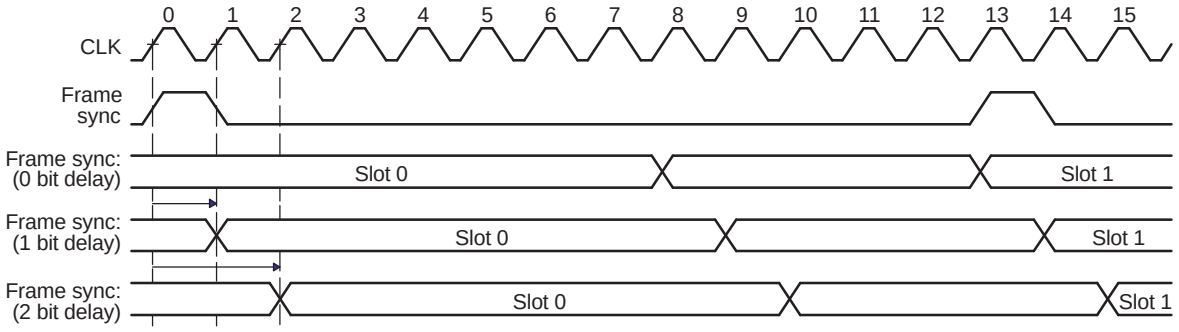
When operating in burst frame sync mode (Figure 22-20), as specified for transmit (XMOD = 0 in AFSXCTL) and receive (RMOD = 0 in AFSRCTL), one slot is shifted for each active edge of the frame sync signal that is recognized. Additional clocks after the slot and before the next frame sync edge are ignored.

In burst frame sync mode, the frame sync delay may be specified as 0, 1, or 2 serial clock cycles. This is the delay between the frame sync active edge and the start of the slot. The frame sync signal lasts for a single bit clock duration (FRWID = 0 in AFSRCTL, FXWID = 0 in AFSXCTL).

For transmit, when generating the transmit frame sync internally, the frame sync begins when the previous transmission has completed and when all the XBUF[n] (for every serializer set to operate as a transmitter) has been updated with new data.

For receive, when generating the receive frame sync internally, frame sync begins when the previous transmission has completed and when all the RBUF[n] (for every serializer set to operate as a receiver) has been read.

Figure 22-20. Burst Frame Sync Mode



The control registers must be configured as follows for the burst transfer mode. The burst mode specific bit fields are in bold face:

- PFUNC: The clock, frame, data pins must be configured for McASP function.
- PDIR: The clock, frame, data pins must be configured to the direction desired.
- PDOUT, PDIN, PDSET, PDCLR: Not applicable. Leave at default.
- GBLCTL: Follow the initialization sequence in Section 22.3.12.2 to configure this register.
- AMUTE: Not applicable. Leave at default.
- DLBCTL: If loopback mode is desired, configure this register according to Section 22.3.10.5, otherwise leave this register at default.
- DITCTL: DITEN must be left at default 0 to select non-DIT mode. Leave the register at default.
- RMASK/XMASK: Mask desired bits according to Section 22.3.9.2 and Section 22.3.10.3.
- RFMT/XFMT: Program all fields according to data format desired. See Section 22.3.10.3.
- AFSRCTL/AFSXCTL: Clear **RMOD/XMOD** bits to 0 to indicate burst mode. Clear **FRWID/FXWID** bits to 0 for single bit frame sync duration. Configure other fields as desired.
- ACLKRCTL/ACLKXCTL: Program all fields according to bit clock desired. See Section 22.3.5.
- AHCLKRCTL/AHCLKXCTL: Program all fields according to high-frequency clock desired. See Section 22.3.5.

Copyright © 2011, Texas Instruments Incorporated

- RTDM/XTDM: Program RTDMS0/XTDMS0 to 1 to indicate one active slot only. Leave other fields at default.
- RINTCTL/XINTCTL: Program all fields according to interrupts desired.
- RCLKCHK/XCLKCHK: Not applicable. Leave at default.
- SRCTLn: Program SRMOD to inactive/transmitter/receiver as desired. DISMOD is not applicable and should be left at default.
- DITCSRA[n], DITCSRB[n], DITUDRA[n], DITUDRB[n]: Not applicable. Leave at default.

22.3.8.2 Time-Division Multiplexed (TDM) Transfer Mode

The McASP time-division multiplexed (TDM) transfer mode supports the TDM format discussed in Section 22.3.3.1.

Transmitting data in the TDM transfer mode requires a minimum set of pins:

- ACLKX - transmit bit clock.
- AFSX - transmit frame sync (or commonly called left/right clock).
- One or more serial data pins, AXRn, whose serializers have been configured to transmit.

The transmitter has the option to receive the ACLKX bit clock as an input, or to generate the ACLKX bit clock by dividing down the AHCLKX high-frequency master clock. The transmitter can either generate AHCLKX internally or receive AHCLKX as an input. See Section 22.3.5.1.

Similarly, to receive data in the TDM transfer mode requires a minimum set of pins:

- ACLKR - receive bit clock.
- AFSR - receive frame sync (or commonly called left/right clock).
- One or more serial data pins, AXRn, whose serializers have been configured to receive.

The receiver has the option to receive the ACLKR bit clock as an input or to generate the ACLKR bit clock by dividing down the AHCLKR high-frequency master clock. The receiver can either generate AHCLKR internally or receive AHCLKR as an input. See Section 22.3.5.2 and Section 22.3.5.3.

The control registers must be configured as follows for the TDM mode. The TDM mode specific bit fields are in bold face:

- PFUNC: The clock, frame, data pins must be configured for McASP function.
- PDIR: The clock, frame, data pins must be configured to the direction desired.
- PDOUT, PDIN, PDSET, PDCLR: Not applicable. Leave at default.
- GBLCTL: Follow the initialization sequence in Section 22.3.12.2 to configure this register.
- AMUTE: Program all fields according to mute control desired.
- DLBCTL: If loopback mode is desired, configure this register according to Section 22.3.10.5, otherwise leave this register at default.
- DITCTL: DITEN must be left at default 0 to select TDM mode. Leave the register at default.
- RMASK/XMASK: Mask desired bits according to Section 22.3.9.2 and Section 22.3.10.3.
- RFMT/XFMT: Program all fields according to data format desired. See Section 22.3.10.3.
- AFSRCTL/AFSXCTL: Set **RMOD/XMOD** bits to 2-32 for TDM mode. Configure other fields as desired.
- ACLKRCTL/ACLKXCTL: Program all fields according to bit clock desired. See Section 22.3.5.
- AHCLKRCTL/AHCLKXCTL: Program all fields according to high-frequency clock desired. See Section 22.3.5.
- RTDM/XTDM: Program all fields according to the time slot characteristics desired.
- RINTCTL/XINTCTL: Program all fields according to interrupts desired.
- RCLKCHK/XCLKCHK: Program all fields according to clock checking desired.
- SRCTLn: Program all fields according to serializer operation desired.
- DITCSRA[n], DITCSRB[n], DITUDRA[n], DITUDRB[n]: Not applicable. Leave at default.

22.3.8.2.1 TDM Time Slots

TDM mode on the McASP can extend to support multiprocessor applications, with up to 32 time slots per frame. For each of the time slots, the McASP may be configured to participate or to be inactive by configuring XTDM and/or RTDM (this allows multiple processors to communicate on the same TDM serial bus).

The TDM sequencer (separate ones for transmit and receive) functions in this mode. The TDM sequencer counts the slots beginning with the frame sync. For each slot, the TDM sequencer checks the respective bit in either XTDM or RTDM to determine if the McASP should transmit/receive in that time slot.

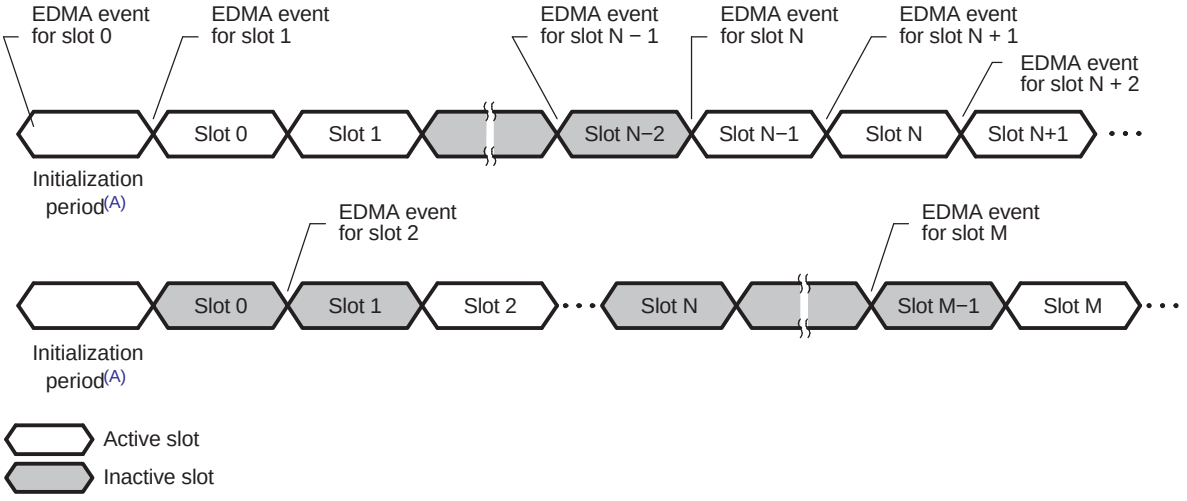
If the transmit/receive bit is active, the McASP functions normally during that time slot; otherwise, the McASP is inactive during that time slot; no update to the buffer occurs, and no event is generated. Transmit pins are automatically set to a high-impedance state, 0, or 1 during that slot, as determined by bit DISMOD in SRCTL[n].

Figure 22-21 shows when the transmit DMA event AXEVT is generated. See Section 22.3.10.1.1 for details on data ready and the initialization period indication. The transmit DMA event for an active time slot (slot N) is generated during the previous time slot (slot N - 1), regardless if the previous time slot (slot N - 1) is active or inactive.

During an active transmit time slot (slot N), if the next time slot (slot N + 1) is configured to be active, the copy from XRBUF[n] to XRSR[n] generates the DMA event for time slot N + 1. If the next time slot (slot N + 1) is configured to be inactive, then the DMA event will be delayed to time slot M - 1. In this case, slot M is the next active time slot. The DMA event for time slot M is generated during the first bit time of slot M - 1.

The receive DMA request generation does not need this capability, since the receive DMA event is generated after data is received in the buffer (looks back in time). If a time slot is disabled, then no data is copied to the buffer for that time slot and no DMA event is generated.

Figure 22-21. Transmit DMA Event (AXEVT) Generation in TDM Time Slots



A See Section 22.3.12.2, step 7a.

22.3.8.2.2 Special 384 Slot TDM Mode for Connection to External DIR

The McASP receiver also supports a 384 time slot TDM mode (DIR mode), to support S/PDIF, AES-3, IEC-60958 receiver ICs whose natural block (block corresponds to McASP frame) size is 384 samples. The advantage to using the 384 time slot TDM mode is that interrupts may be generated synchronous to the S/PDIF, AES-3, IEC-60958, such as the last slot interrupt.

The receive TDM time slot register (RTDM) should be programmed to all 1s during reception of a DIR block. Other TDM functionalities (for example, inactive slots) are not supported (only the slot counter counts the 384 subframes in a block).

To receive data in the DIR mode, the following pins are typically needed:

- ACLKR - receive bit clock.
- AFSR - receive frame sync (or commonly called left/right clock). In this mode, AFSR should be connected to a DIR which outputs a start of block signal, instead of LRCLK.
- One or more serial data pins, AXRn, whose serializers have been configured to receive.

For this special DIR mode, the control registers can be configured just as for TDM mode, except set RMOD in AFSRCTL to 384 to receive 384 time slots.

22.3.8.3 Digital Audio Interface Transmit (DIT) Transfer Mode

In addition to the TDM and burst transfer modes, which are suitable for transmitting audio data between ICs inside the same system, the digital audio interface transmit (DIT) transfer mode of the McASP also supports transmission of audio data in the S/PDIF, AES-3, or IEC-60958 format. These formats are designed to carry audio data between different systems through an optical or coaxial cable. The DIT mode only applies to serializers configured as transmitters, not receivers. See Section 22.3.3.2 for a description of the S/PDIF format.

22.3.8.3.1 Transmit DIT Encoding

The McASP operation in DIT mode is basically identical to the 2 time slot TDM mode, but the data transmitted is output as a biphase mark encoded bit stream, with preamble, channel status, user data, validity, and parity automatically stuffed into the bit stream by the McASP. The McASP includes separate validity bits for even/odd subframes and two 384-bit RAM modules to hold channel status and user data bits.

The transmit TDM time slot register (XTDM) should be programmed to all 1s during DIT mode. TDM functionality is not supported in DIT mode, except that the TDM slot counter counts the DIT subframes.

To transmit data in the DIT mode, the following pins are typically needed:

- AHCLKX - transmit high-frequency master clock.
- One or more serial data pins, AXRn, whose serializers have been configured to transmit.

AHCLKX is optional (the internal clock source may be used instead), but if used as a reference, the processor provides a clock check circuit that continually monitors the AHCLKX input for stability.

If the McASP is configured to transmit in the DIT mode on more than one serial data pin, the bit streams on all pins will be synchronized. In addition, although they will carry unique audio data, they will carry the same channel status, user data, and validity information.

The actual 24-bit audio data must always be in bit positions 23-0 after passing through the first three stages of the transmit format unit.

Copyright © 2011, Texas Instruments Incorporated

For left-aligned Q31 data, the following transmit format unit settings process the data into right aligned 24-bit audio data ready for transmission:

- XROT = 010 (rotate right by 8 bits).
- XRVRS = 0 (no bit reversal, LSB first).
- XMASK = FFFF FF00h-FFFF 0000h (depending upon whether 24, 23, 22, 21, 20, 19, 18, 17, or 16 valid audio data bits are present).
- XPAD = 00 (pad extra bits with 0).

For right-aligned data, the following transmit format unit settings process the data into right aligned 24-bit audio data ready for transmission:

- XROT = 000 (rotate right by 0 bits).
- XRVRS = 0 (no bit reversal, LSB first).
- XMASK = 00FF FFFFh to 0000 FFFFh (depending upon whether 24, 23, 22, 21, 20, 19, 18, 17, or 16 valid audio data bits are present).
- XPAD = 00 (pad extra bits with 0).

22.3.8.3.2 Transmit DIT Clock and Frame Sync Generation

The DIT transmitter only works in the following configuration:

- In transmit frame control register (AFSXCTL):
  - Internally-generated transmit frame sync, FSXM = 1.
  - Rising-edge frame sync, FSXP = 0.
  - Bit-width frame sync, FXWID = 0.
  - 384-slot TDM, XMOD = 1 1000 0000b.
- In transmit clock control register (ACLKXCTL), ASYNC = 1.
- In transmit bitstream format register (XFMT), XSSZ = 1111 (32-bit slot size).

All combinations of AHCLKX and ACLKX are supported.

This is a summary of the register configurations required for DIT mode. The DIT mode specific bit fields are in bold face:

- PFUNC: The data pins must be configured for McASP function. If AHCLKX is used, it must also be configured for McASP function.
- PDIR: The data pins must be configured as outputs. If AHCLKX is used as an input reference, it should be configured as input. If internal clock source AUXCLK is used as the reference clock, it may be output on the AHCLKX pin by configuring AHCLKX as an output.
- PDOUT, PDIN, PDSET, PDCLR: Not applicable for DIT operation. Leave at default.
- GBLCTL: Follow the initialization sequence in Section 22.3.12.2 to configure this register.
- AMUTE: Program all fields according to mute control desired.
- DLBCTL: Not applicable. Loopback is not supported for DIT mode. Leave at default.
- DITCTL: **DITEN** bit must be set to 1 to enable DIT mode. Configure other bits as desired.
- RMASK: Not applicable. Leave at default.
- RFMT: Not applicable. Leave at default.
- AFSRCTL: Not applicable. Leave at default.
- ACLKRCTL: Not applicable. Leave at default.
- AHCLKRCTL: Not applicable. Leave at default.
- RTDM: Not applicable. Leave at default.
- RINTCTL: Not applicable. Leave at default.
- RCLKCHK: Not applicable. Leave at default.
- **XMASK**: Mask desired bits according to the discussion in this section, depending upon left-aligned or right-aligned internal data.

Copyright © 2011, Texas Instruments Incorporated

- **XFMT: XDATDLY** = 0. **XRVRS** = 0. **XPAD** = 0. **XPBIT** = default (not applicable). **XSSZ** = Fh (32-bit slot). XBUSEL = configured as desired. **XROT** bit is configured according to the discussion in this section, either 0 or 8-bit rotate.
- **AFSXCTL**: Configure the bits according to the discussion in this section.
- **ACLKXCTL**: **ASYNC** = 1. Program CLKXDIV bits to obtain the bit clock rate desired. Configure CLKXP and CLKXM bits as desired, because CLKX is not actually used in the DIT protocol.
- **AHCLKXCTL**: Program all fields according to high-frequency clock desired.
- **XTDM**: Set to FFFF FFFFh for all active slots for DIT transfers.
- XINTCTL: Program all fields according to interrupts desired.
- XCLKCHK: Program all fields according to clock checking desired.
- SRCTLn: Set **SRMOD** = 1 (transmitter) for the DIT pins. DISMOD field is don't care for DIT mode.
- **DITCSRA[n], DITCSRB[n]**: Program the channel status bits as desired.
- **DITUDRA[n], DITUDRB[n]**: Program the user data bits as desired.

22.3.8.3.3 DIT Channel Status and User Data Register Files

The channel status registers (DITCSRA*n* and DITCSRB*n*) and user data registers (DITUDRA*n* and DITUDRB*n*) are not double buffered. Typically the programmer uses one of the synchronizing interrupts, such as last slot, to create an event at a safe time so the register may be updated. In addition, the CPU reads the transmit TDM slot counter to determine which word of the register is being used.

It is a requirement that the software avoid writing to the word of user data and channel status that are being used to encode the current time slot; otherwise, it will be indeterminate whether the old or new data is used to encode the bitstream.

The DIT subframe format is defined in Section 22.3.3.2.2. The channel status information (C) and User Data (U) are defined in these DIT control registers:

- DITCSRA0 to DITCSRA5: The 192 bits in these six registers contain the channel status information for the LEFT channel within each frame.
- DITCSRB0 to DITCSRB5: The 192 bits in these six registers contain the channel status information for the RIGHT channel within each frame.
- DITUDRA0 to DITUDRA5: The 192 bits in these six registers contain the user data information for the LEFT channel within each frame.
- DITUDRB0 to DITUDRB5: The 192 bits in these six registers contain the user data information for the RIGHT channel within each frame.

The S/PDIF block format is shown in Figure 22-13. There are 192 frames within a block (frame 0 to frame 191). Within each frame there are two subframes (subframe 1 and 2 for left and right channels, respectively). The channel status and user data information sent on each subframe is summarized in Table 22-7.

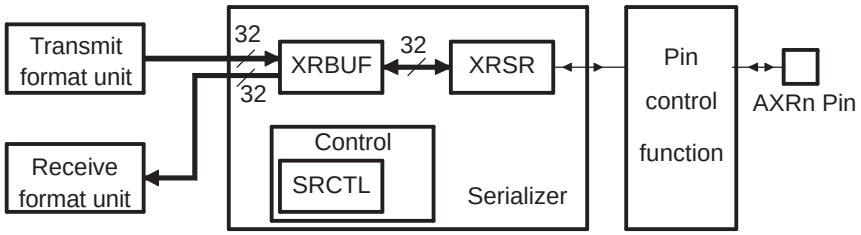
22.3.9 General Architecture

22.3.9.1 Serializers

Figure 22-22 shows the block diagram of the serializer and its interface to other units within the McASP. The serializers take care of shifting serial data in and out of the McASP. Each serializer consists of a shift register (XRSR), a data buffer (XRBUF), a control register (SRCTL), and logic to support the data alignment options of the McASP. For each serializer, there is a dedicated serial data pin (AXRn) and a dedicated control register (SRCTL[n]). The control register allows the serializer to be configured as a transmitter, receiver, or as inactive. When configured as a transmitter the serializer shifts out data to the serial data pin AXRn. When configured as a receiver, the serializer shifts in data from the AXRn pin. The serializer is clocked from the transmit/receive section clock (ACLKX/ACLKR) if configured to transmit/receive respectively.

All serializers that are configured to transmit operate in lock-step. Similarly, all serializers that are configured to receive also operate in lock-step. This means that at most there are two zones per McASP, one for transmit and one for receive.

Figure 22-22. Individual Serializer and Connections Within McASP



For receive, data is shifted in through the AXRn pin to the shift register XRSR. Once the entire slot of data is collected in the XRSR, the data is copied to the data buffer XRBUF. The data is now ready to be read by the processor through the RBUF register, which is an alias of the XRBUF for receive. When the processor reads from the RBUF, the McASP passes the data from RBUF through the receive format unit and returns the formatted data to the processor.

For transmit, the processor services the McASP by writing data into the XBUF register, which is an alias of the XRBUF for transmit. The data automatically passes through the transmit format unit before actually reaching the XRBUF register in the serializer. The data is then copied from XRBUF to XRSR, and shifted out from the AXRn synchronously to the serial clock.

In DIT mode, in addition to the data, the serializer shifts out other DIT-specific information accordingly (preamble, user data, etc.).

The serializer configuration is controlled by SRCTL[n].

22.3.9.2 Format Unit

The McASP has two data formatting units, one for transmit and one for receive. These units automatically remap the data bits within the transmitted and received words between a natural format for the processor (such as a Q31 representation) and the required format for the external serial device (such as "I2S format"). During the remapping process, the format unit also can mask off certain bits or perform sign extension.

Since all transmitters share the same data formatting unit, the McASP only supports one transmit format at a time. For example, the McASP will not transmit in "I2S format" on serializer 0, while transmitting "Left Justified" on serializer 1. Likewise, the receiver section of the McASP only supports one data format at a time, and this format applies to all receiving serializers. However, the McASP can transmit in one format while receiving in a completely different format.

Copyright © 2011, Texas Instruments Incorporated

This formatting unit consists of three stages:

- Bit mask and pad (masks off bits, performs sign extension)
- Rotate right (aligns data within word)
- Bit reversal (selects between MSB first or LSB first)

Figure 22-23 shows a block diagram of the receive formatting unit, and Figure 22-24 shows the transmit formatting unit. Note that the order in which data flows through the three stages is different between the transmit and receive formatting units.

Figure 22-23. Receive Format Unit

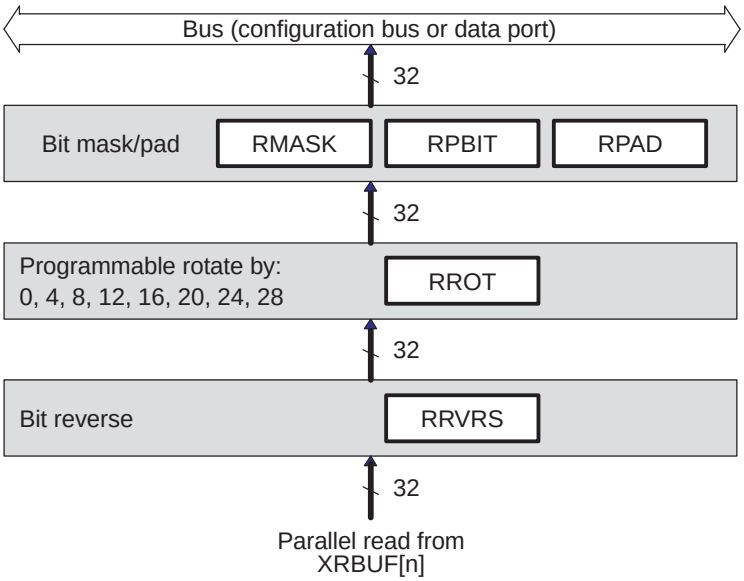


Figure 22-24. Transmit Format Unit

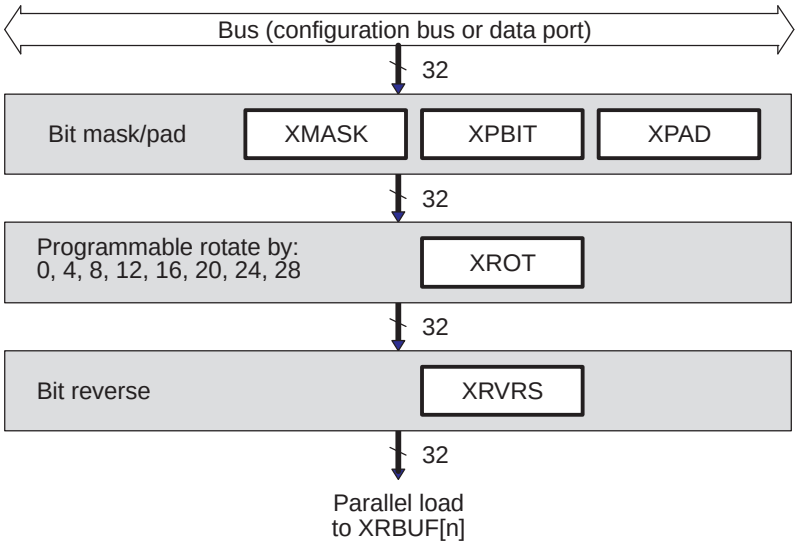


Copyright © 2011, Texas Instruments Incorporated

The bit mask and pad stage includes a full 32-bit mask register, allowing selected individual bits to either pass through the stage unchanged, or be masked off. The bit mask and pad then pad the value of the masked off bits by inserting either a 0, a 1, or one of the original 32 bits as the pad value. The last option allows for sign-extension when the sign bit is selected to pad the remaining bits.

The rotate right stage performs bitwise rotation by a multiple of 4 bits (between 0 and 28 bits), programmable by the (R/X)FMT register. Note that this is a rotation process, not a shifting process, so bit 0 gets shifted back into bit 31 during the rotation.

The bit reversal stage either passes all 32 bits directly through, or swaps them. This allows for either MSB or LSB first data formats. If bit reversal is not enabled, then the McASP will naturally transmit and receive in an LSB first order.

Finally, note that the (R/X)DATDLY bits in (R/X)FMT also determine the data format. For example, the difference between I2S format and left-justified is determined by the delay between the frame sync edge and the first data bit of a given time slot. For I2S format, (R/X)DATDLY should be set to a 1-bit delay, whereas for left-justified format, it should be set to a 0-bit delay.

The combination of all the options in (R/X)FMT means that the McASP supports a wide variety of data formats, both on the serial data lines, and in the internal processor representation.

Section 22.3.10.3 provides more detail and specific examples. The examples use internal representation in integer and Q31 notation, but other fractional notations are also possible.

22.3.9.3 State Machine

The receive and transmit sections have independent state machines. Each state machine controls the interactions between the various units in the respective section. In addition, the state machine keeps track of error conditions and serial port status.

No serial transfers can occur until the respective state machine is released from reset. See initialization sequence for details (Section 22.3.12).

The receive state machine is controlled by the RFMT register, and it reports the McASP status and error conditions in the RSTAT register. Similarly, the transmit state machine is controlled by the XFMT register, and it reports the McASP status and error conditions in the XSTAT register.

22.3.9.4 TDM Sequencer

There are separate TDM sequencers for the transmit section and the receive section. Each TDM sequencer keeps track of the slot count. In addition, the TDM sequencer checks the bits of (R/X)TDM and determines if the McASP should receive/transmit in that time slot.

If the McASP should participate (transmit/receive bit is active) in the time slot, the McASP functions normally. If the McASP should not participate (transmit/receive bit is inactive) in the time slot, no transfers between the XRBUF and XRSR registers in the serializer would occur during that time slot. In addition, the serializers programmed as transmitters place their data output pins in a predetermined state (logic low, high, or high impedance) as programmed by each serializer control register (SRCTL). Refer also to Section 22.3.8.2 for details on how DMA event or interrupt generations are handled during inactive time slots in TDM mode.

The receive TDM sequencer is controlled by register RTDM and reports current receive slot to RSLOT. The transmit TDM sequencer is controlled by register XTDM and reports current transmit slot to XSLOT.

22.3.9.5 Clock Check Circuit

A common source of error in audio systems is a serial clock failure due to instabilities in the off-chip DIR circuit. To detect a clock error quickly, a clock-check circuit is included in the McASP for both transmit and receive clocks, since both may be sourced from off chip.

The clock check circuit can detect and recover from transmit and receive clock failures. See Section 22.3.10.4.6 for implementation and programming details.

Copyright © 2011, Texas Instruments Incorporated

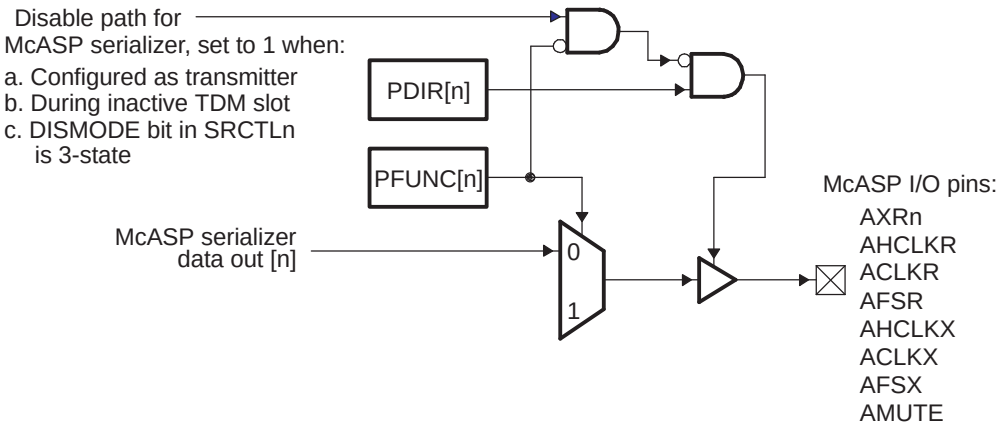
22.3.9.6 Pin Function Control

All McASP pins except AMUTEIN are bidirectional input/output pins. In addition, these bidirectional pins function either as McASP or general-purpose I/O (GPIO) pins. The following registers control the pin functions:

- Pin function register (PFUNC): selects pin to function as McASP or GPIO.
- Pin direction register (PDIR): selects pin to be input or output.
- Pin data input register (PDIN): shows data input at the pin.
- Pin data output register (PDOUT): data to be output at the pin if the pin is configured as GPIO output (PFUNC[n] = 1 and PDIR[n] = 1). Not applicable when the pin is configured as McASP pin (PFUNC[n] = 0).
- Pin data set register (PDSET): alias of PDOUT. Writing a 1 to PDSET[n] sets the respective PDOUT[n] to 1. Writing a 0 has no effect. Applicable only when the pin is configured as GPIO output (PFUNC[n] = 1 and PDIR[n] = 1).
- Pin data clear register (PDCLR): alias of PDOUT. Writing a 1 to PDCLR[n] clears the respective PDOUT[n] to 0. Writing a 0 has no effect. Applicable only when the pin is configured as GPIO output (PFUNC[n] = 1 and PDIR[n] = 1).

See the register descriptions in Section 22.4 for details on the mapping of each McASP pin to the register bits. Figure 22-25 shows the pin control block diagram.

Figure 22-25. McASP I/O Pin Control Block Diagram



22.3.9.6.1 McASP Pin Control-Transmit and Receive

You must correctly set the McASP GPIO registers PFUNC and PDIR, even when McASP pins are used for their serial port (non-GPIO) function.

Serial port functions include:

- Clock pins (ACLKX, ACLKR, AHCLKX, AHCLKR, AFSX, AFSR) used as clock inputs and outputs.
- Serializer data pins (AXRn) used to transmit or receive.
- AMUTE used as a mute output signal.

When using these pins in their serial port function, you must clear PFUNC[n] to 0 for each pin.

Also, certain outputs require PDIR[n] = 1, such as clock pins used as clock outputs, serializer data pins used to transmit, and AMUTE used as mute output.

Clock inputs and serializers configured to receive must have PDIR[n] = 0.

PFUNC and PDIR do not control the AMUTEIN signal, it is usually tied to a device level interrupt pin (consult device datasheet). If used as a mute input, this pin needs to be configured as an input in the appropriate peripheral.

Copyright © 2011, Texas Instruments Incorporated

Finally, there is an important advantage to having separate control of pin direction (by PDIR), and the choice of internal versus external clocking (by CLKRM/CLKXM). Depending on the specific device and usage, you might select an external clock (CLKRM = 0), while enabling the internal clock divider, and the clock pin as an output in the PDIR register (PDIR[ACLKR] = 1). In this case, the bit clock is an output (PDIR[ACLKR] = 1) and, therefore, routed to the ACLKR pin. However, because CLKRM = 0, the bit clock is then routed back to the McASP module as an "external" clock source. This may result in less skew between the clock inside the McASP and the clock in the external device, thus producing more balanced setup and hold times for a particular system. As a result, this may allow a higher serial clock rate interface.

22.3.10 Operation

This section discusses the operation of the McASP.

22.3.10.1 Data Transmission and Reception

The processor services the McASP by writing data to the XBUF register(s) for transmit operations, and by reading data from the RBUF register(s) for receive operations. The McASP sets status flag and notifies the processor whenever data is ready to be serviced. Section 22.3.10.1.1 discusses data ready status in detail.

The XBUF and RBUF registers can be accessed through one of the two peripheral ports of the device:

- The data port (DAT): This port is dedicated for data transfers on the device.
- The configuration bus (CFG): This port is used for both data transfers and peripheral configuration control on the device.

Section 22.3.10.1.2 and Section 22.3.10.1.3 discuss how to perform transfers through the data port and the configuration bus.

Either the CPU or the DMA can be used to service the McASP through any of these two peripheral ports. The CPU and DMA usages are discussed in Section 22.3.10.1.4 and Section 22.3.14.2.

22.3.10.1.1 Data Ready Status and Event/Interrupt Generation

22.3.10.1.1.1 Transmit Data Ready

The transmit data ready flag XDATA bit in the XSTAT register reflects the status of the XBUF register. The XDATA flag is set when data is transferred from the XRBUF[n] buffers to the XRSR[n] shift registers, indicating that the XBUF is empty and ready to accept new data from the processor. This flag is cleared when the XDATA bit is written with a 1, or when all the serializers configured as transmitters are written by the processor.

Whenever XDATA is set, an DMA event AXEVT is automatically generated to notify the DMA of the XBUF empty status. An interrupt AXINT is also generated if XDATA interrupt is enabled in the XINTCTL register (See Section 22.3.13.2 for details).

For DMA requests, the McASP does not require XSTAT to be read between DMA events. This means that even if XSTAT already has the XDATA flag set to 1 from a previous request, the next transfer triggers another DMA request.

Since all serializers act in lockstep, only one DMA event is generated to indicate that all active transmit serializers are ready to be written to with new data.

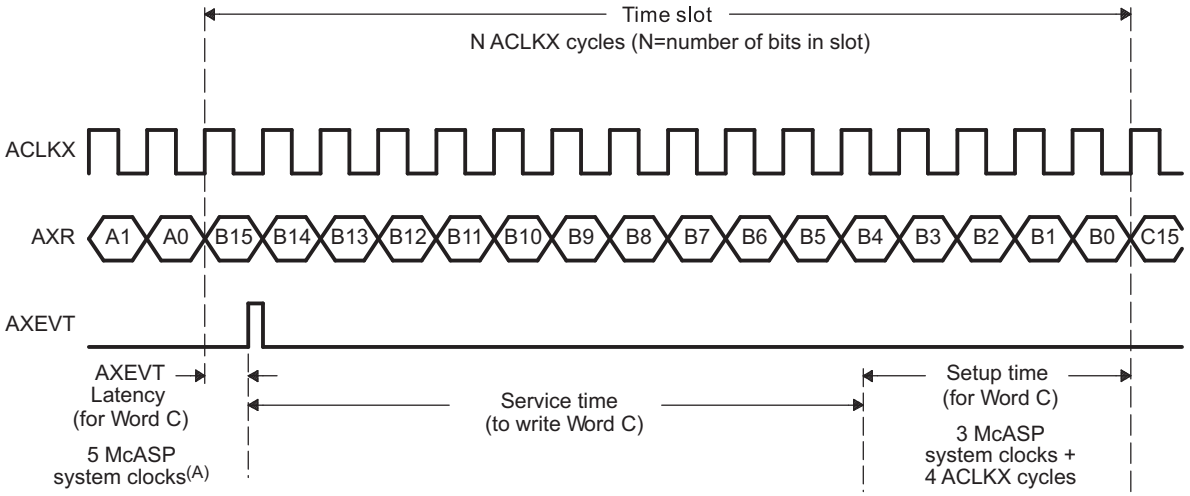
Figure 22-26 shows the timing details of when AXEVT is generated at the McASP boundary. In this example, as soon as the last bit (bit A0) of Word A is transmitted, the McASP sets the XDATA flag and generates an AXEVT event. However, it takes up to 5 McASP system clocks (AXEVT Latency) before AXEVT is active at the McASP boundary. Upon AXEVT, the processor can begin servicing the McASP by writing Word C into the XBUF (Processor Service Time). The processor must write Word C into the XBUF no later than the setup time required by the McASP (Setup Time).

The maximum Processor Service Time (Figure 22-26) can be calculated as:

Processor Service Time = Time Slot - AXEVT Latency - Setup Time

Copyright © 2011, Texas Instruments Incorporated

Figure 22-26. Processor Service Time Upon Transmit DMA Event (AXEVT)



A Refer to the device-specific data manual for the McASP system clock source. This is not the same as AUXCLK.

Example 22-1. Processor Service Time Calculation for Transmit DMA Event (AXEVT)

The following is an example to show how to calculate Processor Service Time. Assume the following setup:

- Device: C64x+ DSP at 300 MHz.
- McASP transmits in I2S format at 192 kHz frame rate. Assume slot size is 32 bit.

With the above setup, we obtain the following parameters corresponding to Figure 22-26:

- Calculation of McASP system clock cycle:
  - C64x+ DSP uses SYSCLK2 as the McASP system clock. It runs at 150 MHz (half of device frequency).
  - Therefore, McASP system clock cycle = 1/150 MHz = 6.7 ns.
- Calculation of ACLKX clock cycle:
  - This example has two 32-bit slots per frame, for a total of 64 bits per frame.
  - ACLKX clock cycle is (1/192 kHz)/64 = 81.4 ns.
- Time Slot between AXEVT events:
  - For I2S format, McASP generates two AXEVT events per 192 kHz frame.
  - Therefore, Time Slot between AXEVT events is (1/192 kHz)/2 = 2604 ns.
- AXEVT Latency:
  = 5 McASP system clocks
  = 6.7 ns × 5 = 33.5 ns
- Setup Time
  = 3 McASP system clocks + 4 ACLKX cycles
  = (6.7 ns × 3) + (81.4 ns × 4)
  = 345.7 ns
- Processor Service Time
  = Time Slot - AXEVT Latency - Setup Time
  = 2604 ns - 33.5 ns - 345.7 ns
  = 2225 ns

22.3.10.1.1.2 Receive Data Ready

Similarly, the receive data ready flag RDATA bit in the RSTAT reflects the status of the RBUF register. The RDATA flag is set when data is transferred from the XRSR[n] shift registers to the XRBUF[n] buffers, indicating that the RBUF contains received data and is ready to have the processor read the data. This flag is cleared when the RDATA bit is written with a 1, or when all the serializers configured as receivers are read.

Whenever RDATA is set, an DMA event AREVT is automatically generated to notify the DMA of the RBUF ready status. An interrupt ARINT is also generated if RDATA interrupt is enabled in the RINTCTL register (See Section 22.3.13.3 for details).

For DMA requests, the McASP does not require RSTAT to be read between DMA events. This means that even if RSTAT already has the RDATA flag set to 1 from a previous request, the next transfer triggers another DMA request.

Since all serializers act in lockstep, only one DMA event is generated to indicate that all active receive serializers are ready to receive new data.

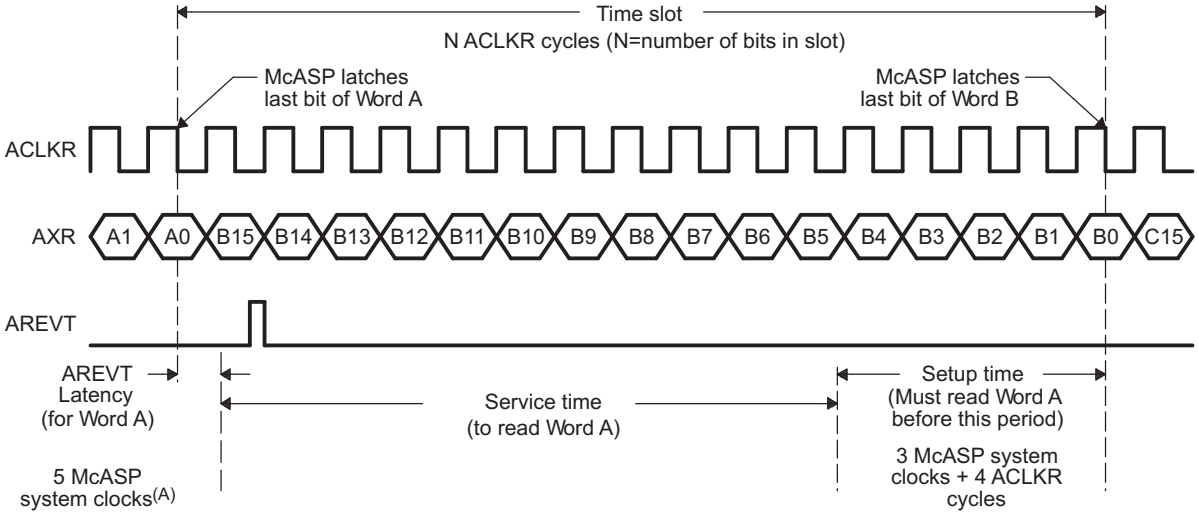
Figure 22-27 shows the timing details of when AREVT is generated at the McASP boundary. In this example, as soon as the last bit (bit A0) of Word A is received, the McASP sets the RDATA flag and generates an AREVT event. However, it takes up to 5 McASP system clocks (AREVT Latency) before AREVT is active at the McASP boundary. Upon AREVT, the processor can begin servicing the McASP by reading Word A from the RBUF (Processor Service Time). The processor must read Word A from the XBUF no later than the setup time required by the McASP (Setup Time).

The maximum Processor Service Time (Figure 22-27) can be calculated as:

Processor Service Time = Time Slot - AREVT Latency - Setup Time

The Processor Service Time calculation for receive is similar to the calculation for transmit. See Example 22-1 for Processor Service Time calculation using transmit as an example.

Figure 22-27. Processor Service Time Upon Receive DMA Event (AREVT)



A The device uses SYSCLK2 as the McASP system clock source.

22.3.10.1.2 Transfers Through the Data Port (DAT)

NOTE: To perform internal transfers through the data port, clear XBUSEL/RBUSEL bit to 0 in the respective XFMT/RFMT registers. Failure to do so will result in software malfunction.

Typically, you will access the McASP XRBUF registers through the data port. To access through the data port, simply have the CPU or DMA access the XRBUF through its data port location. Through the data port, the DMA/CPU can service all the serializers through a single address. The McASP automatically cycles through the appropriate serializers.

For transmit operations through the data port, the DMA/CPU should write to the same XBUF data port address to service all of the active transmit serializers. In addition, the DMA/CPU should write to the XBUF for all active transmit serializers in incremental (although not necessarily consecutive) order. For example, if serializers 0, 4, and 5, are set up as active transmitters, the DMA/CPU should write to the XBUF data port address four times with data for serializers 0, 4, and 5, upon each transmit data ready event. This exact servicing order must be followed so that data appears in the appropriate serializers.

Similarly, for receive operations through the data port, the DMA/CPU should read from the same RBUF data port address to service all of the active receive serializers. In addition, reads from the active receive serializers through the data port return data in incremental (although not necessarily consecutive) order. For example, if serializers 1, 2, and 3, are set up as active receivers, the DMA/CPU should read from the RBUF data port address four times to obtain data for serializers 1, 2, and 3, in this exact order, upon each receive data ready event.

When transmitting, the DMA/CPU must write data to each serializer configured as "active" and "transmit" within each time slot. Failure to do so results in a buffer underrun condition (Section 22.3.10.4.2). Similarly, when receiving, data must be read from each serializer configured as "active" and "receive" within each time slot. Failure to do results in a buffer overrun condition (Section 22.3.10.4.3).

To perform internal transfers through the data port, clear XBUSEL/RBUSEL bit to 0 in the respective XFMT/RFMT registers.

22.3.10.1.3 Transfers Through the Configuration Bus (CFG)

NOTE: To perform internal transfers through the configuration bus, set XBUSEL/RBUSEL bit to 1 in the respective XFMT/RFMT registers. Failure to do so will result in software malfunction.

In this method, the DMA/CPU accesses the XRBUF registers through the configuration bus address. The exact XRBUF register address for any particular serializer is determined by adding the offset for that particular serializer to the base address for the particular McASP. XRBUF for the serializers configured as transmitters is given the name XBUF*n*. For example, the XRBUF associated with transmit serializer 2 is named XBUF2. Similarly, XRBUF for the serializers configured as receivers is given the name RBUF*n*.

Accessing the XRBUF registers through the data port is different because the CPU/DMA only needs to access one single address. When accessing through the configuration bus, the CPU/DMA must provide the exact XBUF*n* or RBUF*n* address for each access.

When transmitting, DMA/CPU must write data to each serializer configured as "active" and "transmit" within each time slot. Failure to do so results in a buffer underrun condition (Section 22.3.10.4.2). Similarly when receiving, data must be read from each serializer configured as "active" and "receive" within each time slot. Failure to do results in a buffer overrun condition (Section 22.3.10.4.3).

To perform internal transfers through the configuration bus, set XBUSEL/RBUSEL bit to 1 in the respective XFMT/RFMT registers.

22.3.10.1.4 Using the CPU for McASP Servicing

The CPU can be used to service the McASP through interrupt (upon AXINT/ARINT interrupts) or through polling the XDATA bit in the XSTAT register. As discussed in Section 22.3.10.1.2 and Section 22.3.10.1.3, the CPU can access through either the data port or through the configuration bus.

Copyright © 2011, Texas Instruments Incorporated

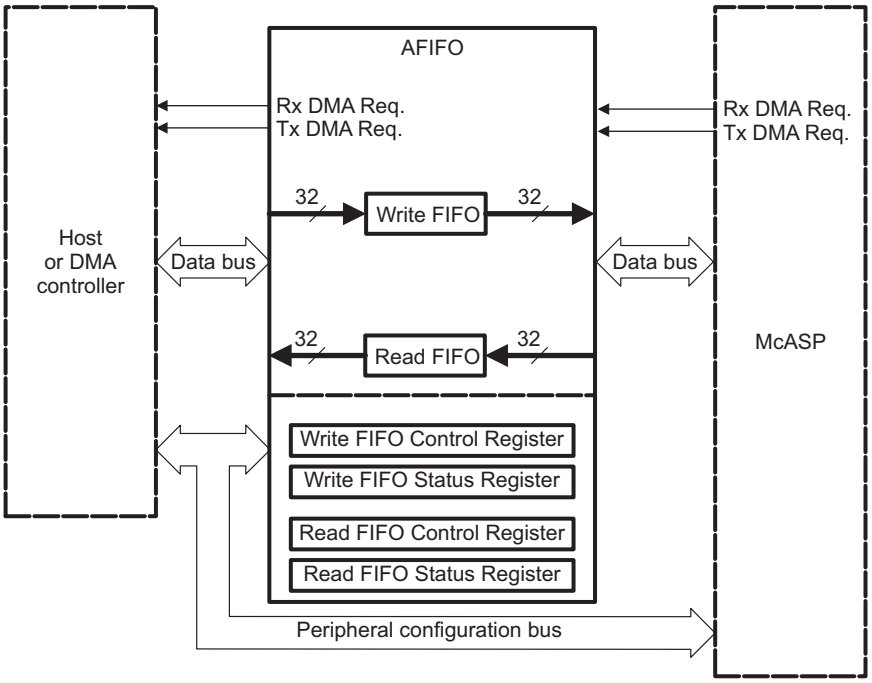
To use the CPU to service the McASP through interrupts, the XDATA/RDATA bit must be enabled in the respective XINTCTL/RINTCTL registers, to generate interrupts AXINT/ARINT to the CPU upon data ready.

22.3.10.2 McASP Audio FIFO (AFIFO)

The AFIFO contains two FIFOs: one Read FIFO (RFIFO), and one Write FIFO (WFIFO). To ensure backward compatibility with existing software, both the Read and Write FIFOs are disabled by default. See Figure 22-28 for a high-level block diagram of the AFIFO.

The AFIFO may be enabled/disabled and configured via the WFIFOCTL and RFIFOCTL registers. Note that if the Read or Write FIFO is to be enabled, it must be enabled prior to initializing the receive/transmit section of the McASP (see Section 22.3.12.2 for details).

Figure 22-28. McASP Audio FIFO (AFIFO) Block Diagram



22.3.10.2.1 AFIFO Data Transmission

When the Write FIFO is disabled, transmit DMA requests pass through directly from the McASP to the host/DMA controller. Whether the WFIFO is enabled or disabled, the McASP generates transmit DMA requests as needed; the AFIFO is “invisible” to the McASP.

When the Write FIFO is enabled, transmit DMA requests from the McASP are sent to the AFIFO, which in turn generates transmit DMA requests to the host/DMA controller.

If the Write FIFO is enabled, upon a transmit DMA request from the McASP, the WFIFO writes *WNUMDMA* 32-bit words to the McASP if and when there are at least *WNUMDMA* words in the Write FIFO. If there are not, the WFIFO waits until this condition has been satisfied. At that point, it writes *WNUMDMA* words to the McASP. (See description for WFIFOCTL.WNUMDMA in Section 22.4.1.43.)

If the host CPU writes to the Write FIFO, independent of a transmit DMA request, the WFIFO will accept host writes until full. After this point, excess data will be discarded.

Note that when the WFIFO is first enabled, it will immediately issue a transmit DMA request to the host. This is because it begins in an empty state, and is therefore ready to accept data.

Copyright © 2011, Texas Instruments Incorporated

22.3.10.2.1.1 Transmit DMA Event Pacer

The AFIFO may be configured to delay making a transmit DMA request to the host until the Write FIFO has enough space for a specified number of words. In this situation, the number of transmit DMA requests to the host or DMA controller is reduced.

If the Write FIFO has space to accept *WNUMEVT* 32-bit words, it generates a transmit DMA request to the host and then waits for a response. Once *WNUMEVT* words have been written to the FIFO, it checks again to see if there is space for *WNUMEVT* 32-bit words. If there is space, it generates another transmit DMA request to the host, and so on. In this fashion, the Write FIFO will attempt to stay filled.

Note that if transmit DMA event pacing is desired, WFIFOCTL.WNUMEVT should be set to a non-zero integer multiple of the value in WFIFOCTL.WNUMDMA. If transmit DMA event pacing is not desired, then the value in WFIFOCTL.WNUMEVT should be set equal to the value in WFIFOCTL.WNUMDMA.

22.3.10.2.2 AFIFO Data Reception

When the Read FIFO is disabled, receive DMA requests pass through directly from McASP to the host/DMA controller. Whether the RFIFO is enabled or disabled, the McASP generates receive DMA requests as needed; the AFIFO is “invisible” to the McASP.

When the Read FIFO is enabled, receive DMA requests from the McASP are sent to the AFIFO, which in turn generates receive DMA requests to the host/DMA controller.

If the Read FIFO is enabled and the McASP makes a receive DMA request, the RFIFO reads *RNUMDMA* 32-bit words from the McASP, if and when the RFIFO has space for *RNUMDMA* words. If it does not, the RFIFO waits until this condition has been satisfied; at that point, it reads *RNUMDMA* words from the McASP. (See description for RFIFOCTL.RNUMDMA in Section 22.4.1.45.)

If the host CPU reads the Read FIFO, independent of a receive DMA request, and the RFIFO at that time contains less than *RNUMEVT* words, those words will be read correctly, emptying the FIFO.

22.3.10.2.2.1 Receive DMA Event Pacer

The AFIFO may be configured to delay making a receive DMA request to the host until the Read FIFO contains a specified number of words. In this situation, the number of receive DMA requests to the host or DMA controller is reduced.

If the Read FIFO contains at least *RNUMEVT* 32-bit words, it generates a receive DMA request to the host and then waits for a response. Once *RNUMEVT* 32-bit words have been read from the RFIFO, the RFIFO checks again to see if it contains at least another *RNUMEVT* words. If it does, it generates another receive DMA request to the host, and so on. In this fashion, the Read FIFO will attempt to stay empty.

Note that if receive DMA event pacing is desired, RFIFOCTL.RNUMEVT should be set to a non-zero integer multiple of the value in RFIFOCTL.RNUMDMA. If receive DMA event pacing is not desired, then the value in RFIFOCTL.RNUMEVT should be set equal to the value in RFIFOCTL.RNUMDMA.

22.3.10.2.3 Arbitration Between Transmit and Receive DMA Requests

If both the WFIFO and the RFIFO are enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the transmit DMA request. Once a transfer is in progress, it is allowed to complete.

If only the WFIFO is enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the transmit DMA request. Once a transfer is in progress, it is allowed to complete.

If only the RFIFO is enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the receive DMA request. Once a transfer is in progress, it is allowed to complete.

22.3.10.3 Formatter

22.3.10.3.1 Transmit Bit Stream Data Alignment

The McASP transmitter supports serial formats of:

- Slot (or Time slot) size = 8, 12, 16, 20, 24, 28, 32 bits.
- Word size ≤ Slot size.
- Alignment: when more bits/slot than bits/words, then:
  - Left aligned = word shifted first, remaining bits are pad.
  - Right aligned = pad bits are shifted first, word occupies the last bits in slot.
- Order: order of bits shifted out:
  - MSB: most-significant bit of word is shifted out first, last bit is LSB.
  - LSB: least-significant bit of word is shifted out last, last bit is MSB.

Hardware support for these serial formats comes from the programmable options in the transmit bitstream format register (XFMT):

- XRVRS: bit reverse (1) or no bit reverse (0).
- XROT: rotate right by 0, 4, 8, 12, 16, 20, 24, or 28 bits.
- XSSZ: transmit slot size of 8, 12, 16, 20, 24, 28, or 32 bits.

XSSZ should always be programmed to match the slot size of the serial stream. The word size is not directly programmed into the McASP, but rather is used to determine the rotation needed in the XROT field.

Table 22-8 and Figure 22-29 show the XRVRS and XROT fields for each serial format and for both integer and Q31 fractional internal representations.

This discussion assumes that all slot size (SLOT in Table 22-8) and word size (WORD in Table 22-8) options are multiples of 4, since the transmit rotate right unit only supports rotation by multiples of 4. However, the bit mask/pad unit does allow for any number of significant digits. For example, a Q31 number may have 19 significant digits (word) and be transmitted in a 24-bit slot; this would be formatted as a word size of 20 bits and a slot size of 24 bits. However, it is possible to set the bit mask unit to only pass the 19 most-significant digits (program the mask value to FFFF E000h). The digits that are not significant can be set to a selected pad value, which can be any one of the significant digits, a fixed value of 0, or a fixed value of 1.

The transmit bit mask/pad unit operates on data as an initial step of the transmit format unit (see Figure 22-24), and the data is aligned in the same representation as it is written to the transmitter by the processor (typically Q31 or integer).

Table 22-8. Transmit Bitstream Data Alignment

Figure 22-29	Bit Stream Order	Bit Stream Alignment	Internal Numeric Representation	XFMT Bit	
				XROT [1]	XRVRS
(a)[2]	MSB first	Left aligned	Q31 fraction	0	1
(b)	MSB first	Right aligned	Q31 fraction	SLOT - WORD	1
(c)	LSB first	Left aligned	Q31 fraction	32 - WORD	0
(d)	LSB first	Right aligned	Q31 fraction	32 - SLOT	0
(e)[2]	MSB first	Left aligned	Integer	WORD	1
(f)	MSB first	Right aligned	Integer	SLOT	1
(g)	LSB first	Left aligned	Integer	0	0
(h)	LSB first	Right aligned	Integer	(32 - (SLOT - WORD)) % 32	0

(1) WORD = Word size rounded up to the nearest multiple of 4; SLOT = slot size; % = modulo operator
(2) To transmit in I2S format, use MSB first, left aligned, and also select XDATDLY = 01 (1 bit delay)

22.3.10.3.2 Receive Bit Stream Data Alignment

The McASP receiver supports serial formats of:

- Slot or time slot size = 8, 12, 16, 20, 24, 28, 32 bits.
- Word size ≤ Slot size.
- Alignment when more bits/slot than bits/words, then:
  - Left aligned = word shifted first, remaining bits are pad.
  - Right aligned = pad bits are shifted first, word occupies the last bits in slot.
- Order of bits shifted out:
  - MSB: most-significant bit of word is shifted out first, last bit is LSB.
  - LSB: least-significant bit of word is shifted out last, last bit is MSB.

Hardware support for these serial formats comes from the programmable options in the receive bitstream format register (RFMT):

- RRVRS: bit reverse (1) or no bit reverse (0).
- RROT: rotate right by 0, 4, 8, 12, 16, 20, 24, or 28 bits.
- RSSZ: receive slot size of 8, 12, 16, 20, 24, 28, or 32 bits.

RSSZ should always be programmed to match the slot size of the serial stream. The word size is not directly programmed into the McASP, but rather is used to determine the rotation needed in the RROT field.

Table 22-9 and Figure 22-30 show the RRVRS and RROT fields for each serial format and for both integer and Q31 fractional internal representations.

This discussion assumes that all slot size and word size options are multiples of 4; since the receive rotate right unit only supports rotation by multiples of 4. However, the bit mask/pad unit does allow for any number of significant digits. For example, a Q31 number may have 19 significant digits (word) and be transmitted in a 24-bit slot; this would be formatted as a word size of 20 bits and a slot size of 24 bits. However, it is possible to set the bit mask unit to only pass the 19 most-significant digits (program the mask value to FFFF E000h). The digits that are not significant can be set to a selected pad value, which can be any one of the significant digits, a fixed value of 0, or a fixed value of 1.

The receive bit mask/pad unit operates on data as the final step of the receive format unit (see Figure 22-23), and the data is aligned in the same representation as it is read from the receiver by the processor (typically Q31 or integer).

Table 22-9. Receive Bitstream Data Alignment

Figure 22-30	Bit Stream Order	Bit Stream Alignment	Internal Numeric Representation	RFMT Bit	
				RROT [1]	RRVRS
(a)[2]	MSB first	Left aligned	Q31 fraction	SLOT	1
(b)	MSB first	Right aligned	Q31 fraction	WORD	1
(c)	LSB first	Left aligned	Q31 fraction	(32 - (SLOT - WORD)) % 32	0
(d)	LSB first	Right aligned	Q31 fraction	0	0
(e)[2]	MSB first	Left aligned	Integer	SLOT - WORD	1
(f)	MSB first	Right aligned	Integer	0	1
(g)	LSB first	Left aligned	Integer	32 - SLOT	0
(h)	LSB first	Right aligned	Integer	32 - WORD	0

(1) WORD = Word size rounded up to the nearest multiple of 4; SLOT = slot size; % = modulo operator
(2) To transmit in I2S format, select MSB first, left aligned, and also select RDATDLY = 01 (1 bit delay)

22.3.10.4 Error Handling and Management

To support the design of a robust audio system, the McASP includes error-checking capability for the serial protocol, data underrun, and data overrun. In addition, the McASP includes a timer that continually measures the high-frequency master clock every 32 AHCLKX/AHCLKR clock cycles. The timer value can be read to get a measurement of the clock frequency and has a minimum and maximum range setting that can set an error flag if the master clock goes out of a specified range.

Upon the detection of any one or more errors (software selectable), or the assertion of the AMUTEIN input pin, the AMUTE output pin may be asserted to a high or low level to immediately mute the audio output. In addition, an interrupt may be generated if desired, based on any one or more of the error sources.

22.3.10.4.1 Unexpected Frame Sync Error

An unexpected frame sync occurs when:

- In burst mode, when the next active edge of the frame sync occurs early such that the current slot will not be completed by the time the next slot is scheduled to begin.
- In TDM mode, a further constraint is that the frame sync must occur exactly during the correct bit clock (not a cycle earlier or later) and only before slot 0. An unexpected frame sync occurs if this condition is not met.

When an unexpected frame sync occurs, there are two possible actions depending upon when the unexpected frame sync occurs:

1. Early: An early unexpected frame sync occurs when the McASP is in the process of completing the current frame and a new frame sync is detected (not including overlap that occurs due to a 1 or 2 bit frame sync delay). When an early unexpected frame sync occurs:
   - Error interrupt flag is set (XSYNCERR, if an unexpected transmit frame sync occurs; RSYNCERR, if an unexpected receive frame sync occurs).
   - Current frame is not resynchronized. The number of bits in the current frame is completed. The next frame sync, which occurs after the current frame is completed, will be resynchronized.
2. Late: A late unexpected frame sync occurs when there is a gap or delay between the last bit of the previous frame and the first bit of the next frame. When a late unexpected frame sync occurs (as soon as the gap is detected):
   - Error interrupt flag is set (XSYNCERR, if an unexpected transmit frame sync occurs; RSYNCERR, if an unexpected receive frame sync occurs).
   - Resynchronization occurs upon the arrival of the next frame sync.

Late frame sync is detected the same way in both burst mode and TDM mode; however, in burst mode, late frame sync is not meaningful and its interrupt enable should not be set.

22.3.10.4.2 Buffer Underrun Error - Transmitter

A buffer underrun can only occur for serializers programmed to be transmitters. A buffer underrun occurs when the serializer is instructed by the transmit state machine to transfer data from XRBUF[n] to XRSR[n], but XRBUF[n] has not yet been written with new data since the last time the transfer occurred. When this occurs, the transmit state machine sets the XUNDRN flag.

An underrun is checked only once per time slot. The XUNDRN flag is set when an underrun condition occurs. Once set, the XUNDRN flag remains set until the processor explicitly writes a 1 to the XUNDRN bit to clear the XUNDRN bit.

In DIT mode, a pair of BMC zeros is shifted out when an underrun occurs (four bit times at 128 × fs). By shifting out a pair of zeros, a clock may be recovered on the receiver. To recover, reset the McASP and start again with the proper initialization.

In TDM mode, during an underrun case, a long stream of zeros are shifted out causing the DACs to mute. To recover, reset the McASP and start again with the proper initialization.

Copyright © 2011, Texas Instruments Incorporated

22.3.10.4.3 Buffer Overrun Error - Receiver

A buffer overrun can only occur for serializers programmed to be receivers. A buffer overrun occurs when the serializer is instructed to transfer data from XRSR[n] to XRBUF[n], but XRBUF[n] has not yet been read by either the DMA or the processor. When this occurs, the receiver state machine sets the ROVRN flag. However, the individual serializer writes over the data in the XRBUF[n] register (destroying the previous sample) and continues shifting.

An overrun is checked only once per time slot. The ROVRN flag is set when an overrun condition occurs. It is possible that an overrun occurs on one time slot but then the processor catches up and does not cause an overrun on the following time slots. However, once the ROVRN flag is set, it remains set until the processor explicitly writes a 1 to the ROVRN bit to clear the ROVRN bit.

22.3.10.4.4 DMA Error - Transmitter

A transmit DMA error, as indicated by the XDMAERR flag in the XSTAT register, occurs when the DMA (or CPU) writes more words to the DAT port of the McASP than it should. For each DMA event, the DMA should write exactly as many words as there are serializers enabled as transmitters.

XDMAERR indicates that the DMA (or CPU) wrote too many words to the McASP for a given transmit DMA event. Writing too few words results in a transmit underrun error setting XUNDRN in XSTAT.

While XDMAERR occurs infrequently, an occurrence indicates a serious loss of synchronization between the McASP and the DMA or CPU. You should reinitialize both the McASP transmitter and the DMA to resynchronize them.

22.3.10.4.5 DMA Error - Receiver

A receive DMA error, as indicated by the RDMAERR flag in the RSTAT register, occurs when the DMA (or CPU) reads more words from the DAT port of the McASP than it should. For each DMA event, the DMA should read exactly as many words as there are serializers enabled as receivers.

RDMAERR indicates that the DMA (or CPU) read too many words from the McASP for a given receive DMA event. Reading too few words results in a receiver overrun error setting ROVRN in RSTAT.

While RDMAERR occurs infrequently, an occurrence indicates a serious loss of synchronization between the McASP and the DMA or CPU. You should reinitialize both the McASP receiver and the DMA to resynchronize them.

22.3.10.4.6 Clock Failure Detection

22.3.10.4.6.1 Clock-Failure Check Startup

It is expected, initially, that the clock-failure circuits will generate an error until at least one measurement has been taken. Therefore, the clock failure interrupts, clock switch, and mute functions should not immediately be enabled, but be enabled only after a specific startup procedure. The startup procedure is:

1. For the transmit clock failure check:
   (a) Configure transmit clock failure detect logic (XMIN, XMAX, XPS) in the transmit clock check control register (XCLKCHK).
   (b) Clear transmit clock failure flag (XCKFAIL) in the transmit status register (XSTAT).
   (c) Wait until first measurement is taken (> 32 AHCLKX clock periods).
   (d) Verify no clock failure is detected.
   (e) Repeat steps b–d until clock is running and is no longer issuing clock failure errors.
   (f) After the transmit clock is measured and falls within the acceptable range, the following may be enabled:
      (i) transmit clock failure interrupt enable bit (XCKFAIL) in the transmitter interrupt control register (XINTCTL).
      (ii) transmit clock failure detect autoswitch enable bit (XCKFAILSW) in the transmit clock check control register (XCLKCHK).
      (iii) mute option (XCKFAIL) in the mute control register (AMUTE).
2. For the receive clock failure check:
   (a) Configure receive clock failure detect logic (RMIN, RMAX, RPS) in the receive clock check control register (RCLKCHK).
   (b) Clear receive clock failure flag (RCKFAIL) in the receive status register (RSTAT).
   (c) Wait until first measurement is taken (> 32 AHCLKR clock periods).
   (d) Verify no clock failure is detected.
   (e) Repeat steps b–d until clock is running and is no longer issuing clock failure errors.
   (f) After the receive clock is measured and falls within the acceptable range, the following may be enabled:
      (i) receive clock failure interrupt enable bit (RCKFAIL) in the receiver interrupt control register (RINTCTL).
      (ii) mute option (RCKFAIL) in the mute control register (AMUTE).

Copyright © 2011, Texas Instruments Incorporated

22.3.10.4.6.2 Transmit Clock Failure Check and Recovery

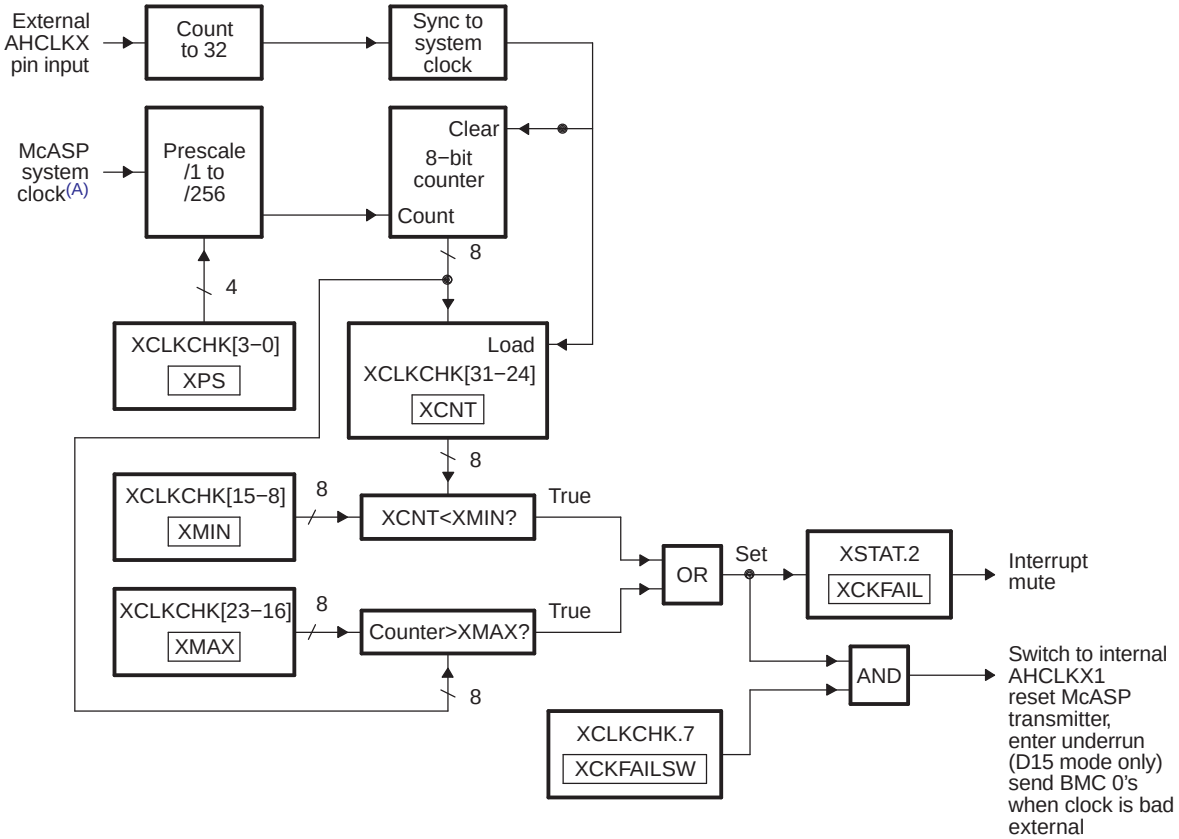
The transmit clock failure check circuit (Figure 22-31) works off both the internal McASP system clock and the external high-frequency serial clock (AHCLKX). It continually counts the number of system clocks for every 32 high rate serial clock (AHCLKX) periods, and stores the count in XCNT of the transmit clock check control register (XCLKCHK) every 32 high rate serial clock cycles.

The logic compares the count against a user-defined minimum allowable boundary (XMIN), and automatically flags an interrupt (XCKFAIL in XSTST) when an out-of-range condition occurs. An out-of-range minimum condition occurs when the count is smaller than XMIN. The logic continually compares the current count (from the running system clock counter) against the maximum allowable boundary (XMAX). This is in case the external clock completely stops, so that the counter value is not copied to XCNT. An out-of-range maximum condition occurs when the count is greater than XMAX. Note that the XMIN and XMAX fields are 8-bit unsigned values, and the comparison is performed using unsigned arithmetic.

An out-of-range count may indicate either that an unstable clock was detected, or that the audio source has changed and a new sample rate is being used.

In order for the transmit clock failure check circuit to operate correctly, the high-frequency serial clock divider must be taken out of reset regardless if AHCLKX is internally generated or externally sourced.

Figure 22-31. Transmit Clock Failure Detection Circuit Block Diagram



A Refer to device data manual for the McASP system clock source. This is not the same as AUXCLK.

Copyright © 2011, Texas Instruments Incorporated

The following actions are taken if a clock failure is detected:

1. Transmit clock failure flag (XCKFAIL) in XSTAT is set. This causes an interrupt if transmit clock failure interrupt enable bit (XCKFAIL) in XINTCTL is set.

In addition (only supported for DIT mode), if the transmit clock failure detect autoswitch enable bit (XCKFAILSW) in XCLKCHK is set, the following additional steps are taken to change the clock source from external to internal:

1. High-frequency transmit clock source bit (HCLKXM) in AHCLKXCTL is set to 1 and internal serial clock divider is selected. However, AHCLKX pin direction does not change to an output while XCKFAIL is set.
2. The internal clock divider is reset, so that the next clock it produces is a full period. However, the transmit clock divide ratio bits (HCLKXDIV) in AHCLKXCTL are not affected, so the internal clock divider generates clocks at the rate configured.
3. The transmit section is reset for a single serial clock period.
4. The transmit section is released from reset and attempts to begin transmitting. If data is available, it begins transmitting immediately; otherwise, it enters the underrun state. An initial underrun is certain to occur, the pattern 1100 (BMC zeroes) should be shifted out initially.

To change back to an external clock, take the following actions:

1. Wait for the external clock to stabilize again. This can be checked by polling the transmit clock count (XCNT) in XCLKCHK.
2. Reset the transmit section according to the startup procedure in Section 22.3.10.4.6.1.

Copyright © 2011, Texas Instruments Incorporated

22.3.10.4.6.3 Receive Clock Failure Check and Recovery

The receive clock failure check circuit (Figure 22-32) works off both the internal McASP system clock and the external high-frequency serial clock (AHCLKR). It continually counts the number of system clocks for every 32 high rate serial clock (AHCLKR) periods, and stores the count in RCNT of the receive clock check control register (RCLKCHK) every 32 high rate serial clock cycles.

The logic compares the count against a user-defined minimum allowable boundary (RMIN) and automatically flags an interrupt (RCKFAIL in RSTAT) when an out-of-range condition occurs. An out-of-range minimum condition occurs when the count is smaller than RMIN. The logic continually compares the current count (from the running system clock counter) against the maximum allowable boundary (RMAX). This is in case the external clock completely stops, so that the counter value is not copied to RCNT. An out-of-range maximum condition occurs when the count is greater than RMAX. Note that the RMIN and RMAX fields are 8-bit unsigned values, and the comparison is performed using unsigned arithmetic.

An out-of-range count may indicate either that an unstable clock was detected or that the audio source has changed and a new sample rate is being used.

In order for the receive clock failure check circuit to operate correctly, the high-frequency serial clock divider must be taken out of reset regardless if AHCLKR is internally generated or externally sourced.

22.3.10.5 Loopback Modes

The McASP features a digital loopback mode (DLB) that allows testing of the McASP code in TDM mode with a single processor device. In loopback mode, output of the transmit serializers is connected internally to the input of the receive serializers. Therefore, you can check the receive data against the transmit data to ensure that the McASP settings are correct. Digital loopback mode applies to TDM mode only (2 to 32 slots in a frame). It does not apply to DIT mode (XMOD = 180h) or burst mode (XMOD = 0).

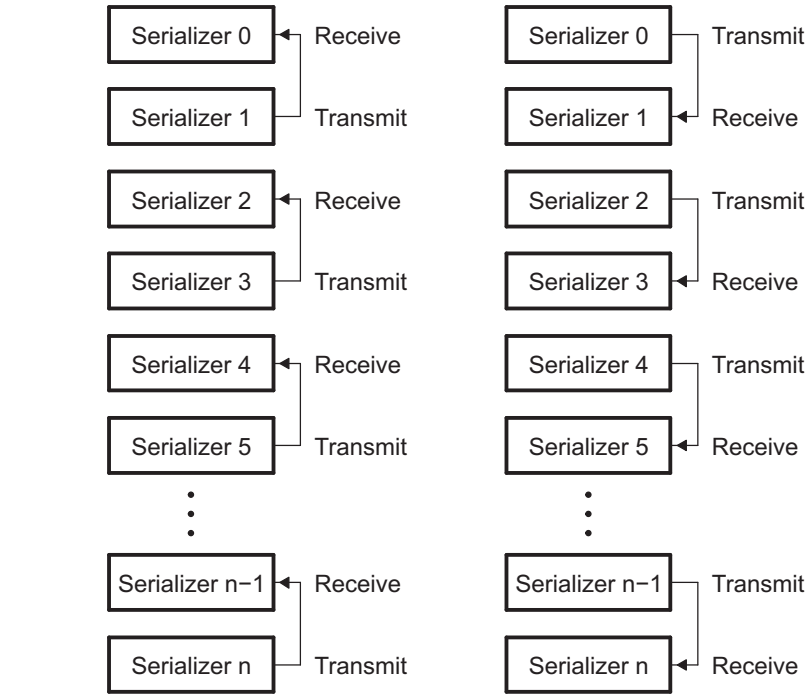
Figure 22-33 shows the basic logical connection of the serializers in loopback mode. Two types of loopback connections are possible, selected by the ORD bit in the digital loopback control register (DLBCTL) as follows:

- ORD = 0: Outputs of odd serializers are connected to inputs of even serializers. If this mode is selected, you should configure odd serializers to be transmitters and even serializers to be receivers.
- ORD = 1: Outputs of even serializers are connected to inputs of odd serializers. If this mode is selected, you should configure even serializers to be transmitters and odd serializers to be receivers.

Data can be externally visible at the I/O pin of the transmit serializer if the pin is configured as a McASP output pin by setting the corresponding PFUNC bit to 0 and PDIR bit to 1.

In loopback mode, the transmit clock and frame sync are used by both the transmit and receive sections of the McASP. The transmit and receive sections operate synchronously. This is achieved by setting the MODE bit of the DLBCTL register to 01b and the ASYNC bit of the ACLKXCTL register to 0.

Figure 22-33. Serializers in Loopback Mode



(a) DLBEN = 1 (loopback enabled) and ORD = 0 (even receive, odd transmit)

(b) DLBEN = 1 (loopback enabled) and ORD = 1 (odd receive, even transmit)

Copyright © 2011, Texas Instruments Incorporated

22.3.10.5.1 Loopback Mode Configurations

This is a summary of the settings required for digital loopback mode for TDM format:

- The DLBEN bit in DLBCTL must be set to 1 to enable loopback mode.
- The MODE bits in DLBCTL must be set to 01b for both the transmit and receive sections to use the transmit clock and frame sync generator.
- The ORD bit in DLBCTL must be programmed appropriately to select odd or even serializers to be transmitters or receivers. The corresponding serializers must be configured accordingly.
- The ASYNC bit in ACLKXCTL must be cleared to 0 to ensure synchronous transmit and receive operations.
- RMOD field in AFSRCTL and XMOD field in AFSXCTL must be set to 2h to 20h to indicate TDM mode. Loopback mode does not apply to DIT or burst mode.

22.3.11 Reset Considerations

The McASP has two reset sources: software reset and hardware reset.

22.3.11.1 Software Reset Considerations

The transmitter and receiver portions of the McASP may be put in reset through the global control register (GBLCTL). Note that a valid serial clock must be supplied to the desired portion of the McASP (transmit and/or receive) in order to assert the software reset bits in GBLCTL. see Section 22.3.12.2for details on how to ensure reset has occurred.

The entire McASP module may also be reset through the Power and Sleep Controller (PSC). Note that from the McASP perspective, this reset appears as a hardware reset to the entire module.

22.3.11.2 Hardware Reset Considerations

When the McASP is reset due to device reset, the entire serial port (including the transmitter and receiver state machines, and other registers) is reset.

22.3.12 Setup and Initialization

This section discusses steps necessary to use the McASP module.

22.3.12.1 Considerations When Using a McASP

The following is a list of things to be considered for systems using a McASP:

22.3.12.1.1 Clocks

For each receive and transmit section:

- External or internal generated bit clock and high frequency clock?
- If internally generated, what is the bit clock speed and the high frequency clock speed?
- Clock polarity?
- External or internal generated frame sync?
- If internally generated, what is frame sync speed?
- Frame sync polarity?
- Frame sync width?
- Transmit and receive sync or asynchronous?

22.3.12.1.2 Data Pins

For each pin of each McASP:

- McASP or GPIO?
- Input or output?

Copyright © 2011, Texas Instruments Incorporated

22.3.12.1.3 Data Format

For each transmit and receive data:

- Internal numeric representation (integer, Q31 fraction)?
- I2S or DIT (transmit only)?
- Time slot delay (0, 1, or 2 bit)?
- Alignment (left or right)?
- Order (MSB first, LSB first)?
- Pad (if yes, pad with what value)?
- Slot size?
- Rotate?
- Mask?

22.3.12.1.4 Data Transfers

- Internal: DMA or CPU?
- External: TDM or burst?
- Bus: configuration bus (CFG) or data port (DAT)?

22.3.12.2 Transmit/Receive Section Initialization

You must follow the following steps to properly configure the McASP. If external clocks are used, they should be present prior to the following initialization steps.

1. Reset McASP to default values by setting GBLCTL = 0.
2. Configure all McASP registers except GBLCTL in the following order:
   (a) Power down and emulation management: PWRDEMU.
   (b) Receive registers: RMASK, RFMT, AFSRCTL, ACLKRCTL, AHCLKRCTL, RTDM, RINTCTL, RCLKCHK. If external clocks AHCLKR and/or ACLKR are used, they must be running already for proper synchronization of the GBLCTL register.
   (c) Transmit registers: XMASK, XFMT, AFSXCTL, ACLKXCTL, AHCLKXCTL, XTDM, XINTCTL, XCLKCHK. If external clocks AHCLKX and/or ACLKX are used, they must be running already for proper synchronization of the GBLCTL register.
   (d) Serializer registers: SRCTL[n].
   (e) Global registers: Registers PFUNC, PDIR, DITCTL, DLBCTL, AMUTE. Note that PDIR should only be programmed after the clocks and frames are set up in the steps above. This is because the moment a clock pin is configured as an output in PDIR, the clock pin starts toggling at the rate defined in the corresponding clock control register. Therefore you must ensure that the clock control register is configured appropriately before you set the pin to be an output. A similar argument applies to the frame sync pins. Also note that the reset state for the transmit high-frequency clock divide register (HCLKXDIV) is divide-by-1, and the divide-by-1 clocks are not gated by the transmit high-frequency clock divider reset enable (XHCLKRST).
   (f) DIT registers: For DIT mode operation, set up registers DITCSRA[n], DITCSRB[n], DITUDRA[n], and DITUDRB[n].
3. Start the respective high-frequency serial clocks AHCLKX and/or AHCLKR. This step is necessary even if external high-frequency serial clocks are used:
   (a) Take the respective internal high-frequency serial clock divider(s) out of reset by setting the RHCLKRST bit for the receiver and/or the XHCLKRST bit for the transmitter in GBLCTL. All other bits in GBLCTL should be held at 0.
   (b) Read back from GBLCTL to ensure the bit(s) to which you wrote are successfully latched in GBLCTL before you proceed.

Copyright © 2011, Texas Instruments Incorporated

4. Start the respective serial clocks ACLKX and/or ACLKR. This step can be skipped if external serial clocks are used and they are running:
   (a) Take the respective internal serial clock divider(s) out of reset by setting the RCLKRST bit for the receiver and/or the XCLKRST bit for the transmitter in GBLCTL. All other bits in GBLCTL should be left at the previous state.
   (b) Read back from GBLCTL to ensure the bit(s) to which you wrote are successfully latched in GBLCTL before you proceed.
5. Setup data acquisition as required:
   (a) If DMA is used to service the McASP, set up data acquisition as desired and start the DMA in this step, before the McASP is taken out of reset.
   (b) If CPU interrupt is used to service the McASP, enable the transmit and/ or receive interrupt as required.
   (c) If CPU polling is used to service the McASP, no action is required in this step.
6. Activate serializers.
   (a) Before starting, clear the respective transmitter and receiver status registers by writing XSTAT = FFFFh and RSTAT = FFFFh.
   (b) Take the respective serializers out of reset by setting the RSRCLR bit for the receiver and/or the XSRCLR bit for the transmitter in GBLCTL. All other bits in GBLCTL should be left at the previous state.
   (c) Read back from GBLCTL to ensure the bit(s) to which you wrote are successfully latched in GBLCTL before you proceed.
7. Verify that all transmit buffers are serviced. Skip this step if the transmitter is not used. Also, skip this step if time slot 0 is selected as inactive (special cases, see Figure 22-21, second waveform). As soon as the transmit serializer is taken out of reset, XDATA in the XSTAT register is set, indicating that XBUF is empty and ready to be serviced. The XDATA status causes an DMA event AXEVT to be generated, and can cause an interrupt AXINT to be generated if it is enabled in the XINTCTL register.
   (a) If DMA is used to service the McASP, the DMA automatically services the McASP upon receiving AXEVT. Before proceeding in this step, you should verify that the XDATA bit in the XSTAT is cleared to 0, indicating that all transmit buffers are already serviced by the DMA.
   (b) If CPU interrupt is used to service the McASP, interrupt service routine is entered upon the AXINT interrupt. The interrupt service routine should service the XBUF registers. Before proceeding in this step, you should verify that the XDATA bit in XSTAT is cleared to 0, indicating that all transmit buffers are already serviced by the CPU.
   (c) If CPU polling is used to service the McASP, the XBUF registers should be written to in this step.
8. Release state machines from reset.
   (a) Take the respective state machine(s) out of reset by setting the RSMRST bit for the receiver and/or the XSMRST bit for the transmitter in GBLCTL. All other bits in GBLCTL should be left at the previous state.
   (b) Read back from GBLCTL to ensure the bit(s) to which you wrote are successfully latched in GBLCTL before you proceed.
9. Release frame sync generators from reset. Note that it is necessary to release the internal frame sync generators from reset, even if an external frame sync is being used, because the frame sync error detection logic is built into the frame sync generator.
   (a) Take the respective frame sync generator(s) out of reset by setting the RFRST bit for the receiver, and/or the XFRST bit for the transmitter in GBLCTL. All other bits in GBLCTL should be left at the previous state.
   (b) Read back from GBLCTL to ensure the bit(s) to which you wrote are successfully latched in GBLCTL before you proceed.
10. Upon the first frame sync signal, McASP transfers begin. The McASP synchronizes to an edge on the frame sync pin, not the level on the frame sync pin. This makes it easy to release the state machine and frame sync generators from reset.
    (a) For example, if you configure the McASP for a rising edge transmit frame sync, then you do not need to wait for a low level on the frame sync pin before releasing the McASP transmitter state

machine and frame sync generators from reset.

22.3.12.3 Separate Transmit and Receive Initialization

In many cases, it is desirable to separately initialize the McASP transmitter and receiver. For example, you may delay the initialization of the transmitter until the type of data coming in on the receiver is recognized. Or a change in the incoming data stream on the receiver may necessitate a reinitialization of the transmitter.

In this case, you may still follow the sequence outlined in Section 22.3.12.2, but use it for each section (transmit, receive) individually. The GBLCTL register is aliased to RGBLCTL and XGBLCTL to facilitate separate initialization of transmit and receive sections.

22.3.12.4 Importance of Reading Back GBLCTL

In Section 22.3.12.2, steps 3b, 4b, 6c, 8b, and 9b state that GBLCTL should be read back until the bits that were written are successfully latched. This is important, because the transmitter and receiver state machines run off of the respective bit clocks, which are typically about tens to hundreds of times slower than the processor's internal bus clock. Therefore, it takes many cycles between when the processor writes to GBLCTL (or RGBLCTL and XGBLCTL), and when the McASP actually recognizes the write operation. If you skip this step, then the McASP may never see the reset bits in the global control registers get asserted and de-asserted; resulting in an uninitialized McASP.

Therefore, the logic in McASP has been implemented such that once the processor writes GBLCTL, RGBLCTL, or XGBLCTL, the resulting write is not visible by reading back GBLCTL until the McASP has recognized the change. This typically requires two bit clocks plus two processor bus clocks to occur.

Also, if the bit clocks can be completely stopped, any software that polls GBLCTL should be implemented with a time-out. If GBLCTL does not have a time-out, and the bit clock stops, the changes written to GBLCTL will not be reflected until the bit clock restarts.

Finally, please note that while RGBLCTL and XGBLCTL allow separate changing of the receive and transmit halves of GBLCTL, they also immediately reflect the updated value (useful for debug purposes). Only GBLCTL can be used for the read back step.

22.3.12.5 Synchronous Transmit and Receive Operation (ASYNC = 0)

When ASYNC = 0 in ACLKXCTL, the transmit and receive sections operate synchronously from the transmit section clock and transmit frame sync signals (Figure 22-17). The receive section may have a different (but compatible in terms of slot size) data format.

When ASYNC = 0, the receive frame sync generator is internally disabled. If the AFSX pin is configured as an output, it serves as the frame sync signal for both transmit and receive. The AFSR pin should not be used because the transmit frame sync generator output, which is used by both the transmitter and the receiver when ASYNC = 0, is not propagated to the AFSR pin (Figure 22-19).

When ASYNC = 0, the transmit and receive sections must share some common settings, since they both use the same clock and frame sync signals:

- DITEN = 0 in DITCTL (TDM mode is enabled).
- The total number of bits per frame must be the same (that is, RSSZ × RMOD must equal XSSZ × XMOD).
- Both transmit and receive should either be specified as burst or TDM mode, but not mixed.
- The settings in ACLKRCTL are irrelevant.
- FSXM must match FSRM.
- FXWID must match FRWID.

For all other settings, the transmit and receive sections may be programmed independently.

22.3.12.6 Asynchronous Transmit and Receive Operation (ASYNC = 1)

When ASYNC = 1 in ACLKXCTL, the transmit and receive sections operate completely independently and have separate clock and frame sync signals (Figure 22-17, Figure 22-18, and Figure 22-19). The events generated by each section come asynchronously.

Copyright © 2011, Texas Instruments Incorporated

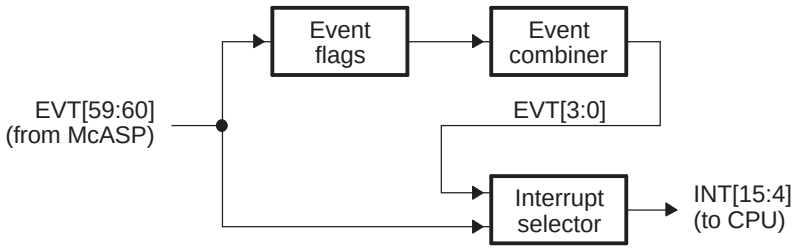
22.3.13 Interrupts

22.3.13.1 Interrupt Multiplexing

The processor includes an interrupt controller (INTC) to manage CPU interrupts. The INTC maps the device events to 12 CPU interrupts. The McASP generates 4 interrupts to the processor.

The event inputs can be routed to 12 maskable interrupts to the CPU (INT[15:4]). The INTC interrupt selector allows the McASP system events to be routed to any of the 12 CPU interrupt inputs. Furthermore, the INTC provides status flags and allows the combination of events, as shown in Figure 22-34. You must properly configure the INTC by enabling, masking, and routing the McASP system events to the desired CPU interrupts.

Figure 22-34. Interrupt Multiplexing



22.3.13.2 Transmit Data Ready Interrupt

The transmit data ready interrupt (XDATA) is generated if XDATA is 1 in the XSTAT register and XDATA is also enabled in XINTCTL. Section 22.3.10.1.1 provides details on when XDATA is set in the XSTAT register.

A transmit start of frame interrupt (XSTAFRM) is triggered by the recognition of transmit frame sync. A transmit last slot interrupt (XLAST) is a qualified version of the data ready interrupt (XDATA). It has the same behavior as the data ready interrupt, but is further qualified by having the data requested belonging to the last slot (the slot that just ended was next-to-last TDM slot, current slot is last slot).

22.3.13.3 Receive Data Ready Interrupt

The receive data ready interrupt (RDATA) is generated if RDATA is 1 in the RSTAT register and RDATA is also enabled in RINTCTL. Section 22.3.10.1.2 provides details on when RDATA is set in the RSTAT register.

A receiver start of frame interrupt (RSTAFRM) is triggered by the recognition of a receiver frame sync. A receiver last slot interrupt (RLAST) is a qualified version of the data ready interrupt (RDATA). It has the same behavior as the data ready interrupt, but is further qualified by having the data in the buffer come from the last TDM time slot (the slot that just ended was last TDM slot).

22.3.13.4 Error Interrupts

Upon detection, the following error conditions generate interrupt flags:

- In the receive status register (RSTAT):
  - Receiver overrun (ROVRN).
  - Unexpected receive frame sync (RSYNCERR).
  - Receive clock failure (RCKFAIL).
  - Receive DMA error (RDMAERR).

Copyright © 2011, Texas Instruments Incorporated

- In the transmit status register (XSTAT):
  - Transmit underrun (XUNDRN).
  - Unexpected transmit frame sync (XSYNCERR).
  - Transmit clock failure (XCKFAIL).
  - Transmit DMA error (XDMAERR).

Each interrupt source also has a corresponding enable bit in the receive interrupt control register (RINTCTL) and transmit interrupt control register (XINTCTL). If the enable bit is set in RINTCTL or XINTCTL, an interrupt is requested when the interrupt flag is set in RSTAT or XSTAT. If the enable bit is not set, no interrupt request is generated. However, the interrupt flag may be polled.

22.3.13.5 Audio Mute (AMUTE) Function

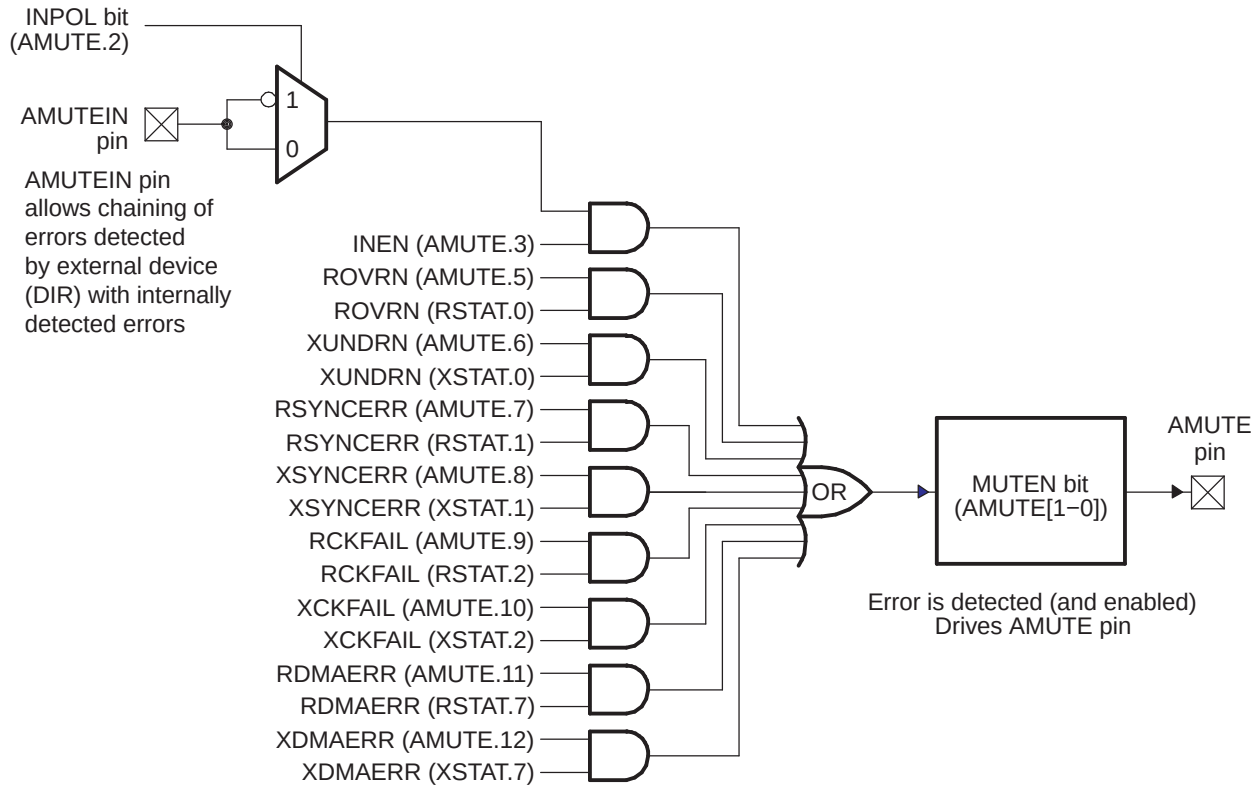
The McASP includes an automatic audio mute function (Figure 22-35) that asserts in hardware the AMUTE pin to a preprogrammed output state, as selected by the MUTEN bit in the audio mute control register (AMUTE). The AMUTE pin is asserted when one of the interrupt flags is set or an external device issues an error signal on the AMUTEIN input. Typically, the AMUTEIN input is shared with a device interrupt pin (for example EXT_INT4).

The AMUTEIN input allows the on-chip logic to consider a mute input from other devices in the system, so that all errors may be considered. The AMUTEIN input has a programmable polarity to allow it to adapt to different devices, as selected by the INPOL bit in AMUTE, and it must be enabled explicitly.

In addition to the external AMUTEIN input, the AMUTE pin output may be asserted when one of the error interrupt flags is set and its mute function is enabled in AMUTE.

When one or more of the errors is detected and enabled, the AMUTE pin is driven to an active state that is selected by MUTEN in AMUTE. The active polarity of the AMUTE pin is programmable by MUTEN (and the inactive polarity is the opposite of the active polarity). The AMUTE pin remains driven active until software clears all the error interrupt flags that are enabled to mute, and until the AMUTEIN is inactive.

Figure 22-35. Audio Mute (AMUTE) Block Diagram



Copyright © 2011, Texas Instruments Incorporated

22.3.13.6 Multiple Interrupts

This only applies to interrupts and not to DMA requests. The following terms are defined:

- **Active Interrupt Request:** a flag in RSTAT or XSTAT is set and the interrupt is enabled in RINTCTL or XINTCTL.
- **Outstanding Interrupt Request:** An interrupt request has been issued on one of the McASP transmit/receive interrupt ports, but that request has not yet been serviced.
- **Serviced:** The CPU writes to RSTAT or XSTAT to clear one or more of the active interrupt request flags.

The first interrupt request to become active for the transmitter with the interrupt flag set in XSTAT and the interrupt enabled in XINTCTL generates a request on the McASP transmit interrupt port AXINT.

If more than one interrupt request becomes active in the same cycle, a single interrupt request is generated on the McASP transmit interrupt port. Subsequent interrupt requests that become active while the first interrupt request is outstanding do not immediately generate a new request pulse on the McASP transmit interrupt port.

The transmit interrupt is serviced with the CPU writing to XSTAT. If any interrupt requests are active after the write, a new request is generated on the McASP transmit interrupt port.

The receiver operates in a similar way, but using RSTAT, RINTCTL, and the McASP receive interrupt port ARINT.

One outstanding interrupt request is allowed on each port, so a transmit and a receive interrupt request may both be outstanding at the same time.

22.3.14 EDMA Event Support

22.3.14.1 EDMA Events

There are 6 EDMA events.

22.3.14.2 Using the DMA for McASP Servicing

The most typical scenario is to use the DMA to service the McASP through the data port, although the DMA can also service the McASP through the configuration bus. Two possibilities exist for using the DMA events to service the McASP:

1. Use **AXEVT/AREVT**: Triggered upon each XDATA/RDATA transition from 0 to 1.
2. Use **AXEVTO/AREVTO** and **AXEVTE/AREVTE**: Alternating AXEVT/AREVT events for odd/even slots. Upon AXEVT/AREVT, AXEVTO/AREVTO is triggered if the event is for an odd channel, and AXEVTE/AREVTE is triggered if the event is for an even channel.

NOTE: Check the device-specific data manual to see if AXEVTO/AREVTO and AXEVTE/AREVTE are supported. These are optional.

Figure 22-36 and Figure 22-37 show an example audio system with six audio channels (LF, RF, LS, RS, C, and LFE) transmitted from three AXRn pins on the McASP. Figure 22-36 and Figure 22-37 show when events AXEVT, AXEVTO, and AXEVTE are triggered. Figure 22-36 and Figure 22-37 also apply for the receive audio channels and show when events AREVT, AREVTO, and AREVTE are triggered.

You can either use the DMA to service the McASP upon events AXEVT and AREVT (Figure 22-36) or upon events AXEVTO, AREVTO, AXEVTE, and AREVTE (Figure 22-37).

Copyright © 2011, Texas Instruments Incorporated

Figure 22-36. DMA Events in an Audio Example–Two Events (Scenario 1)

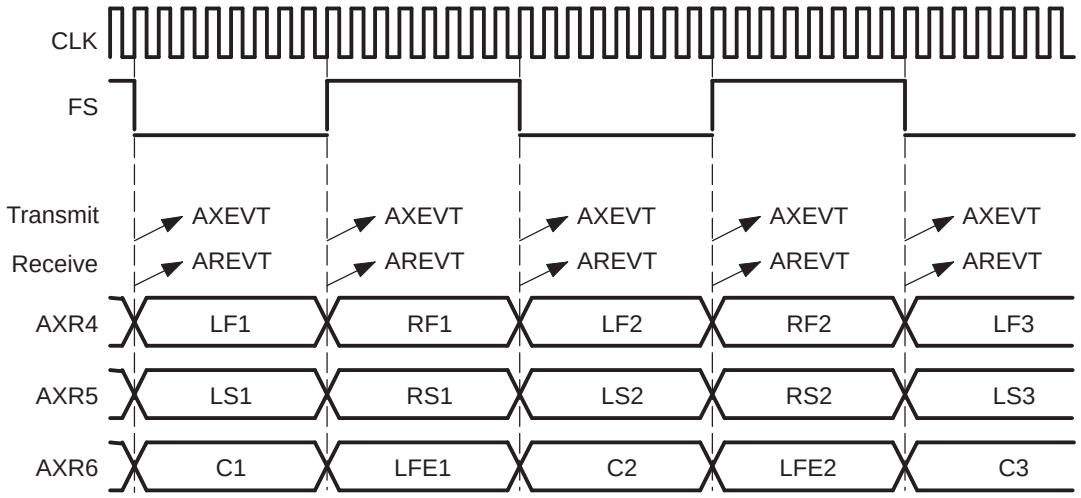


Figure 22-37. DMA Events in an Audio Example–Four Events (Scenario 2)

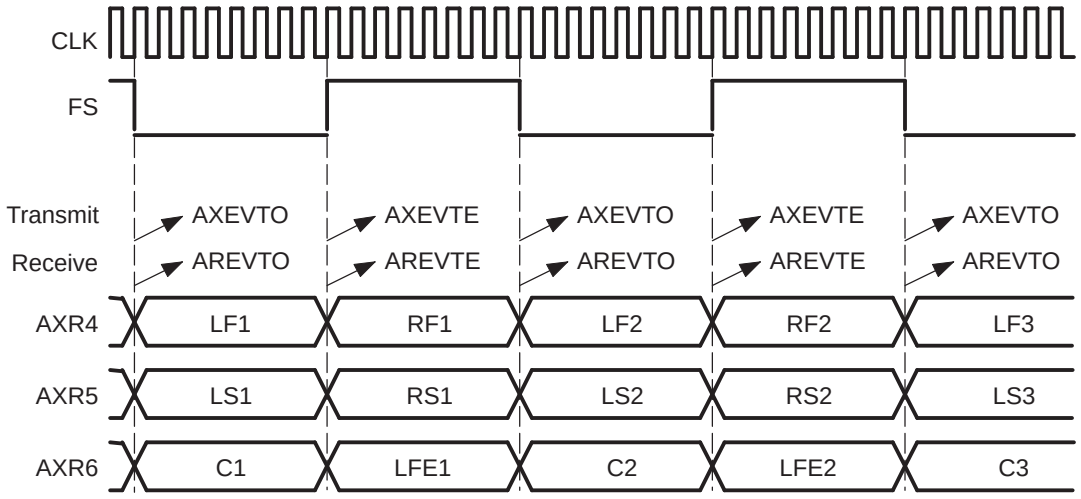


In scenario 1 (Figure 22-36), a DMA event AXEVT/AREVT is triggered on each time slot. In the example, AXEVT is triggered for each of the transmit audio channel time slot (Time slot for channels LF, LS, and C; and time slot for channels RF, RS, LFE). Similarly, AREVT is triggered for each of the receive audio channel time slot. Scenario 1 allows for the use of a single DMA to transmit all audio channels, and a single DMA to receive all audio channels.

In scenario 2 (Figure 22-37), two alternating DMA events are triggered for each time slot. In the example, AXEVTE (even) is triggered for the time slot for the even audio channels (LF, LS, C) and AXEVTO (odd) is triggered for the time slot for the odd audio channels (RF, RS, LFE). AXEVTO and AXEVTE alternate in time. The same is true in the receive direction with the use of AREVTO and AREVTE. This scenario allows for the use of two DMA channels (odd and even) to transmit all audio channels, and two DMA channels to receive all audio channels.

Copyright © 2011, Texas Instruments Incorporated

Here are some guidelines on using the different DMA events:

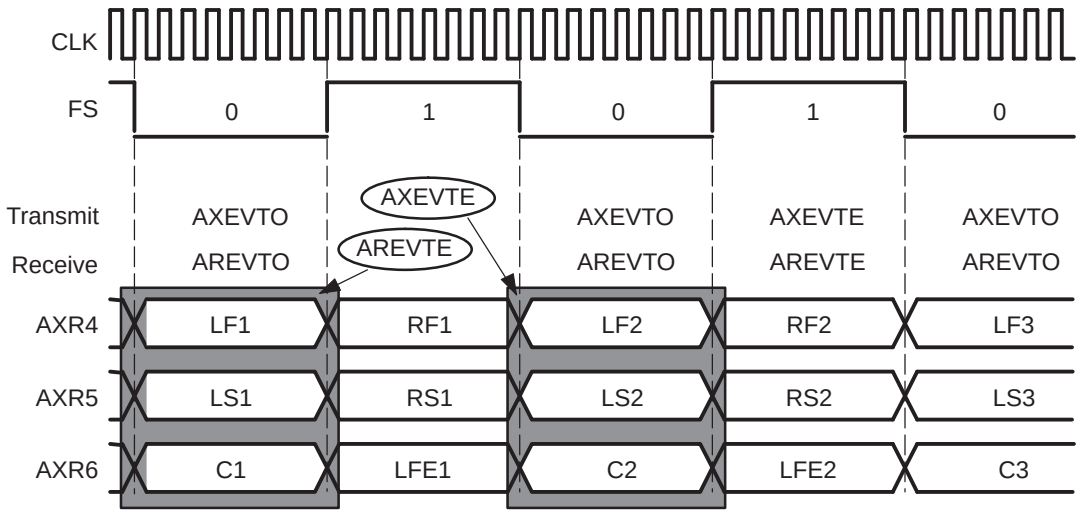
- Either use AXEVT, or the combination of AXEVTO and AXEVTE, to service the McASP. Never use all three at the same time. Similarly for receive, either use AREVT, or the combination of AREVTO and AREVTE.
- The McASP generates transmit DMA events independently from receive DMA events; therefore, separate schemes can be used for transmit and receive DMA. For example, scenario 1 could be used for the transmit data (AXEVT) and scenario 2 could be used for the receive data (AREVTO, AREVTE), and conversely.

Note the difference between DMA event generation and the CPU interrupt generation. DMA events are generated automatically upon data ready; whereas CPU interrupt generation needs to be enabled in the XINTCTL/RINTCTL register.

In Figure 22-37, scenario 2, each transmit DMA request is for data in the next time slot, while each receive DMA request is for data in the previous time slot. For example, Figure 22-38 shows a circled AXEVTE event for an even time slot transmit DMA request. The transmitter always requests a DMA transfer for data it will need to transmit during the next time slot. So, in this example, the circled event AXEVTE is a request for data for samples LF2, LS2, and C2.

On the other hand, the circled AREVTE event is an even time slot receive DMA request. The receiver always requests a DMA transfer for data it received during the previous time slot. In this example, the circled event AREVTE is a request for samples LF1, LS1, and C1.

Figure 22-38. DMA Events in an Audio Example



22.3.15 Power Management

The McASP can be placed in reduced power modes to conserve power during periods of low activity.

22.3.16 Emulation Considerations

NOTE: The receive buffer registers (RBUF*n*) and transmit buffer registers (XBUF*n*) should not be accessed by the emulator when the McASP is running. Such an access will cause the RRDY/XRDY bit in the serializer control register *n* (SRCTL*n*) to be updated.

The McASP does not support the emulation suspend.

Copyright © 2011, Texas Instruments Incorporated

22.4 McASP Registers

22.4.1 McASP CFG Registers

Control registers for the McASP are summarized in Table 22-10. The control registers are accessed through the configuration bus of the device. The receive buffer registers (RBUF*n*) and transmit buffer registers (XBUF*n*) can also be accessed through the data port of the device, as listed in Table 22-52.

Control registers for the McASP Audio FIFO (AFIFO) are summarized in Table 22-11. Note that the AFIFO Write FIFO (WFIFO) and Read FIFO (RFIFO) have independent control and status registers. The AFIFO control registers are accessed through the peripheral configuration port.

Table 22-10. McASP Registers Accessed Through Configuration Bus

Offset	Acronym	Register Description	Section
0h	REV	Revision identification register	Section 22.4.1.1
10h	PFUNC	Pin function register	Section 22.4.1.2

22.4.1.2 Pin Function Register (PFUNC)

The pin function register (PFUNC) specifies the function of AXRn, ACLKX, AHCLKX, AFSX, ACLKR, AHCLKR, and AFSR pins as either a McASP pin or a general-purpose input/output (GPIO) pin. The PFUNC is shown in Figure 22-40 and described in Table 22-13.

CAUTION

Writing to Reserved Bits

Writing a value other than 0 to reserved bits in this register may cause improper device operation.

Table 22-13. Pin Function Register (PFUNC) Field Descriptions

Bit	Field	Value	Description
31	AFSR		Determines if AFSR pin functions as McASP or GPIO.
		0	Pin functions as McASP pin.
		1	Pin functions as GPIO pin.
30	AHCLKR		Determines if AHCLKR pin functions as McASP or GPIO.
		0	Pin functions as McASP pin.
		1	Pin functions as GPIO pin.
29	ACLKR		Determines if ACLKR pin functions as McASP or GPIO.
		0	Pin functions as McASP pin.
		1	Pin functions as GPIO pin.
28	AFSX		Determines if AFSX pin functions as McASP or GPIO.
		0	Pin functions as McASP pin.
		1	Pin functions as GPIO pin.
27	AHCLKX		Determines if AHCLKX pin functions as McASP or GPIO.
		0	Pin functions as McASP pin.
		1	Pin functions as GPIO pin.
26	ACLKX		Determines if ACLKX pin functions as McASP or GPIO.
		0	Pin functions as McASP pin.
		1	Pin functions as GPIO pin.
25	AMUTE		Determines if AMUTE pin functions as McASP or GPIO.
		0	Pin functions as McASP pin.
		1	Pin functions as GPIO pin.
24-6	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
5-0	AXR[5-0]		Determines if AXRn pin functions as McASP or GPIO.
		0	Pin functions as McASP pin.
		1	Pin functions as GPIO pin.

22.4.1.3 Pin Direction Register (PDIR)

The pin direction register (PDIR) specifies the direction of AXRn, ACLKX, AHCLKX, AFSX, ACLKR, AHCLKR, and AFSR pins as either an input or an output pin. The PDIR is shown in Figure 22-41 and described in Table 22-14.

Regardless of the pin function register (PFUNC) setting, each PDIR bit must be set to 1 for the specified pin to be enabled as an output and each PDIR bit must be cleared to 0 for the specified pin to be an input.

For example, if the McASP is configured to use an internally-generated bit clock and the clock is to be driven out to the system, the PFUNC bit must be cleared to 0 (McASP function) and the PDIR bit must be set to 1 (an output).

When AXRn is configured to transmit, the PFUNC bit must be cleared to 0 (McASP function) and the PDIR bit must be set to 1 (an output). Similarly, when AXRn is configured to receive, the PFUNC bit must be cleared to 0 (McASP function) and the PDIR bit must be cleared to 0 (an input).

CAUTION

Writing to Reserved Bits

Writing a value other than 0 to reserved bits in this register may cause improper device operation.

Figure 22-41. Pin Direction Register (PDIR)

22.4.1.4 Pin Data Output Register (PDOUT)

The pin data output register (PDOUT) holds a value for data out at all times, and may be read back at all times. The value held by PDOUT is not affected by writing to PDIR and PFUNC. However, the data value in PDOUT is driven out onto the McASP pin only if the corresponding bit in PFUNC is set to 1 (GPIO function) and the corresponding bit in PDIR is set to 1 (output). When reading data, returns the corresponding bit value in PDOUT[n], does not return input from I/O pin; when writing data, writes to the corresponding PDOUT[n] bit. The PDOUT is shown in Figure 22-42 and described in Table 22-15.

PDOUT has these aliases or alternate addresses:

- PDSET - when written to at this address, writing a 1 to a bit in PDSET sets the corresponding bit in PDOUT to 1; writing a 0 has no effect and keeps the bits in PDOUT unchanged.
- PDCLR - when written to at this address, writing a 1 to a bit in PDCLR clears the corresponding bit in PDOUT to 0; writing a 0 has no effect and keeps the bits in PDOUT unchanged.

There is only one set of data out bits, PDOUT[31-0]. The other registers, PDSET and PDCLR, are just different addresses for the same control bits, with different behaviors during writes.

CAUTION

Writing to Reserved Bits

Writing a value other than 0 to reserved bits in this register may cause improper device operation.

Table 22-15. Pin Data Output Register (PDOUT) Field Descriptions

Bit	Field	Value	Description
31	AFSR		Determines drive on AFSR output pin when the corresponding PFUNC[31] and PDIR[31] bits are set to 1.
		0	Pin drives low.
		1	Pin drives high.
30	AHCLKR		Determines drive on AHCLKR output pin when the corresponding PFUNC[30] and PDIR[30] bits are set to 1.
		0	Pin drives low.
		1	Pin drives high.
29	ACLKR		Determines drive on ACLKR output pin when the corresponding PFUNC[29] and PDIR[29] bits are set to 1.
		0	Pin drives low.
		1	Pin drives high.
28	AFSX		Determines drive on AFSX output pin when the corresponding PFUNC[28] and PDIR[28] bits are set to 1.
		0	Pin drives low.
		1	Pin drives high.
27	AHCLKX		Determines drive on AHCLKX output pin when the corresponding PFUNC[27] and PDIR[27] bits are set to 1.
		0	Pin drives low.
		1	Pin drives high.
26	ACLKX		Determines drive on ACLKX output pin when the corresponding PFUNC[26] and PDIR[26] bits are set to 1.
		0	Pin drives low.
		1	Pin drives high.
25	AMUTE		Determines drive on AMUTE output pin when the corresponding PFUNC[25] and PDIR[25] bits are set to 1.
		0	Pin drives low.
		1	Pin drives high.
24-6	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
5-0	AXR[5-0]		Determines drive on AXR[n] output pin when the corresponding PFUNC[n] and PDIR[n] bits are set to 1.
		0	Pin drives low.
		1	Pin drives high.

Copyright © 2011, Texas Instruments Incorporated

22.4.1.5 Pin Data Input Register (PDIN)

The pin data input register (PDIN) holds the I/O pin state of each of the McASP pins. PDIN allows the actual value of the pin to be read, regardless of the state of PFUNC and PDIR. The value after reset for registers 1 through 15 and 24 through 31 depends on how the pins are being driven. The PDIN is shown in Figure 22-43 and described in Table 22-16.

CAUTION

Writing to Reserved Bits

Writing a value other than 0 to reserved bits in this register may cause improper device operation.

Figure 22-43. Pin Data Input Register (PDIN)

31	30	29	28	27	26	25	24

		0	Pin is logic low.
		1	Pin is logic high.
25	AMUTE		Logic level on AMUTE pin.
		0	Pin is logic low.
		1	Pin is logic high.
24-6	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
5-0	AXR[5-0]		Logic level on AXR[n] pin.
		0	Pin is logic low.
		1	Pin is logic high.

Copyright © 2011, Texas Instruments Incorporated

22.4.1.6 Pin Data Set Register (PDSET)

The pin data set register (PDSET) is an alias of the pin data output register (PDOUT) for writes only. Writing a 1 to the PDSET bit sets the corresponding bit in PDOUT and, if PFUNC = 1 (GPIO function) and PDIR = 1 (output), drives a logic high on the pin. PDSET is useful for a multitasking system because it allows you to set to a logic high only the desired pin(s) within a system without affecting other I/O pins controlled by the same McASP. The PDSET is shown in Figure 22-44 and described in Table 22-17.

CAUTION

Writing to Reserved Bits

Writing a value other than 0 to reserved bits in this register may cause improper device operation.

Figure 22-44. Pin Data Set Register (PDSET)

31	30	29	28	27	26	25	24

Table 22-17. Pin Data Set Register (PDSET) Field Descriptions

Bit	Field	Value	Description
31	AFSR		Allows the corresponding AFSR bit in PDOUT to be set to a logic high without affecting other I/O pins controlled by the same port.
		0	No effect.
		1	PDOUT[31] bit is set to 1.
30	AHCLKR		Allows the corresponding AHCLKR bit in PDOUT to be set to a logic high without affecting other I/O pins controlled by the same port.
		0	No effect.
		1	PDOUT[30] bit is set to 1.
29	ACLKR		Allows the corresponding ACLKR bit in PDOUT to be set to a logic high without affecting other I/O pins controlled by the same port.
		0	No effect.
		1	PDOUT[29] bit is set to 1.
28	AFSX		Allows the corresponding AFSX bit in PDOUT to be set to a logic high without affecting other I/O pins controlled by the same port.
		0	No effect.
		1	PDOUT[28] bit is set to 1.
27	AHCLKX		Allows the corresponding AHCLKX bit in PDOUT to be set to a logic high without affecting other I/O pins controlled by the same port.
		0	No effect.
		1	PDOUT[27] bit is set to 1.
26	ACLKX		Allows the corresponding ACLKX bit in PDOUT to be set to a logic high without affecting other I/O pins controlled by the same port.
		0	No effect.
		1	PDOUT[26] bit is set to 1.
25	AMUTE		Allows the corresponding AMUTE bit in PDOUT to be set to a logic high without affecting other I/O pins controlled by the same port.
		0	No effect.
		1	PDOUT[25] bit is set to 1.
24-6	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
5-0	AXR[5-0]		Allows the corresponding AXR[n] bit in PDOUT to be set to a logic high without affecting other I/O pins controlled by the same port.
		0	No effect.
		1	PDOUT[n] bit is set to 1.

Copyright © 2011, Texas Instruments Incorporated

22.4.1.7 Pin Data Clear Register (PDCLR)

The pin data clear register (PDCLR) is an alias of the pin data output register (PDOUT) for writes only. Writing a 1 to the PDCLR bit clears the corresponding bit in PDOUT and, if PFUNC = 1 (GPIO function) and PDIR = 1 (output), drives a logic low on the pin. PDCLR is useful for a multitasking system because it allows you to clear to a logic low only the desired pin(s) within a system without affecting other I/O pins controlled by the same McASP. The PDCLR is shown in Figure 22-45 and described in Table 22-18.

CAUTION

Writing to Reserved Bits

Writing a value other than 0 to reserved bits in this register may cause improper device operation.

22.4.1.8 Global Control Register (GBLCTL)

The global control register (GBLCTL) provides initialization of the transmit and receive sections. The GBLCTL is shown in Figure 22-46 and described in Table 22-19.

The bit fields in GBLCTL are synchronized and latched by the corresponding clocks (ACLKX for bits 12-8 and ACLKR for bits 4-0). Before GBLCTL is programmed, you must ensure that serial clocks are running. If the corresponding external serial clocks, ACLKX and ACLKR, are not yet running, you should select the internal serial clock source in AHCLKXCTL, AHCLKRCTL, ACLKXCTL, and ACLKRCTL before GBLCTL is programmed. Also, after programming any bits in GBLCTL you should not proceed until you have read back from GBLCTL and verified that the bits are latched in GBLCTL.

Table 22-19. Global Control Register (GBLCTL) Field Descriptions

Bit	Field	Value	Description
31-13	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
12	XFRST		Transmit frame sync generator reset enable bit.
		0	Transmit frame sync generator is reset.
		1	Transmit frame sync generator is active. When released from reset, the transmit frame sync generator begins counting serial clocks and generating frame sync as programmed.
11	XSMRST		Transmit state machine reset enable bit.
		0	Transmit state machine is held in reset. AXRn pin state: If PFUNC[n] = 0 and PDIR[n] = 1; then the serializer drives the AXRn pin to the state specified for inactive time slot (as determined by DISMOD bits in SRCTL).
		1	Transmit state machine is released from reset. When released from reset, the transmit state machine immediately transfers data from XRBUF[n] to XRSR[n]. The transmit state machine sets the underrun flag (XUNDRN) in XSTAT, if XRBUF[n] have not been preloaded with data before reset is released. The transmit state machine also immediately begins detecting frame sync and is ready to transmit. Transmit TDM time slot begins at slot 0 after reset is released.
10	XSRCLR		Transmit serializer clear enable bit. By clearing then setting this bit, the transmit buffer is flushed to an empty state (XDATA = 1). If XSMRST = 1, XSRCLR = 1, XDATA = 1, and XBUF is not loaded with new data before the start of the next active time slot, an underrun will occur.
		0	Transmit serializers are cleared.
		1	Transmit serializers are active. When the transmit serializers are first taken out of reset (XSRCLR changes from 0 to 1), the transmit data ready bit (XDATA) in XSTAT is set to indicate XBUF is ready to be written.
9	XHCLKRST		Transmit high-frequency clock divider reset enable bit.
		0	Transmit high-frequency clock divider is held in reset and passes through its input as divide-by-1..
		1	Transmit high-frequency clock divider is running.
8	XCLKRST		Transmit clock divider reset enable bit.
		0	Transmit clock divider is held in reset. When the clock divider is in reset, it passes through a divide-by-1 of its input.
		1	Transmit clock divider is running.

Table 22-19. Global Control Register (GBLCTL) Field Descriptions (continued)

Bit	Field	Value	Description
7-5	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
4	RFRST		Receive frame sync generator reset enable bit.
		0	Receive frame sync generator is reset.
		1	Receive frame sync generator is active. When released from reset, the receive frame sync generator begins counting serial clocks and generating frame sync as programmed.
3	RSMRST		Receive state machine reset enable bit.
		0	Receive state machine is held in reset.
		1	Receive state machine is released from reset. When released from reset, the receive state machine immediately begins detecting frame sync and is ready to receive. Receive TDM time slot begins at slot 0 after reset is released.
2	RSRCLR		Receive serializer clear enable bit. By clearing then setting this bit, the receive buffer is flushed.
		0	Receive serializers are cleared.
		1	Receive serializers are active.
1	RHCLKRST		Receive high-frequency clock divider reset enable bit.
		0	Receive high-frequency clock divider is held in reset and passes through its input as divide-by-1.
		1	Receive high-frequency clock divider is running.
0	RCLKRST		Receive high-frequency clock divider reset enable bit.
		0	Receive clock divider is held in reset. When the clock divider is in reset, it passes through a divide-by-1 of its input.
		1	Receive clock divider is running.

Table 22-20. Audio Mute Control Register (AMUTE) Field Descriptions

Bit	Field	Value	Description
31-13	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
12	XDMAERR		If transmit DMA error (XDMAERR), drive AMUTE active enable bit.
		0	Drive is disabled. Detection of transmit DMA error is ignored by AMUTE.
		1	Drive is enabled (active). Upon detection of transmit DMA error, AMUTE is active and is driven according to MUTEN bit.
11	RDMAERR		If receive DMA error (RDMAERR), drive AMUTE active enable bit.
		0	Drive is disabled. Detection of receive DMA error is ignored by AMUTE.
		1	Drive is enabled (active). Upon detection of receive DMA error, AMUTE is active and is driven according to MUTEN bit.
10	XCKFAIL		If transmit clock failure (XCKFAIL), drive AMUTE active enable bit.
		0	Drive is disabled. Detection of transmit clock failure is ignored by AMUTE.
		1	Drive is enabled (active). Upon detection of transmit clock failure, AMUTE is active and is driven according to MUTEN bit
9	RCKFAIL		If receive clock failure (RCKFAIL), drive AMUTE active enable bit.
		0	Drive is disabled. Detection of receive clock failure is ignored by AMUTE.
		1	Drive is enabled (active). Upon detection of receive clock failure, AMUTE is active and is driven according to MUTEN bit.
8	XSYNCERR		If unexpected transmit frame sync error (XSYNCERR), drive AMUTE active enable bit.
		0	Drive is disabled. Detection of unexpected transmit frame sync error is ignored by AMUTE.
		1	Drive is enabled (active). Upon detection of unexpected transmit frame sync error, AMUTE is active and is driven according to MUTEN bit.
7	RSYNCERR		If unexpected receive frame sync error (RSYNCERR), drive AMUTE active enable bit.
		0	Drive is disabled. Detection of unexpected receive frame sync error is ignored by AMUTE.
		1	Drive is enabled (active). Upon detection of unexpected receive frame sync error, AMUTE is active and is driven according to MUTEN bit.
6	XUNDRN		If transmit underrun error (XUNDRN), drive AMUTE active enable bit.
		0	Drive is disabled. Detection of transmit underrun error is ignored by AMUTE.
		1	Drive is enabled (active). Upon detection of transmit underrun error, AMUTE is active and is driven according to MUTEN bit.

Table 22-20. Audio Mute Control Register (AMUTE) Field Descriptions (continued)

Bit	Field	Value	Description
5	ROVRN		If receiver overrun error (ROVRN), drive AMUTE active enable bit.
		0	Drive is disabled. Detection of receiver overrun error is ignored by AMUTE.
		1	Drive is enabled (active). Upon detection of receiver overrun error, AMUTE is active and is driven according to MUTEN bit.
4	INSTAT		Determines drive on AXRn pin when PFUNC[n] and PDIR[n] bits are set to 1.
		0	AMUTEIN pin is inactive.
		1	AMUTEIN pin is active. Audio mute in error is detected.
3	INEN		Drive AMUTE active when AMUTEIN error is active (INSTAT = 1).
		0	Drive is disabled. AMUTEIN is ignored by AMUTE.
		1	Drive is enabled (active). INSTAT = 1 drives AMUTE active.
2	INPOL		Audio mute in (AMUTEIN) polarity select bit.
		0	Polarity is active high. A high on AMUTEIN sets INSTAT to 1.
		1	Polarity is active low. A low on AM UTEIN sets INSTAT to 1.
1-0	MUTEN	0-3h	AMUTE pin enable bit (unless overridden by GPIO registers).
		0	AMUTE pin is disabled, pin goes to tri-state condition.
		1h	AMUTE pin is driven high if error is detected.
		2h	AMUTE pin is driven low if error is detected.
		3h	Reserved

R-0	

15	4	3	2	1	0
Reserved		MODE		ORD	DLBEN
R-0		R/W-0		R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 22-21. Digital Loopback Control Register (DLBCTL) Field Descriptions

Bit	Field	Value	Description
31-4	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
3-2	MODE	0-3h	Loopback generator mode bits. Applies only when loopback mode is enabled (DLBEN = 1).
		0	Default and reserved on loopback mode (DLBEN = 1). When in non-loopback mode (DLBEN = 0), MODE should be left at default (00). When in loopback mode (DLBEN = 1), MODE = 00 is reserved and is not applicable.
		1h	Transmit clock and frame sync generators used by both transmit and receive sections. When in loopback mode (DLBEN = 1), MODE must be 01.
		2h-3h	Reserved.
1	ORD		Loopback order bit when loopback mode is enabled (DLBEN = 1).
		0	Odd serializers N + 1 transmit to even serializers N that receive. The corresponding serializers must be programmed properly.
		1	Even serializers N transmit to odd serializers N + 1 that receive. The corresponding serializers must be programmed properly.
0	DLBEN		Loopback mode enable bit.
		0	Loopback mode is disabled.
		1	Loopback mode is enabled.

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 22-22. Digital Mode Control Register (DITCTL) Field Descriptions

Bit	Field	Value	Description
31-4	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
3	VB		Valid bit for odd time slots (DIT right subframe).
		0	V bit is 0 during odd DIT subframes.
		1	V bit is 1 during odd DIT subframes.
2	VA		Valid bit for even time slots (DIT left subframe).
		0	V bit is 0 during even DIT subframes.
		1	V bit is 1 during even DIT subframes.
1	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
0	DITEN		DIT mode enable bit. DITEN should only be changed while the XSMRST bit in GBLCTL is in reset (and for startup, XSRCLR also in reset). However, it is not necessary to reset the XCLKRST or XHCLKRST bits in GBLCTL to change DITEN.
		0	DIT mode is disabled. Transmitter operates in TDM or burst mode.
		1	DIT mode is enabled. Transmitter operates in DIT encoded mode.

22.4.1.12 Receiver Global Control Register (RGBLCTL)

Alias of the global control register (GBLCTL). Writing to the receiver global control register (RGBLCTL) affects only the receive bits of GBLCTL (bits 4-0). Reads from RGBLCTL return the value of GBLCTL. RGBLCTL allows the receiver to be reset independently from the transmitter. The RGBLCTL is shown in Figure 22-50 and described in Table 22-23. See Section 22.4.1.8 for a detailed description of GBLCTL.

Table 22-23. Receiver Global Control Register (RGBLCTL) Field Descriptions

Bit	Field	Value	Description
31-13	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
12	XFRST	x	Transmit frame sync generator reset enable bit. A read of this bit returns the XFRST bit value of GBLCTL. Writes have no effect.
11	XSMRST	x	Transmit state machine reset enable bit. A read of this bit returns the XSMRST bit value of GBLCTL. Writes have no effect.
10	XSRCLR	x	Transmit serializer clear enable bit. A read of this bit returns the XSRCLR bit value of GBLCTL. Writes have no effect.
9	XHCLKRST	x	Transmit high-frequency clock divider reset enable bit. A read of this bit returns the XHCLKRST bit value of GBLCTL. Writes have no effect.
8	XCLKRST	x	Transmit clock divider reset enable bit. A read of this bit returns the XCLKRST bit value of GBLCTL. Writes have no effect.
7-5	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
4	RFRST		Receive frame sync generator reset enable bit. A write to this bit affects the RFRST bit of GBLCTL.
		0	Receive frame sync generator is reset.
		1	Receive frame sync generator is active.
3	RSMRST		Receive state machine reset enable bit. A write to this bit affects the RSMRST bit of GBLCTL.
		0	Receive state machine is held in reset.
		1	Receive state machine is released from reset.
2	RSRCLR		Receive serializer clear enable bit. A write to this bit affects the RSRCLR bit of GBLCTL.
		0	Receive serializers are cleared.
		1	Receive serializers are active.
1	RHCLKRST		Receive high-frequency clock divider reset enable bit. A write to this bit affects the RHCLKRST bit of GBLCTL.
		0	Receive high-frequency clock divider is held in reset and passes through its input as divide-by-1.
		1	Receive high-frequency clock divider is running.
0	RCLKRST		Receive clock divider reset enable bit. A write to this bit affects the RCLKRST bit of GBLCTL.
		0	Receive clock divider is held in reset.
		1	Receive clock divider is running.

22.4.1.13 Receive Format Unit Bit Mask Register (RMASK)

The receive format unit bit mask register (RMASK) determines which bits of the received data are masked off and padded with a known value before being read by the CPU or DMA. The RMASK is shown in Figure 22-51 and described in Table 22-24.

Figure 22-51. Receive Format Unit Bit Mask Register (RMASK)

31	0
RMASK[*n*]	
R/W-0	

LEGEND: R/W = Read/Write; -*n* = value after reset

Table 22-24. Receive Format Unit Bit Mask Register (RMASK) Field Descriptions

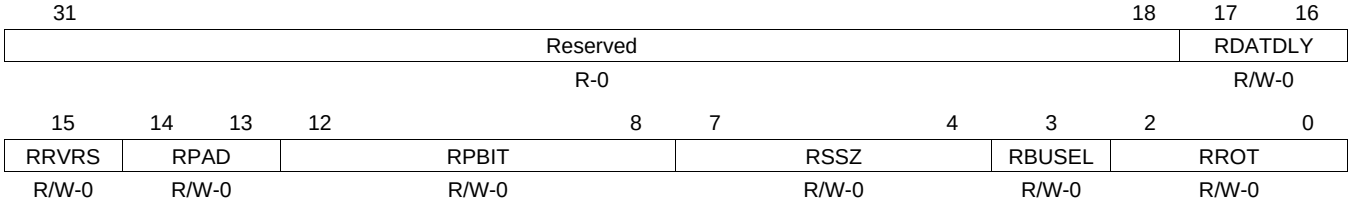
Bit	Field	Value	Description
31-0	RMASK[31-0]		Receive data mask *n* enable bit.
		0	Corresponding bit of receive data (after passing through reverse and rotate units) is masked out and then padded with the selected bit pad value (RPAD and RPBIT bits in RFMT).
		1	Corresponding bit of receive data (after passing through reverse and rotate units) is returned to CPU or DMA.

Copyright © 2011, Texas Instruments Incorporated

22.4.1.14 Receive Bit Stream Format Register (RFMT)

The receive bit stream format register (RFMT) configures the receive data format. The RFMT is shown in Figure 22-52 and described in Table 22-25.

Figure 22-52. Receive Bit Stream Format Register (RFMT)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 22-25. Receive Bit Stream Format Register (RFMT) Field Descriptions

Bit	Field	Value	Description
31-18	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
17-16	RDATDLY	0-3h	Receive bit delay.
		0	0-bit delay. The first receive data bit, AXRn, occurs in same ACLKR cycle as the receive frame sync (AFSR).
		1h	1-bit delay. The first receive data bit, AXRn, occurs one ACLKR cycle after the receive frame sync (AFSR).
		2h	2-bit delay. The first receive data bit, AXRn, occurs two ACLKR cycles after the receive frame sync (AFSR).
		3h	Reserved.
15	RRVRS		Receive serial bitstream order.
		0	Bitstream is LSB first. No bit reversal is performed in receive format bit reverse unit.
		1	Bitstream is MSB first. Bit reversal is performed in receive format bit reverse unit.
14-13	RPAD	0-3h	Pad value for extra bits in slot not belonging to the word. This field only applies to bits when RMASK[n] = 0.
		0	Pad extra bits with 0.
		1h	Pad extra bits with 1.
		2h	Pad extra bits with one of the bits from the word as specified by RPBIT bits.
		3h	Reserved.
12-8	RPBIT	0-1Fh	RPBIT value determines which bit (as read by the CPU or DMA from RBUF[n]) is used to pad the extra bits. This field only applies when RPAD = 2h.
		0	Pad with bit 0 value.
		1h-1Fh	Pad with bit 1 to bit 31 value.

Copyright © 2011, Texas Instruments Incorporated

Table 22-25. Receive Bit Stream Format Register (RFMT) Field Descriptions (continued)

Bit	Field	Value	Description
7-4	RSSZ	0-Fh	Receive slot size.
		0-2h	Reserved
		3h	Slot size is 8 bits.
		4h	Reserved
		5h	Slot size is 12 bits.
		6h	Reserved

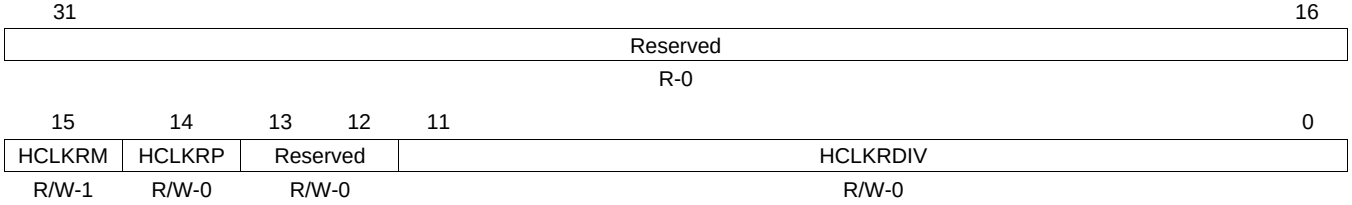
22.4.1.17 Receive High-Frequency Clock Control Register (AHCLKRCTL)

The receive high-frequency clock control register (AHCLKRCTL) configures the receive high-frequency master clock (AHCLKR) and the receive clock generator. The AHCLKRCTL is shown in Figure 22-55 and described in Table 22-28.

Figure 22-55. Receive High-Frequency Clock Control Register (AHCLKRCTL)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 22-28. Receive High-Frequency Clock Control Register (AHCLKRCTL) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
15	HCLKRM		Receive high-frequency clock source bit.
		0	External receive high-frequency clock source from AHCLKR pin.
		1	Internal receive high-frequency clock source from output of programmable high clock divider.
14	HCLKRP		Receive bitstream high-frequency clock polarity select bit.
		0	AHCLKR is not inverted before programmable bit clock divider. In the special case where the receive bit clock (ACLKR) is internally generated and the programmable bit clock divider is set to divide-by-1 (CLKRDIV = 0 in ACLKRCTL), AHCLKR is directly passed through to the ACLKR pin.
		1	AHCLKR is inverted before programmable bit clock divider. In the special case where the receive bit clock (ACLKR) is internally generated and the programmable bit clock divider is set to divide-by-1 (CLKRDIV = 0 in ACLKRCTL), AHCLKR is directly passed through to the ACLKR pin.
13-12	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
11-0	HCLKRDIV	0-FFFh	Receive high-frequency clock divide ratio bits determine the divide-down ratio from AUXCLK to AHCLKR.
		0	Divide-by-1.
		1h	Divide-by-2.

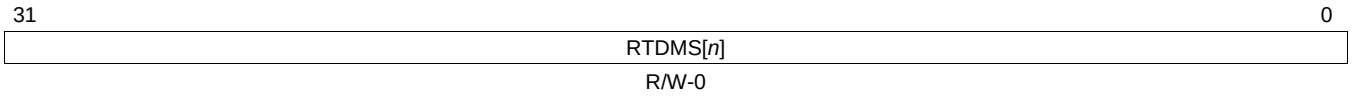
22.4.1.18 Receive TDM Time Slot Register (RTDM)

The receive TDM time slot register (RTDM) specifies which TDM time slot the receiver is active. The RTDM is shown in Figure 22-56 and described in Table 22-29.

Figure 22-56. Receive TDM Time Slot Register (RTDM)



LEGEND: R/W = Read/Write; -*n* = value after reset

Table 22-29. Receive TDM Time Slot Register (RTDM) Field Descriptions

Bit	Field	Value	Description
31-0	RTDMS[31-0]		Receiver mode during TDM time slot *n*.
		0	Receive TDM time slot *n* is inactive. The receive serializer does not shift in data during this slot.
		1	Receive TDM time slot *n* is active. The receive serializer shifts in data during this slot.

22.4.1.19 Receiver Interrupt Control Register (RINTCTL)

The receiver interrupt control register (RINTCTL) controls generation of the McASP receive interrupt (RINT). When the register bit(s) is set to 1, the occurrence of the enabled McASP condition(s) generates RINT. The RINTCTL is shown in Figure 22-57 and described in Table 22-30. See Section 22.4.1.20 for a description of the interrupt conditions.

Figure 22-57. Receiver Interrupt Control Register (RINTCTL)

31							8

RSTAFRM	Reserved	RDATA	RLAST	RDMAERR	RCKFAIL	RSYNCERR	ROVRN
R/W-0	R-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 22-30. Receiver Interrupt Control Register (RINTCTL) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
7	RSTAFRM		Receive start of frame interrupt enable bit.
		0	Interrupt is disabled. A receive start of frame interrupt does not generate a McASP receive interrupt (RINT).
		1	Interrupt is enabled. A receive start of frame interrupt generates a McASP receive interrupt (RINT).
6	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
5	RDATA		Receive data ready interrupt enable bit.
		0	Interrupt is disabled. A receive data ready interrupt does not generate a McASP receive interrupt (RINT).
		1	Interrupt is enabled. A receive data ready interrupt generates a McASP receive interrupt (RINT).
4	RLAST		Receive last slot interrupt enable bit.
		0	Interrupt is disabled. A receive last slot interrupt does not generate a McASP receive interrupt (RINT).
		1	Interrupt is enabled. A receive last slot interrupt generates a McASP receive interrupt (RINT).
3	RDMAERR		Receive DMA error interrupt enable bit.
		0	Interrupt is disabled. A receive DMA error interrupt does not generate a McASP receive interrupt (RINT).
		1	Interrupt is enabled. A receive DMA error interrupt generates a McASP receive interrupt (RINT).
2	RCKFAIL		Receive clock failure interrupt enable bit.
		0	Interrupt is disabled. A receive clock failure interrupt does not generate a McASP receive interrupt (RINT).
		1	Interrupt is enabled. A receive clock failure interrupt generates a McASP receive interrupt (RINT).
1	RSYNCERR		Unexpected receive frame sync interrupt enable bit.
		0	Interrupt is disabled. An unexpected receive frame sync interrupt does not generate a McASP receive interrupt (RINT).
		1	Interrupt is enabled. An unexpected receive frame sync interrupt generates a McASP receive interrupt (RINT).
0	ROVRN		Receiver overrun interrupt enable bit.
		0	Interrupt is disabled. A receiver overrun interrupt does not generate a McASP receive interrupt (RINT).
		1	Interrupt is enabled. A receiver overrun interrupt generates a McASP receive interrupt (RINT).

Copyright © 2011, Texas Instruments Incorporated

22.4.1.20 Receiver Status Register (RSTAT)

The receiver status register (RSTAT) provides the receiver status and receive TDM time slot number. If the McASP logic attempts to set an interrupt flag in the same cycle that the CPU writes to the flag to clear it, the McASP logic has priority and the flag remains set. This also causes a new interrupt request to be generated. The RSTAT is shown in Figure 22-58 and described in Table 22-31.

Figure 22-58. Receiver Status Register (RSTAT)

31							9	8
Reserved								RERR
R-0								R/W-0

R/W1C-0	R/W1C-0	R/W1C-0	R/W1C-0	R-0	R/W1C-0	R/W1C-0		R/W1C-0

LEGEND: R/W = Read/Write; R = Read only; W1C = Writing a 1 clears this bit; writing a 0 has no effect.; -*n* = value after reset

Table 22-31. Receiver Status Register (RSTAT) Field Descriptions

Bit	Field	Value	Description
31-9	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
8	RERR		RERR bit always returns a logic-OR of:ROVRN | RSYNCERR | RCKFAIL | RDMAERR Allows a single bit to be checked to determine if a receiver error interrupt has occurred.
		0	No errors have occurred.
		1	An error has occurred.
7	RDMAERR		Receive DMA error flag. RDMAERR is set when the CPU or DMA reads more serializers through the data port in a given time slot than were programmed as receivers. Causes a receive interrupt (RINT), if this bit is set and RDMAERR in RINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect.
		0	Receive DMA error did not occur.
		1	Receive DMA error did occur.
6	RSTAFRM		Receive start of frame flag. Causes a receive interrupt (RINT), if this bit is set and RSTAFRM in RINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect.
		0	No new receive frame sync (AFSR) is detected.
		1	A new receive frame sync (AFSR) is detected.
5	RDATA		Receive data ready flag. Causes a receive interrupt (RINT), if this bit is set and RDATA in RINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect.
		0	No new data in RBUF.
		1	Data is transferred from XRSR to RBUF and ready to be serviced by the CPU or DMA. When RDATA is set, it always causes a DMA event (AREVT).
4	RLAST		Receive last slot flag. RLAST is set along with RDATA, if the current slot is the last slot in a frame. Causes a receive interrupt (RINT), if this bit is set and RLAST in RINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect.
		0	Current slot is not the last slot in a frame.
		1	Current slot is the last slot in a frame. RDATA is also set.
3	RTDMSLOT		Returns the LSB of RSLOT. Allows a single read of RSTAT to determine whether the current TDM time slot is even or odd.
		0	Current TDM time slot is odd.
		1	Current TDM time slot is even.
2	RCKFAIL		Receive clock failure flag. RCKFAIL is set when the receive clock failure detection circuit reports an error (see *Clock Failure Detection*). Causes a receive interrupt (RINT), if this bit is set and RCKFAIL in RINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect.
		0	Receive clock failure did not occur.
		1	Receive clock failure did occur.

Copyright © 2011, Texas Instruments Incorporated

Table 22-31. Receiver Status Register (RSTAT) Field Descriptions (continued)

Bit	Field	Value	Description
1	RSYNCERR		Unexpected receive frame sync flag. RSYNCERR is set when a new receive frame sync (AFSR) occurs before it is expected. Causes a receive interrupt (RINT), if this bit is set and RSYNCERR in RINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect.
		0	Unexpected receive frame sync did not occur.
		1	Unexpected receive frame sync did occur.
0	ROVRN		Receiver overrun flag. ROVRN is set when the receive serializer is instructed to transfer data from XRSR to RBUF, but the former data in RBUF has not yet been read by the CPU or DMA. Causes a receive interrupt (RINT), if this bit is set and ROVRN in RINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect.
		0	Receiver overrun did not occur.
		1	Receiver overrun did occur.

22.4.1.21 Current Receive TDM Time Slot Registers (RSLOT)

The current receive TDM time slot register (RSLOT) indicates the current time slot for the receive data frame. The RSLOT is shown in Figure 22-59 and described in Table 22-32.

Figure 22-59. Current Receive TDM Time Slot Registers (RSLOT)

22.4.1.22 Receive Clock Check Control Register (RCLKCHK)

The receive clock check control register (RCLKCHK) configures the receive clock failure detection circuit. The RCLKCHK is shown in Figure 22-60 and described in Table 22-33.

Figure 22-60. Receive Clock Check Control Register (RCLKCHK)

31	24	23	16
RCNT		RMAX	
R-0		R/W-0	

15	8	7	4	3	0
RMIN		Reserved		RPS	
R/W-0		R-0		R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 22-33. Receive Clock Check Control Register (RCLKCHK) Field Descriptions

Bit	Field	Value	Description
31-24	RCNT	0-FFh	Receive clock count value (from previous measurement). The clock circuit continually counts the number of system clocks for every 32 receive high-frequency master clock (AHCLKR) signals, and stores the count in RCNT until the next measurement is taken.
23-16	RMAX	0-FFh	Receive clock maximum boundary. This 8-bit unsigned value sets the maximum allowed boundary for the clock check counter after 32 receive high-frequency master clock (AHCLKR) signals have been received. If the current counter value is greater than RMAX after counting 32 AHCLKR signals, RCKFAIL in RSTAT is set. The comparison is performed using unsigned arithmetic.
15-8	RMIN	0-FFh	Receive clock minimum boundary. This 8-bit unsigned value sets the minimum allowed boundary for the clock check counter after 32 receive high-frequency master clock (AHCLKR) signals have been received. If RCNT is less than RMIN after counting 32 AHCLKR signals, RCKFAIL in RSTAT is set. The comparison is performed using unsigned arithmetic.
7-4	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
3-0	RPS	0-Fh	Receive clock check prescaler value.
		0	McASP system clock divided by 1.
		1h	McASP system clock divided by 2.
		2h	McASP system clock divided by 4.
		3h	McASP system clock divided by 8.
		4h	McASP system clock divided by 16.
		5h	McASP system clock divided by 32.
		6h	McASP system clock divided by 64.
		7h	McASP system clock divided by 128.
		8h	McASP system clock divided by 256.
		9h-Fh	Reserved.

22.4.1.23 Receiver DMA Event Control Register (REVTCTL)

The receiver DMA event control register (REVTCTL) contains a disable bit for the receiver DMA event. The REVTCTL is shown in Figure 22-61 and described in Table 22-34.

NOTE: Device-specific registers

Accessing REVTCTL not implemented on a specific device may cause improper device operation.

22.4.1.24 Transmitter Global Control Register (XGBLCTL)

Alias of the global control register (GBLCTL). Writing to the transmitter global control register (XGBLCTL) affects only the transmit bits of GBLCTL (bits 12-8). Reads from XGBLCTL return the value of GBLCTL. XGBLCTL allows the transmitter to be reset independently from the receiver. The XGBLCTL is shown in Figure 22-62 and described in Table 22-35. See Section 22.4.1.8 for a detailed description of GBLCTL.

Table 22-35. Transmitter Global Control Register (XGBLCTL) Field Descriptions

Bit	Field	Value	Description
31-13	Reserved	0-FFh	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
12	XFRST		Transmit frame sync generator reset enable bit. A write to this bit affects the XFRST bit of GBLCTL.
		0	Transmit frame sync generator is reset.
		1	Transmit frame sync generator is active.
11	XSMRST		Transmit state machine reset enable bit. A write to this bit affects the XSMRST bit of GBLCTL.
		0	Transmit state machine is held in reset.
		1	Transmit state machine is released from reset.
10	XSRCLR		Transmit serializer clear enable bit. A write to this bit affects the XSRCLR bit of GBLCTL.
		0	Transmit serializers are cleared.
		1	Transmit serializers are active.
9	XHCLKRST		Transmit high-frequency clock divider reset enable bit. A write to this bit affects the XHCLKRST bit of GBLCTL.
		0	Transmit high-frequency clock divider is held in reset.
		1	Transmit high-frequency clock divider is running.
8	XCLKRST		Transmit clock divider reset enable bit. A write to this bit affects the XCLKRST bit of GBLCTL.
		0	Transmit clock divider is held in reset.
		1	Transmit clock divider is running.
7-5	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
4	RFRST	x	Receive frame sync generator reset enable bit. A read of this bit returns the RFRST bit value of GBLCTL. Writes have no effect.
3	RSMRST	x	Receive state machine reset enable bit. A read of this bit returns the RSMRST bit value of GBLCTL. Writes have no effect.
2	RSRCLR	x	Receive serializer clear enable bit. A read of this bit returns the RSRSCLR bit value of GBLCTL. Writes have no effect.
1	RHCLKRST	x	Receive high-frequency clock divider reset enable bit. A read of this bit returns the RHCLKRST bit value of GBLCTL. Writes have no effect.
0	RCLKRST	x	Receive clock divider reset enable bit. A read of this bit returns the RCLKRST bit value of GBLCTL. Writes have no effect.

22.4.1.25 Transmit Format Unit Bit Mask Register (XMASK)

The transmit format unit bit mask register (XMASK) determines which bits of the transmitted data are masked off and padded with a known value before being shifted out the McASP. The XMASK is shown in Figure 22-63 and described in Table 22-36.

Figure 22-63. Transmit Format Unit Bit Mask Register (XMASK)

31	0
XMASK[*n*]	
R/W-0	

LEGEND: R/W = Read/Write; -*n* = value after reset

Table 22-36. Transmit Format Unit Bit Mask Register (XMASK) Field Descriptions

Bit	Field	Value	Description
31-0	XMASK[31-0]		Transmit data mask *n* enable bit.
		0	Corresponding bit of transmit data (before passing through reverse and rotate units) is masked out and then padded with the selected bit pad value (XPAD and XPBIT bits in XFMT), which is transmitted out the McASP in place of the original bit.
		1	Corresponding bit of transmit data (before passing through reverse and rotate units) is transmitted out the McASP.

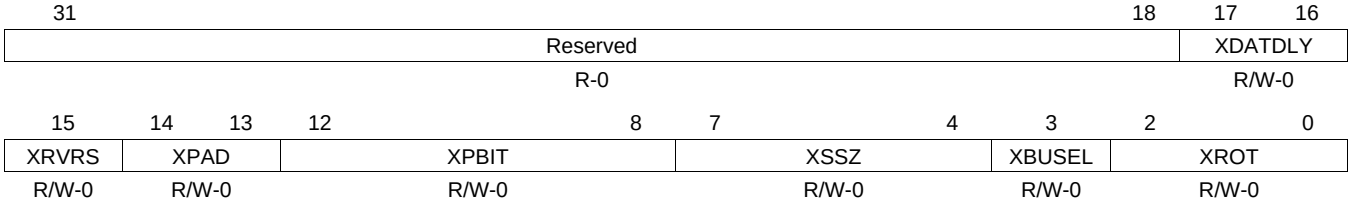
22.4.1.26 Transmit Bit Stream Format Register (XFMT)

The transmit bit stream format register (XFMT) configures the transmit data format. The XFMT is shown in Figure 22-64 and described in Table 22-37.

Figure 22-64. Transmit Bit Stream Format Register (XFMT)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 22-37. Transmit Bit Stream Format Register (XFMT) Field Descriptions

Bit	Field	Value	Description
31-18	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
17-16	XDATDLY	0-3h	Transmit sync bit delay.
		0	0-bit delay. The first transmit data bit, AXRn, occurs in same ACLKX cycle as the transmit frame sync (AFSX).
		1h	1-bit delay. The first transmit data bit, AXRn, occurs one ACLKX cycle after the transmit frame sync (AFSX).
		2h	2-bit delay. The first transmit data bit, AXRn, occurs two ACLKX cycles after the transmit frame sync (AFSX).
		3h	Reserved.
15	XRVRS		Transmit serial bitstream order.
		0	Bitstream is LSB first. No bit reversal is performed in transmit format bit reverse unit.
		1	Bitstream is MSB first. Bit reversal is performed in transmit format bit reverse unit.
14-13	XPAD	0-3h	Pad value for extra bits in slot not belonging to word defined by XMASK. This field only applies to bits when XMASK[n] = 0.
		0	Pad extra bits with 0.
		1h	Pad extra bits with 1.
		2h	Pad extra bits with one of the bits from the word as specified by XPBIT bits.
		3h	Reserved.
12-8	XPBIT	0-1Fh	XPBIT value determines which bit (as written by the CPU or DMA to XBUF[n]) is used to pad the extra bits before shifting. This field only applies when XPAD = 2h.
		0	Pad with bit 0 value.
		1-1Fh	Pad with bit 1 to bit 31 value.

Copyright © 2011, Texas Instruments Incorporated

Table 22-37. Transmit Bit Stream Format Register (XFMT) Field Descriptions (continued)

Bit	Field	Value	Description
7-4	XSSZ	0-Fh	Transmit slot size.
		0-2h	Reserved.
		3h	Slot size is 8 bits.
		4h	Reserved.
		5h	Slot size is 12 bits.
		6h	Reserved.
		7h	Slot size is 16 bits.
		8h	Reserved.
		9h	Slot size is 20 bits.
		Ah	Reserved.
		Bh	Slot size is 24 bits.
		Ch	Reserved.

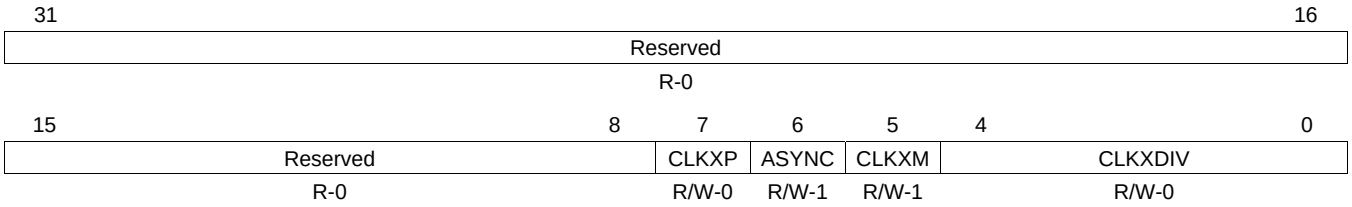
22.4.1.28 Transmit Clock Control Register (ACLKXCTL)

The transmit clock control register (ACLKXCTL) configures the transmit bit clock (ACLKX) and the transmit clock generator. The ACLKXCTL is shown in Figure 22-66 and described in Table 22-39.

Figure 22-66. Transmit Clock Control Register (ACLKXCTL)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 22-39. Transmit Clock Control Register (ACLKXCTL) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
7	CLKXP		Transmit bitstream clock polarity select bit.
		0	Rising edge. External receiver samples data on the falling edge of the serial clock, so the transmitter must shift data out on the rising edge of the serial clock.
		1	Falling edge. External receiver samples data on the rising edge of the serial clock, so the transmitter must shift data out on the falling edge of the serial clock.
6	ASYNC		Transmit/receive operation asynchronous enable bit.
		0	Synchronous. Transmit clock and frame sync provides the source for both the transmit and receive sections.
		1	Asynchronous. Separate clock and frame sync used by transmit and receive sections.
5	CLKXM		Transmit bit clock source bit.
		0	External transmit clock source from ACLKX pin.
		1	Internal transmit clock source from output of programmable bit clock divider.
4-0	CLKXDIV	0-1Fh	Transmit bit clock divide ratio bits determine the divide-down ratio from AHCLKX to ACLKX.
		0	Divide-by-1.
		1h	Divide-by-2.
		2h-1Fh	Divide-by-3 to divide-by-32.

22.4.1.30 Transmit TDM Time Slot Register (XTDM)

The transmit TDM time slot register (XTDM) specifies in which TDM time slot the transmitter is active. TDM time slot counter range is extended to 384 slots (to support SPDIF blocks of 384 subframes). XTDM operates modulo 32, that is, XTDMS specifies the TDM activity for time slots 0, 32, 64, 96, 128, etc. The XTDM is shown in Figure 22-68 and described in Table 22-41.

Figure 22-68. Transmit TDM Time Slot Register (XTDM)

22.4.1.31 Transmitter Interrupt Control Register (XINTCTL)

The transmitter interrupt control register (XINTCTL) controls generation of the McASP transmit interrupt (XINT). When the register bit(s) is set to 1, the occurrence of the enabled McASP condition(s) generates XINT. The XINTCTL is shown in Figure 22-69 and described in Table 22-42. See Section 22.4.1.32 for a description of the interrupt conditions.

Figure 22-69. Transmitter Interrupt Control Register (XINTCTL)

Table 22-42. Transmitter Interrupt Control Register (XINTCTL) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
7	XSTAFRM		Transmit start of frame interrupt enable bit.
		0	Interrupt is disabled. A transmit start of frame interrupt does not generate a McASP transmit interrupt (XINT).
		1	Interrupt is enabled. A transmit start of frame interrupt generates a McASP transmit interrupt (XINT).
6	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
5	XDATA		Transmit data ready interrupt enable bit.
		0	Interrupt is disabled. A transmit data ready interrupt does not generate a McASP transmit interrupt (XINT).
		1	Interrupt is enabled. A transmit data ready interrupt generates a McASP transmit interrupt (XINT).
4	XLAST		Transmit last slot interrupt enable bit.
		0	Interrupt is disabled. A transmit last slot interrupt does not generate a McASP transmit interrupt (XINT).
		1	Interrupt is enabled. A transmit last slot interrupt generates a McASP transmit interrupt (XINT).
3	XDMAERR		Transmit DMA error interrupt enable bit.
		0	Interrupt is disabled. A transmit DMA error interrupt does not generate a McASP transmit interrupt (XINT).
		1	Interrupt is enabled. A transmit DMA error interrupt generates a McASP transmit interrupt (XINT).
2	XCKFAIL		Transmit clock failure interrupt enable bit.
		0	Interrupt is disabled. A transmit clock failure interrupt does not generate a McASP transmit interrupt (XINT).
		1	Interrupt is enabled. A transmit clock failure interrupt generates a McASP transmit interrupt (XINT).
1	XSYNCERR		Unexpected transmit frame sync interrupt enable bit.
		0	Interrupt is disabled. An unexpected transmit frame sync interrupt does not generate a McASP transmit interrupt (XINT).
		1	Interrupt is enabled. An unexpected transmit frame sync interrupt generates a McASP transmit interrupt (XINT).
0	XUNDRN		Transmitter underrun interrupt enable bit.
		0	Interrupt is disabled. A transmitter underrun interrupt does not generate a McASP transmit interrupt (XINT).
		1	Interrupt is enabled. A transmitter underrun interrupt generates a McASP transmit interrupt (XINT).

Copyright © 2011, Texas Instruments Incorporated

22.4.1.32 Transmitter Status Register (XSTAT)

The transmitter status register (XSTAT) provides the transmitter status and transmit TDM time slot number. If the McASP logic attempts to set an interrupt flag in the same cycle that the CPU writes to the flag to clear it, the McASP logic has priority and the flag remains set. This also causes a new interrupt request to be generated. The XSTAT is shown in Figure 22-70 and described in Table 22-43.

Figure 22-70. Transmitter Status Register (XSTAT)

31							9	8
Reserved								XERR
R-0								R/W-0
7	6	5	4	3	2	1		0
XDMAERR	XSTAFRM	XDATA	XLAST	XTDMSLOT	XCKFAIL	XSYNCERR		XUNDRN
R/W1C-0	R/W1C-0	R/W1C-0	R/W1C-0	R-0	R/W1C-0	R/W1C-0		R/W1C-0

LEGEND: R/W = Read/Write; R = Read only; W1C = Writing a 1 clears this bit; writing a 0 has no effect; *-n* = value after reset

Table 22-43. Transmitter Status Register (XSTAT) Field Descriptions

Bit	Field	Value	Description
31-9	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
8	XERR		XERR bit always returns a logic-OR of:XUNDRN | XSYNCERR | XCKFAIL | XDMAERR Allows a single bit to be checked to determine if a transmitter error interrupt has occurred.
		0	No errors have occurred.
		1	An error has occurred.
7	XDMAERR		Transmit DMA error flag. XDMAERR is set when the CPU or DMA writes more serializers through the data port in a given time slot than were programmed as transmitters. Causes a transmit interrupt (XINT), if this bit is set and XDMAERR in XINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 has no effect.
		0	Transmit DMA error did not occur.
		1	Transmit DMA error did occur.
6	XSTAFRM		Transmit start of frame flag. Causes a transmit interrupt (XINT), if this bit is set and XSTAFRM in XINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 has no effect.
		0	No new transmit frame sync (AFSX) is detected.
		1	A new transmit frame sync (AFSX) is detected.
5	XDATA		Transmit data ready flag. Causes a transmit interrupt (XINT), if this bit is set and XDATA in XINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 has no effect.
		0	XBUF is written and is full.
		1	Data is copied from XBUF to XRSR. XBUF is empty and ready to be written. XDATA is also set when the transmit serializers are taken out of reset. When XDATA is set, it always causes a DMA event (AXEVT).
4	XLAST		Transmit last slot flag. XLAST is set along with XDATA, if the current slot is the last slot in a frame. Causes a transmit interrupt (XINT), if this bit is set and XLAST in XINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 has no effect.
		0	Current slot is not the last slot in a frame.
		1	Current slot is the last slot in a frame. XDATA is also set.
3	XTDMSLOT		Returns the LSB of XSLOT. Allows a single read of XSTAT to determine whether the current TDM time slot is even or odd.
		0	Current TDM time slot is odd.
		1	Current TDM time slot is even.
2	XCKFAIL		Transmit clock failure flag. XCKFAIL is set when the transmit clock failure detection circuit reports an error (see *Clock Failure Detection*). Causes a transmit interrupt (XINT), if this bit is set and XCKFAIL in XINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 has no effect.
		0	Transmit clock failure did not occur.
		1	Transmit clock failure did occur.

Copyright © 2011, Texas Instruments Incorporated

Table 22-43. Transmitter Status Register (XSTAT) Field Descriptions (continued)

Bit	Field	Value	Description
1	XSYNCERR		Unexpected transmit frame sync flag. XSYNCERR is set when a new transmit frame sync (AFSX) occurs before it is expected. Causes a transmit interrupt (XINT), if this bit is set and XSYNCERR in XINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 has no effect.
		0	Unexpected transmit frame sync did not occur.
		1	Unexpected transmit frame sync did occur.
0	XUNDRN		Transmitter underrun flag. XUNDRN is set when the transmit serializer is instructed to transfer data from XBUF to XRSR, but XBUF has not yet been serviced with new data since the last transfer. Causes a transmit interrupt (XINT), if this bit is set and XUNDRN in XINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 has no effect.
		0	Transmitter underrun did not occur.
		1	Transmitter underrun did occur. For details on McASP action upon underrun conditions, see *Buffer Underrun Error - Transmitter*.

22.4.1.33 Current Transmit TDM Time Slot Register (XSLOT)

The current transmit TDM time slot register (XSLOT) indicates the current time slot for the transmit data frame. The XSLOT is shown in Figure 22-71 and described in Table 22-44.

Figure 22-71. Current Transmit TDM Time Slot Register (XSLOT)

31	16
Reserved	
R-0

Reserved		XSLOTCNT	
R-0		R-17Fh	

LEGEND: R = Read only; -*n* = value after reset

Table 22-44. Current Transmit TDM Time Slot Register (XSLOT) Field Descriptions

Bit	Field	Value	Description
31-10	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
9-0	XSLOTCNT	0-17Fh	Current transmit time slot count. Legal values: 0 to 383 (17Fh). During reset, this counter value is 383 so the next count value, which is used to encode the first DIT group of data, will be 0 and encodes the B preamble. TDM function is not supported for >32 time slots. However, TDM time slot counter may count to 383 when used to transmit a DIT block.

22.4.1.34 Transmit Clock Check Control Register (XCLKCHK)

The transmit clock check control register (XCLKCHK) configures the transmit clock failure detection circuit. The XCLKCHK is shown in Figure 22-72 and described in Table 22-45.

Figure 22-72. Transmit Clock Check Control Register (XCLKCHK)

31	24	23	16
XCNT		XMAX	
R-0		R/W-0	

15	8	7	4	3	0
XMIN		Reserved		XPS	
R/W-0		R-0		R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 22-45. Transmit Clock Check Control Register (XCLKCHK) Field Descriptions

Bit	Field	Value	Description
31-24	XCNT	0	Transmit clock count value (from previous measurement). The clock circuit continually counts the number of system clocks for every 32 transmit high-frequency master clock (AHCLKX) signals, and stores the count in XCNT until the next measurement is taken.
23-16	XMAX	0-FFh	Transmit clock maximum boundary. This 8-bit unsigned value sets the maximum allowed boundary for the clock check counter after 32 transmit high-frequency master clock (AHCLKX) signals have been received. If the current counter value is greater than XMAX after counting 32 AHCLKX signals, XCKFAIL in XSTAT is set. The comparison is performed using unsigned arithmetic.
15-8	XMIN	0-FFh	Transmit clock minimum boundary. This 8-bit unsigned value sets the minimum allowed boundary for the clock check counter after 32 transmit high-frequency master clock (AHCLKX) signals have been received. If XCNT is less than XMIN after counting 32 AHCLKX signals, XCKFAIL in XSTAT is set. The comparison is performed using unsigned arithmetic.
7-4	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
3-0	XPS	0-Fh	Transmit clock check prescaler value.
		0	McASP system clock divided by 1.
		1h	McASP system clock divided by 2.
		2h	McASP system clock divided by 4.
		3h	McASP system clock divided by 8.
		4h	McASP system clock divided by 16.
		5h	McASP system clock divided by 32.
		6h	McASP system clock divided by 64.
		7h	McASP system clock divided by 128.
		8h	McASP system clock divided by 256.
		9h-Fh	Reserved.

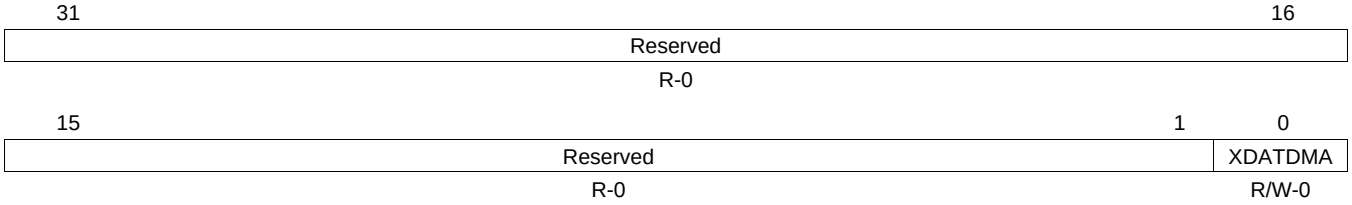
22.4.1.35 Transmitter DMA Event Control Register (XEVTCTL)

The transmitter DMA event control register (XEVTCTL) contains a disable bit for the transmit DMA event. The XEVTCTL is shown in Figure 22-73 and described in Table 22-46.

NOTE: Device-specific registers

Accessing REVTCTL not implemented on a specific device may cause improper device operation.

Figure 22-73. Transmitter DMA Event Control Register (XEVTCTL)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 22-46. Transmitter DMA Event Control Register (XEVTCTL) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
0	XDATDMA		Transmit data DMA request enable bit. If writing to this bit, always write the default value of 0.
		0	Transmit data DMA request is enabled.
		1	Reserved

22.4.1.36 Serializer Control Registers (SRCTL*n*)

Each serializer on the McASP has a serializer control register (SRCTL). There are up to 6 serializers per McASP. The SRCTL is shown in Figure 22-74 and described in Table 22-47.

NOTE: Device-specific registers

Accessing SRCTL*n* not implemented on a specific device may cause improper device operation.

Figure 22-74. Serializer Control Registers (SRCTL*n*)

31	16
Reserved	
R-0	

15	6	5	4	3	2	1	0
Reserved		RRDY	XRDY	DISMOD		SRMOD	
R-0		R-0	R-0	R/W-0		R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 22-47. Serializer Control Registers (SRCTL*n*) Field Descriptions

Bit	Field	Value	Description
31-6	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
5	RRDY		Receive buffer ready bit. RRDY indicates the current receive buffer state. Always reads 0 when programmed as a transmitter or as inactive. If SRMOD bit is set to receive (2h), RRDY switches from 0 to 1 whenever data is transferred from XRSR to RBUF.
		0	Receive buffer (RBUF) is empty.
		1	Receive buffer (RBUF) contains data and needs to be read before the start of the next time slot or a receiver overrun occurs.
4	XRDY		Transmit buffer ready bit. XRDY indicates the current transmit buffer state. Always reads 0 when programmed as a receiver or as inactive. If SRMOD bit is set to transmit (1h), XRDY switches from 0 to 1 when XSRCLR in GBLCTL is switched from 0 to 1 to indicate an empty transmitter. XRDY remains set until XSRCLR is forced to 0, data is written to the corresponding transmit buffer, or SRMOD bit is changed to receive (2h) or inactive (0).
		0	Transmit buffer (XBUF) contains data.
		1	Transmit buffer (XBUF) is empty and needs to be written before the start of the next time slot or a transmit underrun occurs.
3-2	DISMOD	0-3h	Serializer pin drive mode bit. Drive on pin when in inactive TDM slot of transmit mode or when serializer is inactive. This field only applies if the pin is configured as a McASP pin (PFUNC = 0).
		0	Drive on pin is 3-state.
		1h	Reserved.
		2h	Drive on pin is logic low.
		3h	Drive on pin is logic high.
1-0	SRMOD	0-3h	Serializer mode bit.
		0	Serializer is inactive.
		1h	Serializer is transmitter.
		2h	Serializer is receiver.
		3h	Reserved.

22.4.1.37 DIT Left Channel Status Registers (DITCSRA0-DITCSRA5)

The DIT left channel status registers (DITCSRA) provide the status of each left channel (even TDM time slot). Each of the six 32-bit registers (Figure 22-75) can store 192 bits of channel status data for a complete block of transmission. The DIT reuses the same data for the next block. It is your responsibility to update the register file in time, if a different set of data need to be sent.

Figure 22-75. DIT Left Channel Status Registers (DITCSRA0-DITCSRA5)

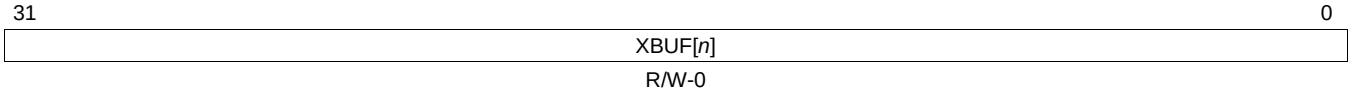
22.4.1.41 Transmit Buffer Registers (XBUF*n*)

The transmit buffers for the serializers (XBUF) hold data from the transmit format unit. For transmit operations, the XBUF (Figure 22-79) is an alias of the XRBUF in the serializer.

NOTE: Device-specific registers

Accessing XBUF registers not implemented on a specific device may cause improper device operation.

Figure 22-79. Transmit Buffer Registers (XBUFn)



LEGEND: R/W = Read/Write; -*n* = value after reset

22.4.1.42 Receive Buffer Registers (RBUF*n*)

The receive buffers for the serializers (RBUF) hold data from the serializer before the data goes to the receive format unit. For receive operations, the RBUF (Figure 22-80) is an alias of the XRBUF in the serializer.

NOTE: Device-specific registers

Accessing XBUF registers not implemented on a specific device may cause improper device operation.

Figure 22-80. Receive Buffer Registers (RBUF*n*)

22.4.1.43 Write FIFO Control Register (WFIFOCTL)

The Write FIFO control register (WFIFOCTL) is shown in Figure 22-81 and described in Table 22-48.

NOTE: The WNUMEVT and WNUMDMA values must be set prior to enabling the Write FIFO.

If the Write FIFO is to be enabled, it must be enabled prior to taking the McASP out of reset.

Figure 22-81. Write FIFO Control Register (WFIFOCTL)

Table 22-48. Write FIFO Control Register (WFIFOCTL) Field Descriptions

Bit	Field	Value	Description
31-17	Reserved	0	Reserved
16	WENA		Write FIFO enable bit.
		0	Write FIFO is disabled. The WLVL bit in the Write FIFO status register (WFIFOSTS) is reset to 0 and pointers are initialized, that is, the Write FIFO is "flushed."
		1	Write FIFO is enabled. If Write FIFO is to be enabled, it must be enabled prior to taking McASP out of reset.
15-8	WNUMEVT	0-FFh	Write word count per DMA event (32-bit). When the Write FIFO has space for at least WNUMEVT words of data, then an AXEVT (transmit DMA event) is generated to the host/DMA controller. This value should be set to a non-zero integer multiple of the number of serializers enabled as transmitters. This value must be set prior to enabling the Write FIFO.
		0	0 words
		1h	1 word
		2h	2 words
		3h-40h	3 to 64 words
		41h-FFh	Reserved
7-0	WNUMDMA	0-FFh	Write word count per transfer (32-bit words). Upon a transmit DMA event from the McASP, WNUMDMA words are transferred from the Write FIFO to the McASP. This value must equal the number of McASP serializers used as transmitters. This value must be set prior to enabling the Write FIFO.
		0	0 words
		1h	1 word
		2h	2 words
		3h-10h	3-16 words

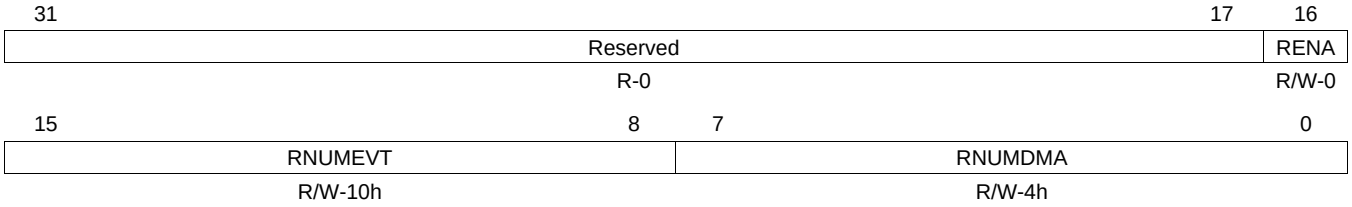
22.4.1.45 Read FIFO Control Register (RFIFOCTL)

The Read FIFO control register (RFIFOCTL) is shown in Figure 22-83 and described in Table 22-50.

NOTE: The RNUMEVT and RNUMDMA values must be set prior to enabling the Read FIFO.

If the Read FIFO is to be enabled, it must be enabled prior to taking the McASP out of reset.

Figure 22-83. Read FIFO Control Register (RFIFOCTL)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 22-50. Read FIFO Control Register (RFIFOCTL) Field Descriptions

Bit	Field	Value	Description
31-17	Reserved	0	Reserved
16	RENA		Read FIFO enable bit.
		0	Read FIFO is disabled. The RLVL bit in the Read FIFO status register (RFIFOSTS) is reset to 0 and pointers are initialized, that is, the Read FIFO is "flushed."
		1	Read FIFO is enabled. If Read FIFO is to be enabled, it must be enabled prior to taking McASP out of reset.
15-8	RNUMEVT	0-FFh	Read word count per DMA event (32-bit). When the Read FIFO contains at least RNUMEVT words of data, then an AREVT (receive DMA event) is generated to the host/DMA controller. This value should be set to a non-zero integer multiple of the number of serializers enabled as receivers. This value must be set prior to enabling the Read FIFO.
		0	0 words
		1h	1 word
		2h	2 words
		3h-40h	3 to 64 words
		41h-FFh	Reserved
7-0	RNUMDMA	0-FFh	Read word count per transfer (32-bit words). Upon a receive DMA event from the McASP, the Read FIFO reads RNUMDMA words from the McASP. This value must equal the number of McASP serializers used as receivers. This value must be set prior to enabling the Read FIFO.
		0	0 words
		1	1 word
		2	2 words
		3h-10h	3-16 words

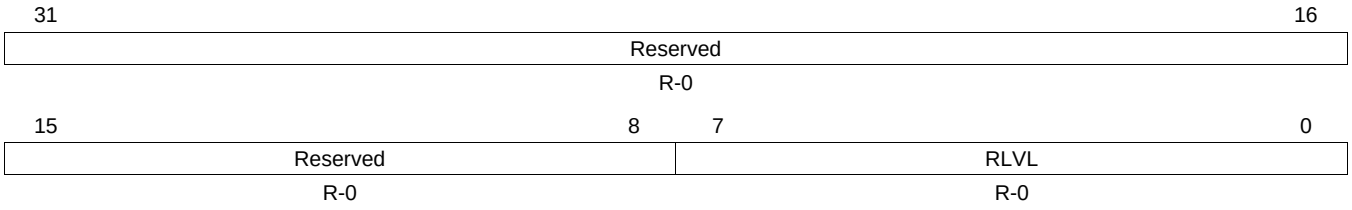
22.4.1.46 Read FIFO Status Register (RFIFOSTS)

The Read FIFO status register (RFIFOSTS) is shown in Figure 22-84 and described in Table 22-51.

Figure 22-84. Read FIFO Status Register (RFIFOSTS)



LEGEND: R = Read only; -*n* = value after reset

Table 22-51. Read FIFO Status Register (RFIFOSTS) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7-0	RLVL	0-FFh	Read level (read-only). Number of 32-bit words currently in the Read FIFO.
		0	0 words currently in Read FIFO.
		1h	1 word currently in Read FIFO.
		2h	2 words currently in Read FIFO.
		3h-40h	3 to 64 words currently in Read FIFO.
		41h-FFh	Reserved

22.4.2 McASP Data Port Registers

Table 22-52. McASP Registers Accessed Through Data Port

Hex Address	Register Name	Register Description
Read Accesses	RBUF	Receive buffer data port address. Cycles through receive serializers, skipping over transmit serializers and inactive serializers. Starts at the lowest serializer at the beginning of each time slot. DAT BUS only if XBUSEL = 0.
Write Accesses	XBUF	Transmit buffer data port address. Cycles through transmit serializers, skipping over receive and inactive serializers. Starts at the lowest serializer at the beginning of each time slot. DAT BUS only if RBUSEL = 0.

23.1 Introduction

23.1.1 DCAN Features

The general features of the DCAN controller are:

- Supports CAN protocol version 2.0 part A, B (ISO 11898-1)
- Bit rates up to 1 MBit/s
- Dual clock source
- 16, 32, 64 or 128 message objects (instantiated as 64 on this device)
- Individual identifier mask for each message object
- Programmable FIFO mode for message objects
- Programmable loop-back modes for self-test operation
- Suspend mode for debug support
- Software module reset
- Automatic bus on after Bus-Off state by a programmable 32-bit timer
- Message RAM parity check mechanism
- Direct access to Message RAM during test mode
- CAN Rx / Tx pins configurable as general purpose IO pins
- Two interrupt lines (plus additional parity-error interrupt line)
- RAM initialization
- DMA support

23.1.2 Unsupported DCAN Features

The DCAN module in this device does not support GPIO pin mode. All GPIO functionality is mapped through the GPIO modules and muxed at the pins. GPIO pin control signals from the DCAN modules are not connected.

Copyright © 2011, Texas Instruments Incorporated

23.2 Integration

The Controller Area Network is a serial communications protocol which efficiently supports distributed realtime control with a high level of security. The DCAN module supports bitrates up to 1 Mbit/s and is compliant to the CAN 2.0B protocol specification. The core IP within DCAN is provided by Bosch.

This device includes two instantiations of the DCAN controller: DCAN0 and DCAN1. Figure 23-1 shows the DCAN module integration.

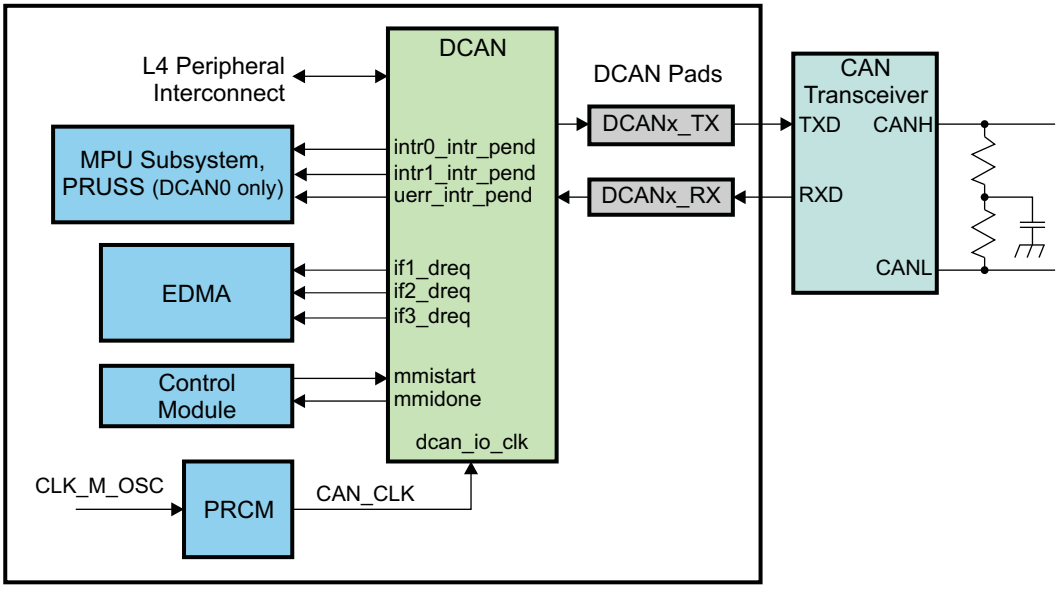

Figure 23-1. DCAN Integration

23.2.1 DCAN Connectivity Attributes

The general connectivity attributes for the DCAN module are shown in Table 23-1.

Table 23-1. DCAN Connectivity Attributes

Attributes	Type
Power Domain	Peripheral Domain
Clock Domain	PD_PER_L4LS_GCLK (OCP) PD_PER_CAN_CLK (Func)
Reset Signals	PER_DOM_RST_N
Idle/Wakeup Signals	Smart Idle
Interrupt Requests	3 Interrupts per instance Intr0 (DCANx_INT0) – Error, Status, Msg Object interrupt Intr1 (DCANx_INT1) – Msg Object interrupt Uerr (DCANx_PARITY) – Parity error interrupt All DCAN0 interrupts to MPU Subsystem and PRUSS All DCAN1 interrupts to only MPU Subsystem
DMA Requests	3 DMA requests per instance to EDMA (CAN_IFxDMA)
Physical Address	L4 Peripheral slave port

Copyright © 2011, Texas Instruments Incorporated

23.2.2 DCAN Clock and Reset Management

The DCAN controllers have separate bus interface and functional clocks.

Table 23-2. DCAN Clock Signals

Clock Signal	Max Freq	Reference / Source	Comments
DCAN_ocp_clk Interface clock	100 MHz	CORE_CLKOUTM4 / 2	pd_per_l4ls_gclk from PRCM
DCAN_io_clk Functional clock	26 MHz	CLK_M_OSC	pd_per_can_clk from PRCM

23.2.3 DCAN Pin List

The external signals for the DCAN module are shown in the following table.

Table 23-3. DCAN Pin List

Pin	Type	Description
DCAN*x*_TX	O	DCAN transmit line
DCAN*x*_RX	I	DCAN receive line

Copyright © 2011, Texas Instruments Incorporated

23.3 Functional Description

The DCAN module performs CAN protocol communication according to ISO 11898-1. The bit rate can be programmed to values up to 1 MBit/s. Additional transceiver hardware is required for the connection to the physical layer (CAN bus).

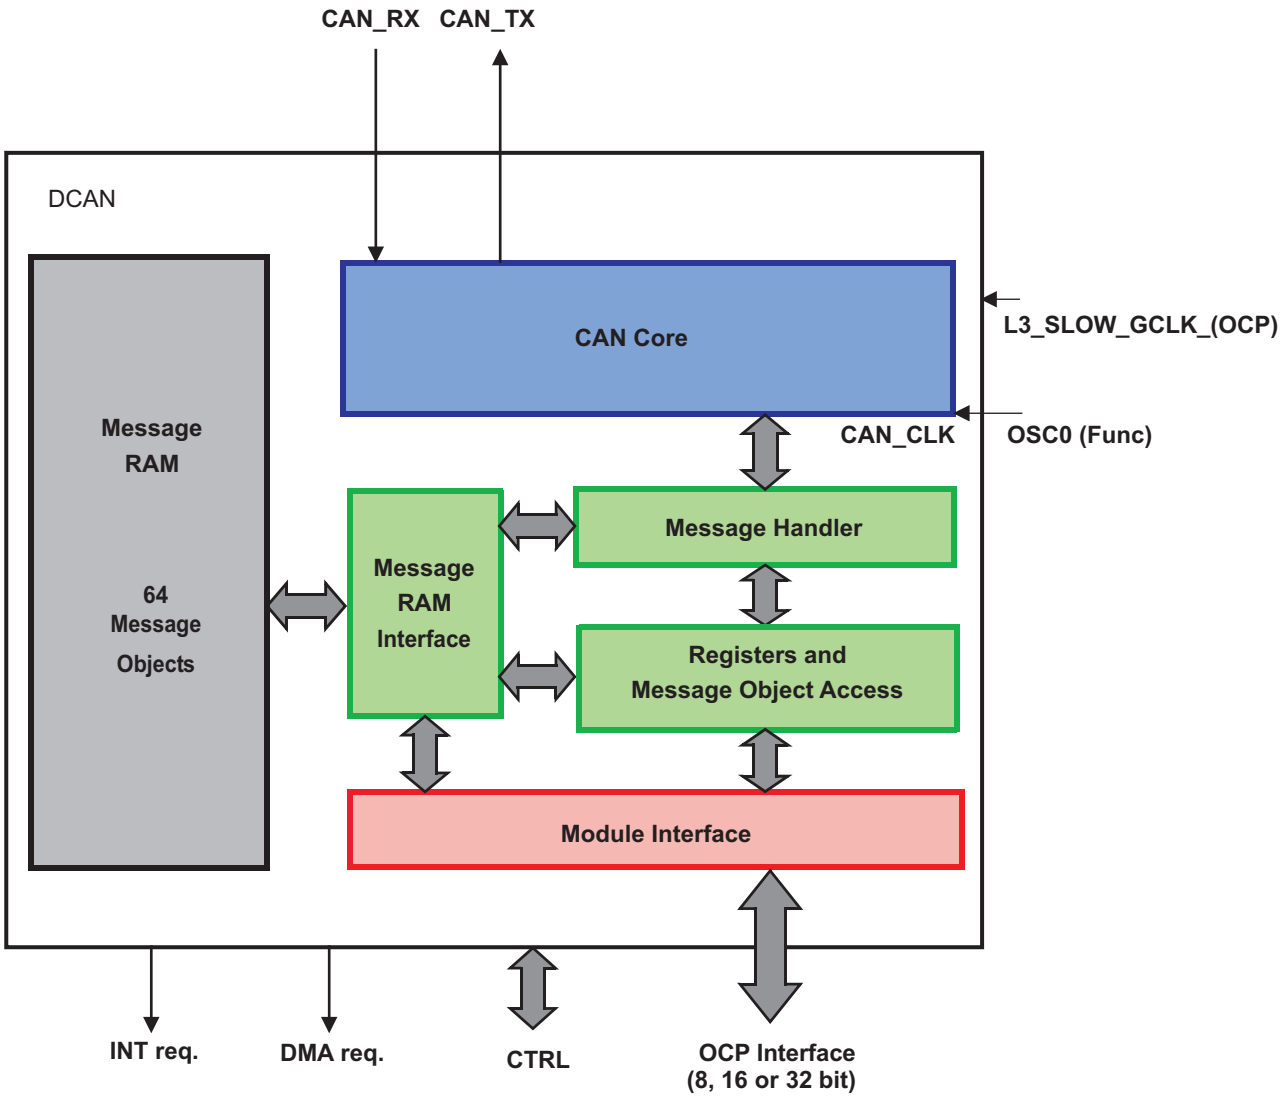
For communication on a CAN network, individual message objects can be configured. The message objects and identifier masks are stored in the message RAM.

All functions concerning the handling of messages are implemented in the message handler. Those functions are acceptance filtering, the transfer of messages between the CAN core and the message RAM, and the handling of transmission requests, as well as the generation of interrupts or DMA requests.

The register set of the DCAN module can be accessed directly by the CPU via the module interface. These registers are used to control and configure the CAN core and the message handler, and to access the message RAM.

Figure 23-2 shows the DCAN block diagram and its features are described below.

Figure 23-2. DCAN Block Diagram



Copyright © 2011, Texas Instruments Incorporated

23.3.0.1 CAN Core

The CAN core consists of the CAN protocol controller and the Rx/Tx shift register. It handles all ISO 11898-1 protocol functions.

23.3.0.2 Message Handler

The message handler is a state machine that controls the data transfer between the single-ported message RAM and the CAN core's Rx/Tx shift register. It also handles acceptance filtering and the interrupt/DMA request generation as programmed in the control registers.

23.3.0.3 Message RAM

The DCAN0 and DCAN1 enables a storage of 64 CAN messages.

23.3.0.4 Message RAM Interface

Three interface register sets control the CPU read and write accesses to the message RAM. There are two interface registers sets for read and write access, IF1 and IF2, and one interface register set for read access only, IF3. Additional information can be found in Section 23.3.8.12.

The interface registers have the same word-length as the message RAM.

23.3.0.5 Registers and Message Object Access

Data consistency is ensured by indirect accesses to the message objects. During normal operation, all CPU and DMA accesses to the message RAM are done through interface registers. In a dedicated test mode, the message RAM is memory mapped and can be directly accessed by either CPU or DMA.

23.3.0.6 Module Interface

The DCAN module registers are accessed by the CPU or user software through a 32-bit peripheral bus interface.

23.3.0.7 Dual Clock Source

Two clock domains are provided to the DCAN module: the peripheral synchronous clock domain (L3_SLOW_GCLK) and the peripheral asynchronous clock source domain (OSC0) for CAN_CLK.

Copyright © 2011, Texas Instruments Incorporated

23.3.1 CAN Operation

After hardware reset, the Init bit in the CAN control register (DCAN CTL) is set and all CAN protocol functions are disabled. The CAN module must be initialized before operating it. Figure 23-3 illustrates the basic initialization flow for the CAN module.

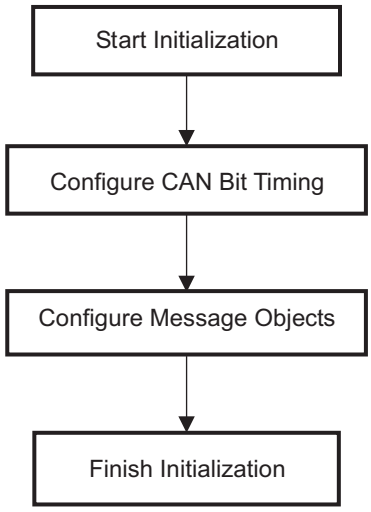
23.3.1.1 CAN Module Initialization

A general CAN module initialization would mean the following two critical steps:

- Configuration of the CAN bit timing
- Configuration of message objects

To initialize the CAN controller, the CPU has to set up the CAN bit timing and those message objects that have to be used for CAN communication. Message objects that are not needed, can be deactivated.

Figure 23-3. CAN Module General Initialization Flow



23.3.1.1.1 Configuration of CAN Bit Timing

The CAN module must be in initialization mode to configure the CAN bit timing.

For CAN bit timing software configuration flow, see Figure 23-4.

Step 1: Enter *initialization mode* by setting the Init (Initialization) bit in the CAN control register.

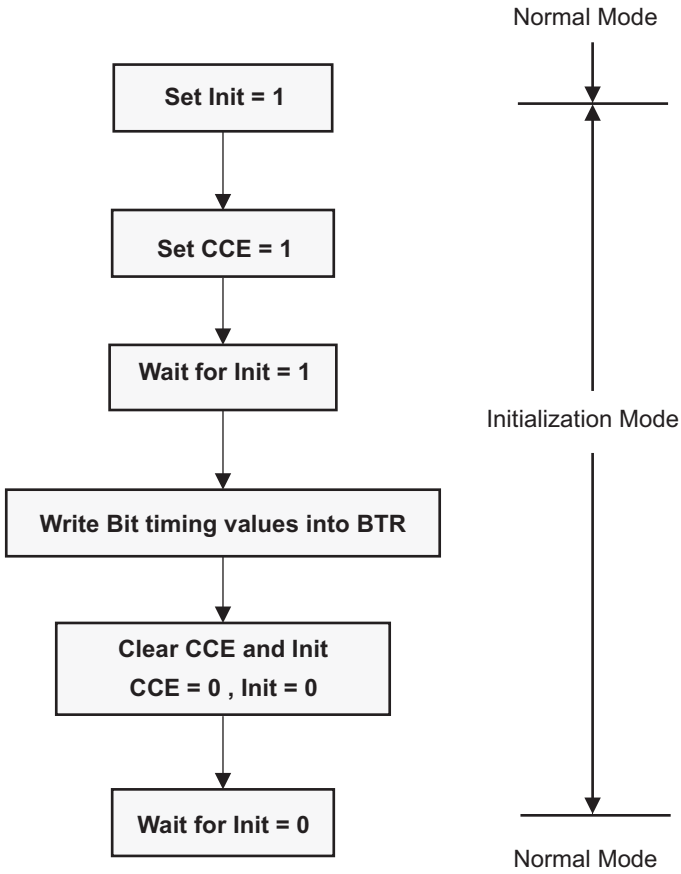
While the Init bit is set, the message transfer from and to the CAN bus is stopped, and the status of the CAN_TX output is recessive (high).

The CAN error counters are not updated. Setting the Init bit does not change any other configuration register.

Also, note that the CAN module is in initialization mode on hardware reset and during Bus-Off.

Copyright © 2011, Texas Instruments Incorporated

Figure 23-4. CAN Bit-Timing Configuration



Step 2: Set the Configure Change Enable (CCE) bit in the CAN control register.

The access to the Bit Timing register (BTR) for the configuration of the bit timing is enabled when both Init and CCE bits in the CAN Control register are set.

Step 3: Wait for the Init bit to get set. This would make sure that the module has entered *Initialization mode*.

Step 4: Write the bit timing values into the bit timing register. See Section 23.3.9.2 for the BTR value calculation for a given bit timing.

Step 5: Clear the CCE and Init bit.

Step 6: Wait for the Init bit to clear. This would ensure that the module has come out of *initialization mode*.

Following these steps, the module comes to operation by synchronizing itself to the CAN bus, provided the BTR is configured as per the CAN bus baud rate, although the message objects have to be configured before carrying out any communication.

NOTE: The module will not come out of the *initialization mode* if any incorrect BTR values are written in step 4.

NOTE: The required message objects should be configured as transmit or receive objects before the start of data transfer as explained in Section 23.3.1.1.

Copyright © 2011, Texas Instruments Incorporated

23.3.1.1.2 Configuration of Message Objects

The message objects can be configured only through the interface registers; the CPU does not have direct access to the message object (message RAM) . Familiarize yourself with the interface register set (IFx) usage (see Section 23.3.10) and the message object structure (see Section 23.3.11) before configuring the message objects.

For more information regarding the procedure to configure the message objects, see Section 23.3.7. All the message objects should be configured to particular identifiers or set to not valid before the message transfer is started. It is possible to change the configuration of message objects during normal operation (that is between data transfers).

NOTE: The message objects initialization is independent of the bit-timing configuration.

23.3.1.1.3 DCAN RAM Hardware Initialization

The memory hardware initialization for the DCAN module is enabled in the device control register, DCAN_RAMINIT, which initializes the RAM with zeros and sets parity bits accordingly. Wait for the RAMINIT_DONE bit to be set to ensure successful RAM initialization.

For more details on RAM hardware initialization, see , *Control Module*.

23.3.1.2 CAN Message Transfer (Normal Operation)

Once the DCAN is initialized and Init bit is reset to zero, the CAN core synchronizes itself to the CAN bus and is ready for message transfer as per the configured message objects.

The CPU may enable the interrupt lines (setting IE0 and IE1 to '1') at the same time when it clears Init and CCE. The status interrupts EIE and SIE may be enabled simultaneously.

The CAN communication can be carried out in any of the following two modes: interrupt and polling.

The interrupt register points to those message objects with IntPnd = '1'. It is updated even if the interrupt lines to the CPU are disabled (IE0/IE1 are zero).

The CPU may poll all MessageObject's NewDat and TxRqst bits in parallel from the NewData X registers and the Transmission Request X Registers (DCAN TXRQ X). Polling can be made easier if all transmit objects are grouped at the low numbers and all receive objects are grouped at the high numbers.

Received messages are stored into their appropriate message objects if they pass acceptance filtering.

The whole message (including all arbitration bits, DLC and up to eight data bytes) is stored into the message object. As a consequence (e.g., when the identifier mask is used), the arbitration bits which are masked to "don't care" may change in the message object when a received message is stored.

The CPU may read or write each message at any time via the interface registers, as the message handler guarantees data consistency in case of concurrent accesses.

If a permanent message object (arbitration and control bits set up during configuration and leaving unchanged for multiple CAN transfers) exists for the message, it is possible to only update the data bytes.

If several transmit messages should be assigned to one message object, the whole message object has to be configured before the transmission of this message is requested.

The transmission of multiple message objects may be requested at the same time. They are subsequently transmitted, according to their internal priority.

Messages may be updated or set to not valid at any time, even if a requested transmission is still pending. However, the data bytes will be discarded if a message is updated before a pending transmission has started.

Depending on the configuration of the message object, a transmission may be automatically requested by the reception of a remote frame with a matching identifier.

Copyright © 2011, Texas Instruments Incorporated

23.3.1.2.1 Automatic Retransmission

According to the CAN Specification (ISO11898), the DCAN provides a mechanism to automatically retransmit frames which have lost arbitration or have been disturbed by errors during transmission. The frame transmission service will not be confirmed to the user before the transmission is successfully completed.

By default, this automatic retransmission is enabled. It can be disabled by setting bit disable automatic retransmission (DAR) in the CAN Control register. Further details to this mode are provided in Section 23.3.8.3.

23.3.1.2.2 Auto-Bus-On

By default, after the DCAN has entered Bus-Off state, the CPU can start a Bus-Off-Recovery sequence by resetting the Init bit. If this is not done, the module will stay in Bus-Off state.

The DCAN provides an automatic Auto-Bus-On feature which is enabled by bit ABO in the CAN control register. If set, the DCAN will automatically start the Bus-Off-Recovery sequence. The sequence can be delayed by a user-defined number of L3_SLOW_GCLK cycles which can be defined in the Auto-Bus-On Time register (DCAN ABOTR).

NOTE: If the DCAN goes to Bus-Off state due to a massive occurrence of CAN bus errors, it stops all bus activities and automatically sets the Init bit. Once the Init bit has been reset by the CPU or due to the Auto-Bus-On feature, the device will wait for 129 occurrences of bus Idle (equal to 129 * 11 consecutive recessive bits) before resuming normal operation. At the end of the Bus-Off recovery sequence, the error counters will be reset.

23.3.1.3 Test Modes

The DCAN module provides several test modes which are mainly intended for production tests or self test.

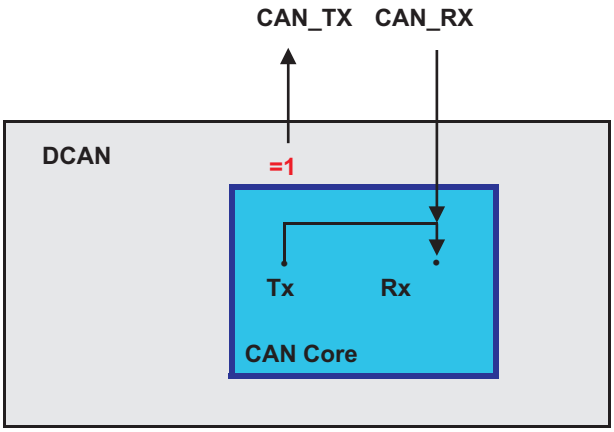
For all test modes, the Test bit in the CAN control register needs to be set to one. This enables write access to the test register (DCAN TEST).

23.3.1.3.1 Silent Mode

The silent mode may be used to analyze the traffic on the CAN bus without affecting it by sending dominant bits (e.g., acknowledge bit, overload flag, active error flag). The DCAN is still able to receive valid data frames and valid remote frames, but it will not send any dominant bits. However, these are internally routed to the CAN core.

Figure 23-5 shows the connection of signals CAN_TX and CAN_RX to the CAN core in silent mode. Silent mode can be activated by setting the Silent bit in the Test register to one. In ISO 11898-1, the silent mode is called the bus monitoring mode.

Figure 23-5. CAN Core in Silent Mode



Copyright © 2011, Texas Instruments Incorporated

23.3.1.3.2 Loopback Mode

The loopback mode is mainly intended for hardware self-test functions. In this mode, the CAN core uses internal feedback from Tx output to Rx input. Transmitted messages are treated as received messages, and can be stored into message objects if they pass acceptance filtering. The actual value of the CAN_RX input pin is disregarded by the CAN core. Transmitted messages can still be monitored at the CAN_TX pin.

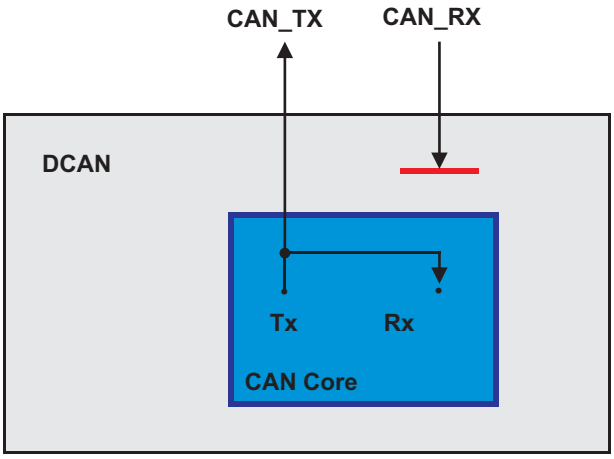
In order to be independent from external stimulation, the CAN core ignores acknowledge sampled in the acknowledge slot of a data/remote frame.

Figure 23-6 shows the connection of signals CAN_TX and CAN_RX to the CAN core in loopback mode.

Loopback mode can be activated by setting bit LBack in the test register to one.

NOTE: In loopback mode, the signal path from CAN core to Tx pin, the Tx pin itself, and the signal path from Tx pin back to CAN core are disregarded. For including these into the testing, see Section 23.3.1.3.3.

Figure 23-6. CAN Core in Loopback Mode



Copyright © 2011, Texas Instruments Incorporated

23.3.1.3.3 External Loopback Mode

The external loopback mode is similar to the loopback mode; however, it includes the signal path from CAN core to Tx pin, the Tx pin itself, and the signal path from Tx pin back to CAN core. When external loopback mode is selected, the input of the CAN core is connected to the input buffer of the Tx pin.

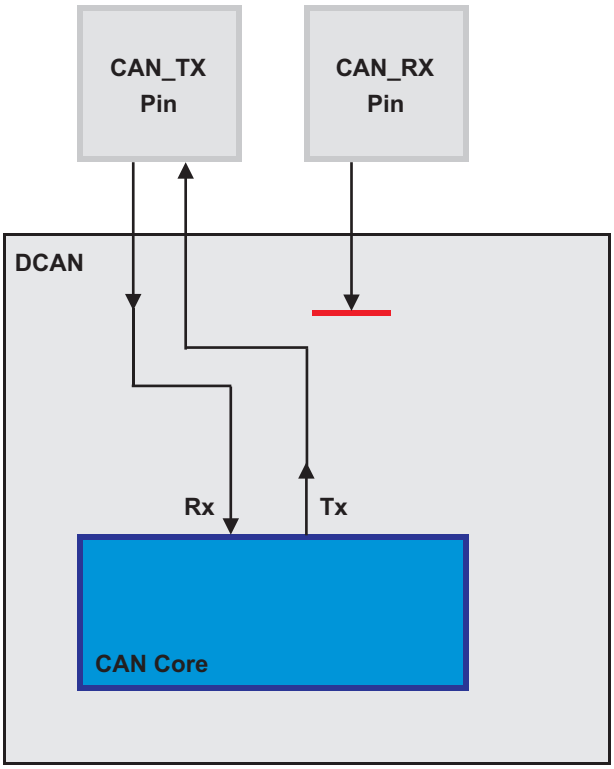
With this configuration, the Tx pin IO circuit can be tested.

External loopback mode can be activated by setting bit **ExL** in test register to one.

Figure 23-7 shows the connection of signals CAN_TX and CAN_RX to the CAN core in external loopback mode.

NOTE: When loopback mode is active (LBack bit set), the ExL bit will be ignored.

Figure 23-7. CAN Core in External Loopback Mode



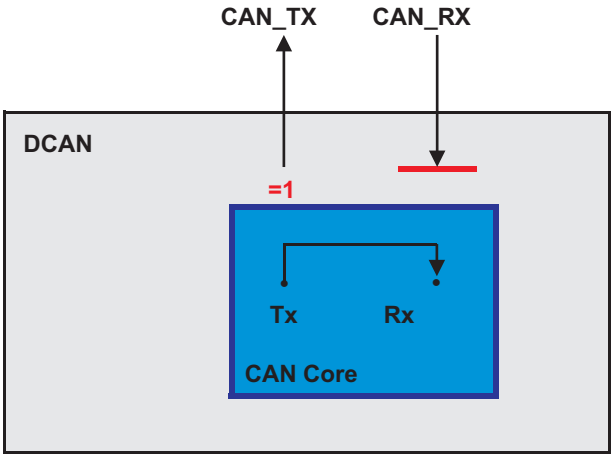
23.3.1.3.4 Loopback Mode Combined With Silent Mode

It is also possible to combine loopback mode and silent mode by setting bits LBack and Silent at the same time. This mode can be used for a “Hot Selftest,” i.e., the DCAN hardware can be tested without affecting the CAN network. In this mode, the CAN_RX pin is disconnected from the CAN core and no dominant bits will be sent on the CAN_TX pin.

Figure 23-8 shows the connection of the signals CAN_TX and CAN_RX to the CAN core in case of the combination of loopback mode with silent mode.

Copyright © 2011, Texas Instruments Incorporated

Figure 23-8. CAN Core in Loop Back Combined With Silent Mode



23.3.1.3.5 Software Control of CAN_TX pin

Four output functions are available for the CAN transmit pin CAN_TX. In addition to its default function (serial data output), the CAN_TX pin can drive constant dominant or recessive values, or it can drive the CAN sample point signal to monitor the CAN core's bit timing.

Combined with the readable value of the CAN_RX pin, this function can be used to check the physical layer of the CAN bus.

The output mode of pin CAN_TX is selected by programming the test register bits Tx[1:0] as described in section Section 23.4.6.

NOTE: The software control for the CAN_TX pin interferes with CAN protocol functions. For CAN message transfer or any of the test modes (loopback mode, external loopback mode or silent mode), the CAN_TX pin should operate in its default functionality.

23.3.2 Dual Clock Source

Two clock domains are provided to the DCAN module: the peripheral synchronous clock domain (L3_SLOW_GCLK) as the general module clock source, and the peripheral asynchronous clock source domain (OSC0) provided to the CAN core (as clock source CAN_CLK) for generating the CAN bit timing.

Both clock domains can be derived from the same clock source (so that L3_SLOW_GCLK = OSC0).

For more information on how to configure the relevant clock source registers in the system module, see Chapter 8, Power and Clock Management.

Between the two clock domains, a synchronization mechanism is implemented in the DCAN module in order to ensure correct data transfer.

NOTE: If the dual clock functionality is used, then L3_SLOW_GCLK must always be higher or equal to CAN_CLK (OSC0) (derived from the asynchronous clock source), in order to achieve a stable functionality of the DCAN. Here also the frequency shift of the modulated L3_SLOW_GCLK has to be considered:

$f_{0,\ L3_SLOW_GCLK}(OCP) \pm \Delta f_{FM,\ L3_SLOW_GCLK}(OCP) \geq f_{CANCLK}$

NOTE: The CAN core has to be programmed to at least 8 clock cycles per bit time. To achieve a transfer rate of 1 MBaud when using the asynchronous clock domain as the clock source for CAN_CLK (OSC0), an oscillator frequency of 8MHz or higher has to be used.

Copyright © 2011, Texas Instruments Incorporated

23.3.3 Interrupt Functionality

Interrupts can be generated on two interrupt lines: DCANINT0 and DCANINT1. These lines can be enabled by setting the IE0 and IE1 bits, respectively, in the CAN control register. The interrupts are level triggered at the chip level.

The DCAN provides three groups of interrupt sources: message object interrupts, status change interrupts, and error interrupts (see Figure 23-9 and Figure 23-10).

The source of an interrupt can be determined by the interrupt identifiers Int0ID/Int1ID in the interrupt register (see Section 23.4.5). When no interrupt is pending, the register will hold the value zero.

Each interrupt line remains active until the dedicated field in the interrupt register DCAN INT (Int0ID / Int1ID) again reach zero (this means the cause of the interrupt is reset), or until IE0 / IE1 are reset.

The value 0x8000 in the Int0ID field indicates that an interrupt is pending because the CAN core has updated (not necessarily changed) the Error and Status register (DCAN ES and PARITYERR_EOI). This interrupt has the highest priority. The CPU can update (reset) the status bits WakeUpPnd, RxOk, TxOk and LEC by reading the error and status register DCAN ES, but a write access of the CPU will never generate or reset an interrupt.

Values between 1 and the number of the last message object indicates that the source of the interrupt is one of the message objects, Int0ID resp. Int1ID will point to the pending message interrupt with the highest priority. The Message Object 1 has the highest priority; the last message object has the lowest priority.

An interrupt service routine that reads the message that is the source of the interrupt may read the message and reset the message object's IntPnd at the same time (ClrIntPnd bit in the IF1/IF2 command register). When IntPnd is cleared, the interrupt register will point to the next message object with a pending interrupt.

23.3.3.1 Message Object Interrupts

Message object interrupts are generated by events from the message objects. They are controlled by the flags IntPND, TxIE and RxIE that are described in Section 23.3.11.1.

Message object interrupts can be routed to either DCANINT0 or DCANINT1 line, controlled by the interrupt multiplexer register (DCAN INTMUX12 to DCAN INTMUX78), see Section 23.4.17.

23.3.3.2 Status Change Interrupts

The events WakeUpPnd, RxOk, TxOk and LEC in error and status register (DCAN ES) belong to the status change interrupts. The status change interrupt group can be enabled by bit in CAN control register.

If SIE is set, a status change interrupt will be generated at each CAN frame, independent of bus errors or valid CAN communication, and also independent of the message RAM configuration.

Status change interrupts can only be routed to interrupt line DCAN0INT, which has to be enabled by setting IE0 in the CAN control register.

NOTE: Reading the error and status register will clear the WakeUpPnd flag. If in global power-down mode, the WakeUpPnd flag is cleared by such a read access before the DCAN module has been waken up by the system, the DCAN may re-assert the WakeUpPnd flag, and a second interrupt may occur.

23.3.3.3 Error Interrupts

The events PER, BOff and EWarn, monitored in the Error and Status register, DCAN ES, belong to the error interrupts. The error interrupt group can be enabled by setting bit EIE in the CAN Control register.

Error interrupts can only be routed to interrupt line DCAN0INT, which has to be enabled by setting IE0 in the CAN Control register.

23.3.4 Local Power-Down Mode

The DCAN supports a local power-down mode, which can be controlled within the DCAN control registers.

23.3.4.1 Entering Local Power-Down Mode

The local power-down mode is requested by setting the PDR bit in CAN Control register.

The DCAN then finishes all transmit requests of the message objects. When all requests are done, DCAN waits until a bus idle state is recognized. Then it will automatically set the Init bit in CAN control register to prevent any further CAN transfers, and it will also set the PDA bit in CAN error and status register. With setting the PDA bits, the DCAN module indicates that the local power-down mode has been entered.

During local power-down mode, the internal clocks of the DCAN module are turned off, but there is a wakeup logic (see Section 23.3.4.2) that can be active, if enabled. Also, the actual contents of the control registers can be read back.

NOTE: In local low-power mode, the application should not clear the Init bit while PDR is set. If there are any messages in the message RAM which are configured as transmit messages and the application resets the init bit, these messages may get sent.

23.3.4.2 Wakeup From Local Power Down

There are two ways to wake up the DCAN from local power-down mode:

- The application could wake up the DCAN module manually by clearing the PDR bit and then clearing the Init bit in CAN Control register.
- Alternatively, a CAN bus activity detection circuit can be activated by setting the wakeup on bus activity bit (WUBA) in the CAN control register. If this circuit is active, on occurrence of a dominant CAN bus level, the DCAN will automatically start the wakeup sequence. It will clear the PDR bit in the CAN Control register and also clear the PDA bit in the error and status register. The WakeUpPnd bit in CAN error and status register will be set. If status interrupts are enabled, also an interrupt will be generated. Finally the Init bit in CAN control register will be cleared.

After the Init bit has been cleared, the module waits until it detects 11 consecutive recessive bits on the CAN_RX pin and then goes bus-active again.

NOTE: The CAN transceiver circuit has to stay active in order to detect any CAN bus activity while the DCAN is in local power down mode. The first CAN message, which initiates the bus activity, cannot be received. This means that the first message received in power-down and automatic wake-up mode, is lost.

Figure 23-11 shows a flow diagram about entering and leaving local power-down mode.

Copyright © 2011, Texas Instruments Incorporated

Figure 23-11. Local Power-Down Mode Flow Diagram

23.3.5 Parity Check Mechanism

The DCAN provides a parity check mechanism to ensure data integrity of message RAM data. For each word (32 bits) in message RAM, one parity bit will be calculated. The formation of the different words is according to the message RAM representation in RDA mode, see Section 23.3.11.4.

Parity information is stored in the message RAM on write accesses and will be checked against the stored parity bit from message RAM on read accesses.

The Parity check functionality can be enabled or disabled by PMD bit field in the CAN control register.

In case of disabled parity check, the parity bits in message RAM will be left unchanged on write access to data area and no check will be done on read access.

If parity checking is enabled, parity bits will be automatically generated and checked by the DCAN. The parity bits could be read in debug/suspend mode (see Section 23.3.11.3) or in RDA mode (see Section 23.3.11.4). However, direct write access to the parity bits is only possible in these two modes with parity check disabled.

A parity bit will be set, if the modulo-2-sum of the data bits is 1. This definition is equivalent to: The parity bit will be set, if the number of 1 bits in the data is odd.

NOTE: The parity scheme is tied to even parity at the device level.

23.3.5.1 Behavior on Parity Error

On any read access to message RAM (e.g., during start of a CAN frame transmission), the parity of the message object will be checked. If a parity error is detected, the PER bit in the error and status register will be set. If error interrupts are enabled, an interrupt would also be generated. In order to avoid the transmission of invalid data over the CAN bus, the D bit of the message object will be reset.

The message object data can be read by the host CPU, independently of parity errors. Thus, the application has to ensure that the read data is valid, e.g., by immediately checking the parity error code register (DCAN PERR) on parity error interrupt.

NOTE: During RAM initialization, no parity check will be done.

23.3.5.2 Parity Testing

Testing the parity mechanism can be done by enabling the bit RamDirectAccess (RDA) and manually writing the parity bits directly to the dedicated RAM locations. With this, data and parity bits could be checked when reading directly from RAM.

NOTE: If parity check was disabled, the application has to ensure correct parity bit handling in order to prevent parity errors later on when parity check is enabled.

Copyright © 2011, Texas Instruments Incorporated

23.3.6 Debug/Suspend Mode

The module supports the usage of an external debug unit by providing functions like pausing DCAN activities and making message RAM content accessible via OCP interface.

Before entering debug/suspend mode, the circuit will either wait until a started transmission or reception will be finished and bus idle state is recognized, or immediately interrupt a current transmission or reception. This is depending on bit IDS in the CAN control register.

Afterwards, the DCAN enters debug/suspend mode, indicated by InitDbg flag in the CAN control register.

During debug/suspend mode, all DCAN registers can be accessed. Reading reserved bits will return '0'. Writing to reserved bits will have no effect.

Also, the message RAM will be memory mapped. This allows the external debug unit to read the message RAM. For the memory organization, see Section 23.3.11.3).

NOTE: During debug/suspend mode, the message RAM cannot be accessed via the IFx register sets.

NOTE: Writing to control registers in debug/suspend mode may influence the CAN state machine and further message handling.

For debug support, the auto clear functionality of the following DCAN registers is disabled:

- Error and status register (clear of status flags by read)
- IF1/IF2 command registers (clear of DMAActive flag by read/write)

23.3.7 Configuration of Message Objects

The whole message RAM should be configured before the end of the initialization, however it is also possible to change the configuration of message objects during CAN communication.

The CAN software driver library should offer subroutines that:

- Transfer a complete message structure into a message object. (Configuration)
- Transfer the data bytes of a message into a message object and set TxRqst and NewDat. (Start a new transmission)
- Get the data bytes of a message from a message object and clear NewDat (and IntPnd). (Read received data)
- Get the complete message from a message object and clear NewDat (and IntPnd). (Read a received message, including identifier, from a message object with UMask = '1')

Parameters of the subroutines are the Message Number and a pointer to a complete message structure or to the data bytes of a message structure.

Two examples of assigning the IFx interface register sets to these subroutines are shown here:

In the first method, the tasks of the application program that may access the module are divided into two groups. Each group is restricted to the use of one of the interface register sets. The tasks of one group may interrupt tasks of the other group, but not of the same group.

In the second method, which may be a special case of the first method, there are only two tasks in the application program that access the module. A Read_Message task that uses IF2 or IF3 to get received messages from the message RAM and a Write_Message task that uses IF1 to write messages to be transmitted (or to be configured) into the message RAM. Both tasks may interrupt each other.

Copyright © 2011, Texas Instruments Incorporated

23.3.7.1 Configuration of a Transmit Object for Data Frames

Table 23-4 shows how a transmit object can be initialized.

Table 23-4. Initialization of a Transmit Object

MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
1	appl.	appl.	appl.	1	1	0	0	0	appl.	0	appl.	0

The arbitration bits (ID[28:0] and Xtd bit) are given by the application. They define the identifier and type of the outgoing message. If an 11-bit identifier (standard frame) is used (Xtd = '0'), it is programmed to ID[28:18]. In this case, ID[17:0] can be ignored.

The data registers (DLC[3:0] and Data0-7) are given by the application. TxRqst and RmtEn should not be set before the data is valid.

If the TxIE bit is set, the IntPnd bit will be set after a successful transmission of the message object.

If the RmtEn bit is set, a matching received remote frame will cause the TxRqst bit to be set; the remote frame will autonomously be answered by a data frame.

The mask bits (Msk[28:0], UMask, MXtd, and MDir bits) may be used (UMask='1') to allow groups of remote frames with similar identifiers to set the TxRqst bit. The Dir bit should not be masked. For details, see Section 23.3.8.8. Identifier masking must be disabled (UMask = '0') if no remote frames are allowed to set the TxRqst bit (RmtEn = '0').

23.3.7.2 Configuration of a Transmit Object for Remote Frames

It is not necessary to configure transmit objects for the transmission of remote frames. Setting TxRqst for a receive object causes the transmission of a remote frame with the same identifier as the data frame for which this receive object is configured.

23.3.7.3 Configuration of a Single Receive Object for Data Frames

Table 23-5 shows how a receive object for data frames can be initialized.

Table 23-5. Initialization of a single Receive Object for Data Frames

MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
1	appl.	appl.	appl.	1	0	0	0	appl.	0	0	0	0

The arbitration bits (ID[28:0] and Xtd bit) are given by the application. They define the identifier and type of accepted received messages. If an 11-bit Identifier (standard frame) is used (Xtd = '0'), it is programmed to ID[28:18]. In this case, ID[17:0] can be ignored. When a data frame with an 11-bit Identifier is received, ID[17:0] is set to '0'.

The data length code (DLC[3:0]) is given by the application. When the message handler stores a data frame in the message object, it will store the received data length code and eight data bytes. If the data length code is less than 8, the remaining bytes of the message object may be overwritten by non specified values.

The mask bits (Msk[28:0], UMask, MXtd, and MDir bits) may be used (UMask = '1') to allow groups of data frames with similar identifiers to be accepted. The Dir bit should not be masked in typical applications. If some bits of the mask bits are set to "don't care," the corresponding bits of the arbitration register will be overwritten by the bits of the stored data frame.

If the RxIE bit is set, the IntPnd bit will be set when a received data frame is accepted and stored in the message object.

If the TxRqst bit is set, the transmission of a remote frame with the same identifier as actually stored in the arbitration bits will be triggered. The content of the arbitration bits may change if the mask bits are used (UMask = '1') for acceptance filtering.

Copyright © 2011, Texas Instruments Incorporated

23.3.7.4 Configuration of a Single Receive Object for Remote Frames

Table 23-6 shows how a receive object for remote frames can be initialized.

Table 23-6. Initialization of a Single Receive Object for Remote Frames

MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
1	appl.	appl.	appl.	1	1	0	0	appl.	0	0	0	0

A receive object for remote frames may be used to monitor remote frames on the CAN bus. The remote frame stored in the receive object will not trigger the transmission of a data frame. Receive objects for remote frames may be expanded to a FIFO buffer (see Section 23.3.7.5).

UMask must be set to '1.' The mask bits (Msk[28:0], UMask, MXtd, and MDir bits) may be set to "must-match" or to "don't care," to allow groups of remote frames with similar identifiers to be accepted. The Dir bit should not be masked in typical applications. For details, see Section 23.3.8.8.

The arbitration bits (ID[28:0] and Xtd bit) may be given by the application. They define the identifier and type of accepted received remote frames. If some bits of the mask bits are set to "don't care," the corresponding bits of the arbitration bits will be overwritten by the bits of the stored remote frame. If an 11-bit Identifier (standard frame) is used (Xtd = '0'), it is programmed to ID[28:18]. In this case, ID[17:0] can be ignored. When a remote frame with an 11-bit Identifier is received, ID[17:0] will be set to '0.'

The data length code (DLC[3:0]) may be given by the application. When the message handler stores a remote frame in the message object, it will store the received data length code. The data bytes of the message object will remain unchanged.

If the RxIE bit is set, the IntPnd bit will be set when a received remote frame is accepted and stored in the message object.

23.3.7.5 Configuration of a FIFO Buffer

With the exception of the EoB bit, the configuration of receive objects belonging to a FIFO buffer is the same as the configuration of a single receive object.

To concatenate multiple message objects to a FIFO buffer, the identifiers and masks (if used) of these message objects have to be programmed to matching values. Due to the implicit priority of the message objects, the message object with the lowest number will be the first message object of the FIFO buffer. The EoB bit of all message objects of a FIFO buffer except the last one have to be programmed to zero. The EoB bits of the last message object of a FIFO Buffer is set to one, configuring it as the end of the block.

Copyright © 2011, Texas Instruments Incorporated

23.3.8 Message Handling

When initialization is finished, the DCAN module synchronizes itself to the traffic on the CAN bus. It does acceptance filtering on received messages and stores those frames that are accepted into the designated message objects. The application has to update the data of the messages to be transmitted and to enable and request their transmission. The transmission is requested automatically when a matching remote frame is received.

The application may read messages which are received and accepted. Messages that are not read before the next messages is accepted for the same message object will be overwritten.

Messages may be read interrupt-driven or after polling of NewDat.

23.3.8.1 Message Handler Overview

The message handler state machine controls the data transfer between the Rx/Tx shift register of the CAN core and the message RAM. It performs the following tasks:

- Data transfer from message RAM to CAN core (messages to be transmitted)
- Data transfer from CAN core to the message RAM (received messages)
- Data transfer from CAN core to the acceptance filtering unit
- Scanning of message RAM for a matching message object (acceptance filtering)
- Scanning the same message object after being changed by IF1/IF2 registers when priority is the same or higher as the message the object found by last scanning
- Handling of TxRqst flags
- Handling of interrupt flags

The message handler registers contains status flags of all message objects grouped into the following topics:

- Transmission Request Flags
- New Data Flags
- Interrupt Pending Flags
- Message Valid Registers

Instead of collecting above listed status information of each message object via IFx registers separately, these message handler registers provides a fast and easy way to get an overview, for example, about all pending transmission requests.

All message handler registers are read-only.

23.3.8.2 Receive/Transmit Priority

The receive/transmit priority for the message objects is attached to the message number, not to the CAN identifier. Message object 1 has the highest priority, while the last implemented message object has the lowest priority. If more than one transmission request is pending, they are serviced due to the priority of the corresponding message object so messages with the highest priority, for example, can be placed in the message objects with the lowest numbers.

The acceptance filtering for received data frames or remote frames is also done in ascending order of message objects, so a frame that has been accepted by a message object cannot be accepted by another message object with a higher message number. The last message object may be configured to accept any data frame or remote frame that was not accepted by any other message object, for nodes that need to log the complete message traffic on the CAN bus.

23.3.8.3 Transmission of Messages in Event-Driven CAN Communication

If the shift register of the CAN core is ready for loading and if there is no data transfer between the IFx registers and message RAM, the D bits in the Message Valid register (DCAN MSGVAL12 to DCAN MSGVAL78) and the TxRqst bits in the transmission request register are evaluated. The valid message object with the highest priority pending transmission request is loaded into the shift register by the message handler and the transmission is started. The message object's NewDat bit is reset.

Copyright © 2011, Texas Instruments Incorporated

After a successful transmission and if no new data was written to the message object (NewDat = '0') since the start of the transmission, the TxRqst bit will be reset. If TxIE is set, IntPnd will be set after a successful transmission. If the DCAN has lost the arbitration or if an error occurred during the transmission, the message will be retransmitted as soon as the CAN bus is free again. If meanwhile the transmission of a message with higher priority has been requested, the messages will be transmitted in the order of their priority.

If automatic retransmission mode is disabled by setting the DAR bit in the CAN control register, the behavior of bits TxRqst and NewDat in the Message Control register of the interface register set is as follows:

- When a transmission starts, the TxRqst bit of the respective interface register set is reset, while bit NewDat remains set.
- When the transmission has been successfully completed, the NewDat bit is reset.

When a transmission failed (lost arbitration or error) bit NewDat remains set. To restart the transmission, the application has to set TxRqst again.

Received remote frames do not require a receive object. They will automatically trigger the transmission of a data frame, if in the matching transmit object the RmtEn bit is set.

23.3.8.4 Updating a Transmit Object

The CPU may update the data bytes of a transmit object any time via the IF1/IF2 interface registers, neither D nor TxRqst have to be reset before the update.

Even if only part of the data bytes is to be updated, all four bytes in the corresponding IF1/IF2 Data A register (DCAN IF1DATA/DCAN IF2DATA) or IF1/IF2 Data B register (DCAN IF1DATB/DCAN IF2DATB) have to be valid before the content of that register is transferred to the message object. Either the CPU has to write all four bytes into the IF1/IF2 data register or the message object is transferred to the IF1/IF2 data register before the CPU writes the new data bytes.

When only the data bytes are updated, first 0x87 can be written to bits [23:16] of the IF1/IF2 Command register (DCAN IF1CMD/DCAN IF2CMD) and then the number of the message object is written to bits [7:0] of the command register, concurrently updating the data bytes and setting TxRqst with NewDat.

To prevent the reset of TxRqst at the end of a transmission that may already be in progress while the data is updated, NewDat has to be set together with TxRqst in event driven CAN communication. For details, see Section 23.3.8.3.

When NewDat is set together with TxRqst, NewDat will be reset as soon as the new transmission has started.

23.3.8.5 Changing a Transmit Object

If the number of implemented message objects is not sufficient to be used as permanent message objects only, the transmit objects may be managed dynamically. The CPU can write the whole message (arbitration, control, and data) into the interface register. The bits [23:16] of the command register can be set to 0xB7 for the transfer of the whole message object content into the message object. Neither D nor TxRqst have to be reset before this operation.

If a previously requested transmission of this message object is not completed but already in progress, it will be continued; however, it will not be repeated if it is disturbed.

To only update the data bytes of a message to be transmitted, bits [23:16] of the command register should be set to 0x87.

NOTE: After the update of the transmit object, the interface register set will contain a copy of the actual contents of the object, including the part that had not been updated.

Copyright © 2011, Texas Instruments Incorporated

23.3.8.6 Acceptance Filtering of Received Messages

When the arbitration and control bits (Identifier + IDE + RTR + DLC) of an incoming message are completely shifted into the shift register of the CAN core, the message handler starts the scan of the message RAM for a matching valid message object:

- The acceptance filtering unit is loaded with the arbitration bits from the CAN core shift register.
- Then the arbitration and mask bits (including MsgVal, UMask, NewDat, and EoB) of message object 1 are loaded into the acceptance filtering unit and are compared with the arbitration bits from the shift register. This is repeated for all following message objects until a matching message object is found, or until the end of the message RAM is reached.
- If a match occurs, the scanning is stopped and the message handler proceeds depending on the type of the frame (data frame or remote frame) received.

23.3.8.7 Reception of Data Frames

The message handler stores the message from the CAN core shift register into the respective message object in the message RAM. Not only the data bytes, but all arbitration bits and the data length code are stored into the corresponding message object. This ensures that the data bytes stay associated to the identifier even if arbitration mask registers are used.

The NewDat bit is set to indicate that new data (not yet seen by the CPU) has been received. The CPU should reset the NewDat bit when it reads the message object. If at the time of the reception the NewDat bit was already set, MsgLst is set to indicate that the previous data (supposedly not seen by the CPU) is lost. If the RxIE bit is set, the IntPnd bit is set, causing the interrupt register to point to this message object.

The TxRqst bit of this message object is reset to prevent the transmission of a remote frame, while the requested data frame has just been received.

23.3.8.8 Reception of Remote Frames

When a remote frame is received, three different configurations of the matching message object have to be considered:

- Dir = ‘1’ (direction = transmit), RmtEn = ‘1’, UMask = ‘1’ or ‘0’

  The TxRqst bit of this message object is set at the reception of a matching remote frame. The rest of the message object remains unchanged.
- Dir = ‘1’ (direction = transmit), RmtEn = ‘0’, UMask = ‘0’

  The remote frame is ignored, this message object remains unchanged.
- Dir = ‘1’ (direction = transmit), RmtEn = ‘0’, UMask = ‘1’

  The remote frame is treated similar to a received data frame. At the reception of a matching Remote Message Frame, the TxRqst bit of this message object is reset. The arbitration and control bits (Identifier + IDE + RTR + DLC) from the shift register are stored in the message object in the message RAM and the NewDat bit of this message object is set. The data bytes of the message object remain unchanged.

23.3.8.9 Reading Received Messages

The CPU may read a received message any time via the IFx interface register. The data consistency is guaranteed by the message handler state machine. Typically the CPU will write first 0x7F to bits [23:16] and then the number of the message object to bits [7:0] of the command register. That combination will transfer the entire received message from the message RAM into the interface register set. Additionally, the bits NewDat and IntPnd are cleared in the message RAM (not in the interface register set). The values of these bits in the message control register always reflect the status before resetting the bits. If the message object uses masks for acceptance filtering, the arbitration bits show which of the different matching messages has been received.

The actual value of NewDat shows whether a new message has been received since last time when this message object was read. The actual value of MsgLst shows whether more than one message has been received since the last time when this message object was read. MsgLst will not be automatically reset.

Copyright © 2011, Texas Instruments Incorporated

23.3.8.10 Requesting New Data for a Receive Object

By means of a remote frame, the CPU may request another CAN node to provide new data for a receive object. Setting the TxRqst bit of a receive object will cause the transmission of a remote frame with the identifier of the receive object. This remote frame triggers the other CAN node to start the transmission of the matching data frame. If the matching data frame is received before the remote frame could be transmitted, the TxRqst bit is automatically reset. Setting the TxRqst bit without changing the contents of a message object requires the value 0x84 in bits [23:16] of the command register.

23.3.8.11 Storing Received Messages in FIFO Buffers

Several message objects may be grouped to form one or more FIFO buffers. Each FIFO buffer configured to store received messages with a particular (group of) identifier(s). Arbitration and mask registers of the FIFO buffer's message objects are identical. The end of buffer (EoB) bits of all but the last of the FIFO buffer's message objects are '0'; in the last one the EoB bit is '1.'

Received messages with identifiers matching to a FIFO buffer are stored into a message object of this FIFO buffer, starting with the message object with the lowest message number. When a message is stored into a message object of a FIFO buffer, the NewDat bit of this message object is set. By setting NewDat while EoB is '0', the message object is locked for further write accesses by the message handler until the CPU has cleared the NewDat bit.

Messages are stored into a FIFO buffer until the last message object of this FIFO buffer is reached. If none of the preceding message objects is released by writing NewDat to '0,' all further messages for this FIFO buffer will be written into the last message object of the FIFO buffer (EoB = '1') and therefore overwrite previous messages in this message object.

23.3.8.12 Reading From a FIFO Buffer

Several messages may be accumulated in a set of message objects which are concatenated to form a FIFO buffer before the application program is required (in order to avoid the loss of data) to empty the buffer.

A FIFO buffer of length N will store –1 plus the last received message since last time it was cleared.

A FIFO buffer is cleared by reading and resetting the NewDat bits of all its message objects, starting at the FIFO Object with the lowest message number. This should be done in a subroutine following the example shown in Figure 23-12.

NOTE: All message objects of a FIFO buffer need to be read and cleared before the next batch of messages can be stored. Otherwise, true FIFO functionality can not be guaranteed, since the message objects of a partly read buffer will be re-filled according to the normal (descending) priority.

Reading from a FIFO buffer message object and resetting its NewDat bit is handled the same way as reading from a single message object.

23.3.9 CAN Bit Timing

The DCAN supports bit rates between less than 1 kBit/s and 1000 kBit/s.

Each member of the CAN network has its own clock generator, typically derived from a crystal oscillator. The bit timing parameters can be configured individually for each CAN node, creating a common bit rate even though the CAN nodes' oscillator periods (f_{osc}) may be different.

The frequencies of these oscillators are not absolutely stable. Small variations are caused by changes in temperature or voltage and by deteriorating components. As long as the variations remain inside a specific oscillator tolerance range (df), the CAN nodes are able to compensate for the different bit rates by resynchronizing to the bit stream.

In many cases, the CAN bit synchronization will amend a faulty configuration of the CAN bit timing to such a degree that only occasionally an error frame is generated. In the case of arbitration however, when two or more CAN nodes simultaneously try to transmit a frame, a misplaced sample point may cause one of the transmitters to become error passive.

The analysis of such sporadic errors requires a detailed knowledge of the CAN bit synchronization inside a CAN node and of the CAN nodes' interaction on the CAN bus.

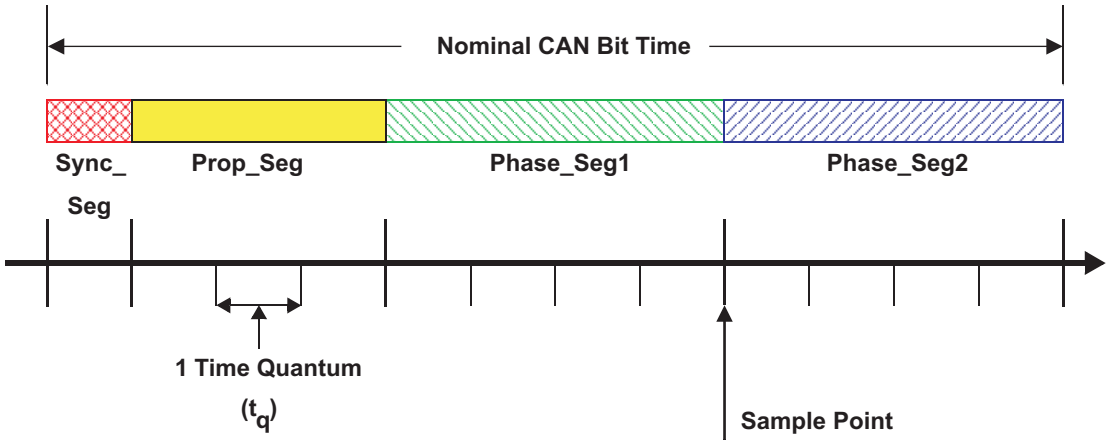
Even if minor errors in the configuration of the CAN bit timing do not result in immediate failure, the performance of a CAN network can be reduced significantly.

23.3.9.1 Bit Time and Bit Rate

According to the CAN specification, the bit time is divided into four segments (see Figure 23-13):

- Synchronization segment (Sync_Seg)
- Propagation time segment (Prop_Seg)
- Phase buffer segment 1 (Phase_Seg1)
- Phase buffer segment 2 (Phase_Seg2)

Figure 23-13. Bit Timing



Each segment consists of a specific number of time quanta. The length of one time quantum (t_q), which is the basic time unit of the bit time, is given by the CAN_CLK and the baud rate prescalers (BRPE and BRP). With these two baud rate prescalers combined, divider values from 1 to 1024 can be programmed:

t_q = Baud Rate Prescaler / CAN_CLK

Apart from the fixed length of the synchronization segment, these numbers are programmable. Table 23-7 describes the minimum programmable ranges required by the CAN protocol.

A given bit rate may be met by different bit time configurations.

Copyright © 2011, Texas Instruments Incorporated

Table 23-7. Parameters of the CAN Bit Time

Parameter	Range	Remark
Sync_Seg	1 t_q (fixed)	Synchronization of bus input to CAN_CLK
Prop_Seg	[1 … 8] t_q	Compensates for the physical delay times
Phase_Seg1	[1 … 8] t_q	May be lengthened temporarily by synchronization
Phase_Seg2	[1 … 8] t_q	May be shortened temporarily by synchronization
Synchronization Jump Width (SJW)	[1 … 4] t_q	May not be longer than either Phase Buffer Segment

NOTE: For proper functionality of the CAN network, the physical delay times and the oscillator's tolerance range have to be considered.

23.3.9.1.1 Synchronization Segment

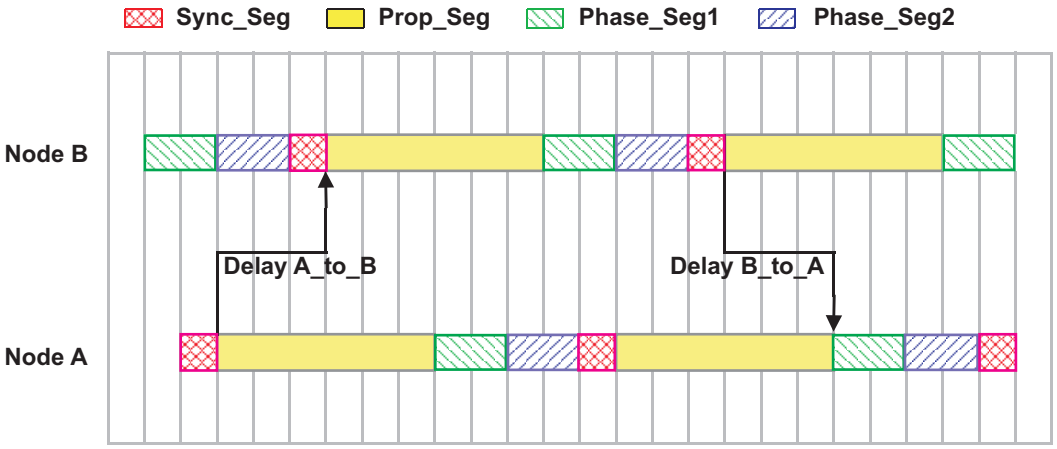
The synchronization segment (Sync_Seg) is the part of the bit time where edges of the CAN bus level are expected to occur. If an edge occurs outside of Sync_Seg, its distance to the Sync_Seg is called the phase error of this edge.

23.3.9.1.2 Propagation Time Segment

This part of the bit time is used to compensate physical delay times within the CAN network. These delay times consist of the signal propagation time on the bus and the internal delay time of the CAN nodes.

Any CAN node synchronized to the bit stream on the CAN bus can be out of phase with the transmitter of the bit stream, caused by the signal propagation time between the two nodes. The CAN protocol's nondestructive bitwise arbitration and the dominant acknowledge bit provided by receivers of CAN messages require that a CAN node transmitting a bit stream must also be able to receive dominant bits transmitted by other CAN nodes that are synchronized to that bit stream. The example in Figure 23-14 shows the phase shift and propagation times between two CAN nodes.

Figure 23-14. The Propagation Time Segment



Delay A_to_B >= node output delay(A) + bus line delay(AÆB) + node input delay(B)

Prop_Seg >= Delay A_to_B + Delay B_to_A

Prop_Seg >= 2 • [max(node output delay+bus line delay + node input delay)]

In this example, both nodes A and B are transmitters performing an arbitration for the CAN bus. The node A has sent its start of frame bit less than one bit time earlier than node B, therefore node B has

Copyright © 2011, Texas Instruments Incorporated

synchronized itself to the received edge from recessive to dominant. Since node B has received this edge delay(A_to_B) after it has been transmitted, node B's bit timing segments are shifted with regard to node A. Node B sends an identifier with higher priority and so it will win the arbitration at a specific identifier bit when it transmits a dominant bit while node A transmits a recessive bit. The dominant bit transmitted by node B will arrive at node A after the delay (B_to_A).

Due to oscillator tolerances, the actual position of node A's sample point can be anywhere inside the nominal range of node A's Phase Buffer Segments, so the bit transmitted by node B must arrive at node A before the start of Phase_Seg1. This condition defines the length of Prop_Seg.

If the edge from recessive to dominant transmitted by node B would arrive at node A after the start of Phase_Seg1, it could happen that node A samples a recessive bit instead of a dominant bit, resulting in a bit error and the destruction of the current frame by an error flag.

This error only occurs when two nodes arbitrate for the CAN bus which have oscillators of opposite ends of the tolerance range and are separated by a long bus line; this is an example of a minor error in the bit timing configuration (Prop_Seg too short) that causes sporadic bus errors.

Some CAN implementations provide an optional 3 Sample Mode. The DCAN does not. In this mode, the CAN bus input signal passes a digital low-pass filter, using three samples and a majority logic to determine the valid bit value. This results in an additional input delay of 1 t_q, requiring a longer Prop_Seg.

23.3.9.1.3 Phase Buffer Segments and Synchronization

The phase buffer segments (Phase_Seg1 and Phase_Seg2) and the synchronization jump width (SJW) are used to compensate for the oscillator tolerance.

The phase buffer segments surround the sample point and may be lengthened or shortened by synchronization.

The synchronization jump width (SJW) defines how far the resynchronizing mechanism may move the sample point inside the limits defined by the phase buffer segments to compensate for edge phase errors.

Synchronizations occur on edges from recessive to dominant. Their purpose is to control the distance between edges and sample points.

Edges are detected by sampling the actual bus level in each time quantum and comparing it with the bus level at the previous sample point. A synchronization may be done only if a recessive bit was sampled at the previous sample point and if the actual time quantum's bus level is dominant.

An edge is synchronous if it occurs inside of Sync_Seg; otherwise, its distance to the Sync_Seg is the edge phase error, measured in time quanta. If the edge occurs before Sync_Seg, the phase error is negative, else it is positive.

Two types of synchronization exist: hard synchronization and resynchronizing. A hard synchronization is done once at the start of a frame; inside a frame, only resynchronization is possible.

- Hard Synchronization

  After a hard synchronization, the bit time is restarted with the end of Sync_Seg, regardless of the edge phase error. Thus hard synchronization forces the edge which has caused the hard synchronization, to lie within the synchronization segment of the restarted bit time.

- Bit Resynchronizations

  Resynchronization leads to a shortening or lengthening of the Bit time such that the position of the sample point is shifted with regard to the edge.

  When the phase error of the edge which causes resynchronization is positive, Phase_Seg1 is lengthened. If the magnitude of the phase error is less than SJW, Phase_Seg1 is lengthened by the magnitude of the phase error, else it is lengthened by SJW.

  When the phase error of the edge which causes Resynchronization is negative, Phase_Seg2 is shortened. If the magnitude of the phase error is less than SJW, Phase_Seg2 is shortened by the magnitude of the phase error, else it is shortened by SJW.

Copyright © 2011, Texas Instruments Incorporated

If the magnitude of the phase error of the edge is less than or equal to the programmed value of SJW, the results of hard synchronization and resynchronization are the same. If the magnitude of the phase error is larger than SJW, the resynchronization cannot compensate the phase error completely, and an error of (phase error - SJW) remains.

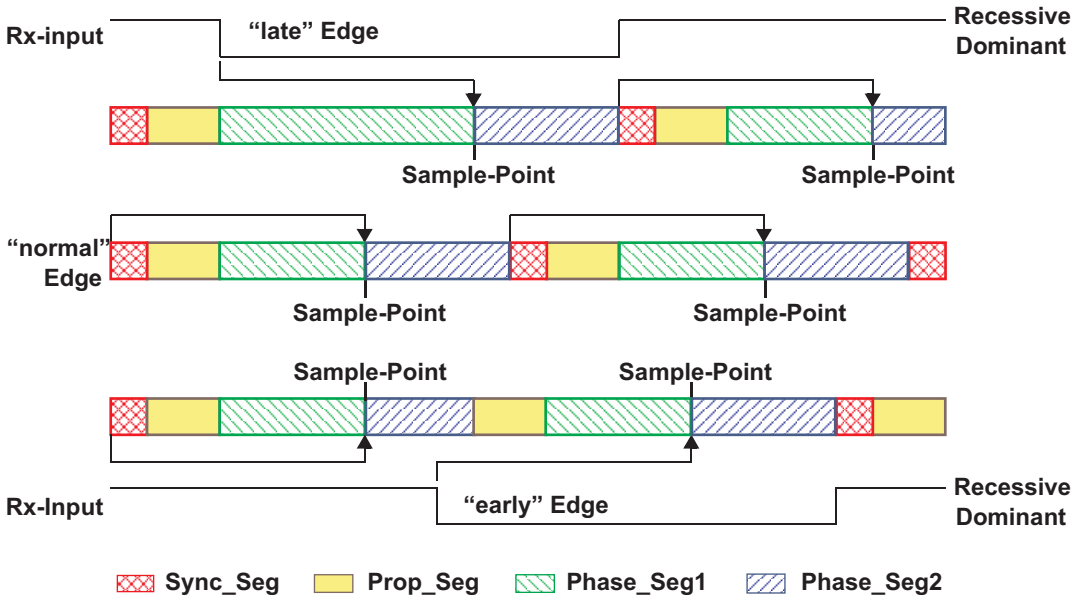
Only one synchronization may be done between two sample points. The synchronizations maintain a minimum distance between edges and sample points, giving the bus level time to stabilize and filtering out spikes that are shorter than (Prop_Seg + Phase_Seg1).

Apart from noise spikes, most synchronizations are caused by arbitration. All nodes synchronize “hard” on the edge transmitted by the “leading” transceiver that started transmitting first, but due to propagation delay times, they cannot become ideally synchronized. The leading transmitter does not necessarily win the arbitration; therefore, the receivers have to synchronize themselves to different transmitters that subsequently take the lead and that are differently synchronized to the previously leading transmitter. The same happens at the acknowledge field, where the transmitter and some of the receivers will have to synchronize to that receiver that takes the lead in the transmission of the dominant acknowledge bit.

Synchronizations after the end of the arbitration will be caused by oscillator tolerance, when the differences in the oscillator’s clock periods of transmitter and receivers sum up during the time between synchronizations (at most ten bits). These summarized differences may not be longer than the SJW, limiting the oscillator’s tolerance range.

Figure 23-15 shows how the phase buffer segments are used to compensate for phase errors. There are three drawings of each two consecutive bit timings. The upper drawing shows the synchronization on a “late” edge, the lower drawing shows the synchronization on an “early” edge, and the middle drawing is the reference without synchronization.

Figure 23-15. Synchronization on Late and Early Edges



In the first example, an edge from recessive to dominant occurs at the end of Prop_Seg. The edge is "late" since it occurs after the Sync_Seg. Reacting to the late edge, Phase_Seg1 is lengthened so that the distance from the edge to the sample point is the same as it would have been from the Sync_Seg to the sample point if no edge had occurred. The phase error of this late edge is less than SJW, so it is fully compensated and the edge from dominant to recessive at the end of the bit, which is one nominal bit time long, occurs in the Sync_Seg.

In the second example, an edge from recessive to dominant occurs during Phase_Seg2. The edge is "early" since it occurs before a Sync_Seg. Reacting to the early edge, Phase_Seg2 is shortened and Sync_Seg is omitted, so that the distance from the edge to the sample point is the same as it would have been from a Sync_Seg to the sample point if no edge had occurred. As in the previous example, the magnitude of this early edge’s phase error is less than SJW, so it is fully compensated.

Copyright © 2011, Texas Instruments Incorporated

The phase buffer segments are lengthened or shortened temporarily only; at the next bit time, the segments return to their nominal programmed values.

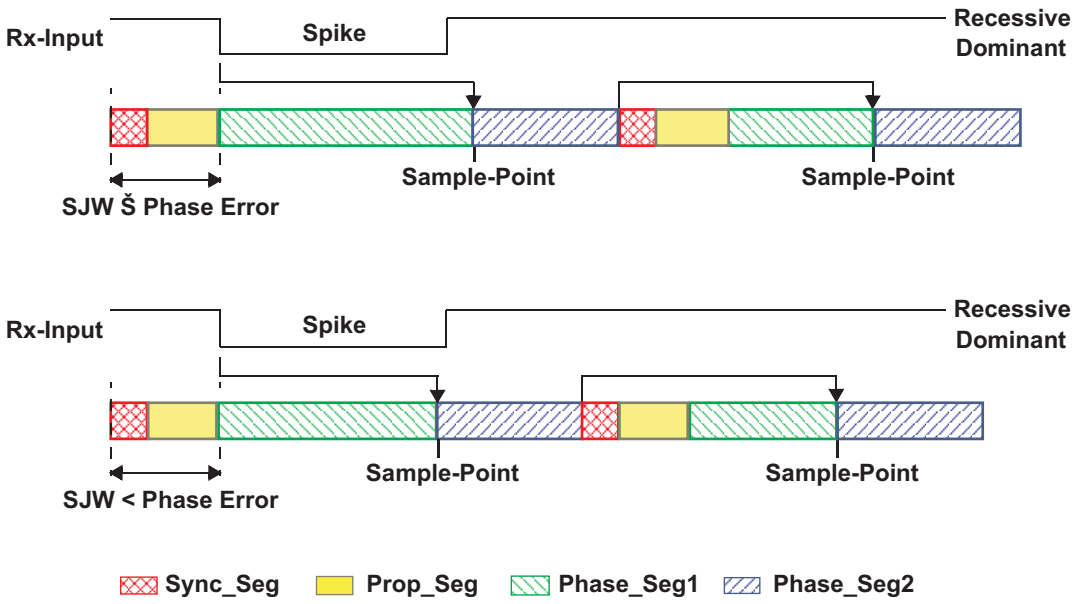
In these examples, the bit timing is seen from the point of view of the CAN implementation's state machine, where the bit time starts and ends at the sample points. The state machine omits Sync_Seg when synchronizing on an early edge because it cannot subsequently redefine that time quantum of Phase_Seg2 where the edge occurs to be the Sync_Seg.

Figure 23-16 shows how short dominant noise spikes are filtered by synchronizations. In both examples, the spike starts at the end of Prop_Seg and has the length of (Prop_Seg + Phase_Seg1).

In the first example, the synchronization jump width is greater than or equal to the phase error of the spike's edge from recessive to dominant. Therefore the sample point is shifted after the end of the spike; a recessive bus level is sampled.

In the second example, SJW is shorter than the phase error, so the sample point cannot be shifted far enough; the dominant spike is sampled as actual bus level.

Figure 23-16. Filtering of Short Dominant Spikes



23.3.9.1.4 Oscillator Tolerance Range

With the introduction of CAN protocol version 1.2, the option to synchronize on edges from dominant to recessive became obsolete. Only edges from recessive to dominant are considered for synchronization. The protocol update to version 2.0 (A and B) had no influence on the oscillator tolerance.

The tolerance range df for an oscillator's frequency f_{osc} around the nominal frequency f_{nom} with:

$$(1 - df) \bullet f_{nom} \le f_{osc} \le (1 + df) \bullet f_{nom}$$

depends on the proportions of Phase_Seg1, Phase_Seg2, SJW, and the bit time. The maximum tolerance df is the defined by two conditions (both shall be met):

$$\text{I:} \quad df \le \frac{\min(TSeg1, TSeg2)}{2x\left(13x\left(bit_time - TSeg2\right)\right)}$$

$$\text{II:} \quad df \le \frac{SJW}{20xbit_time}$$

It has to be considered that SJW may not be larger than the smaller of the phase buffer segments and that the propagation time segment limits that part of the bit time that may be used for the phase buffer segments.

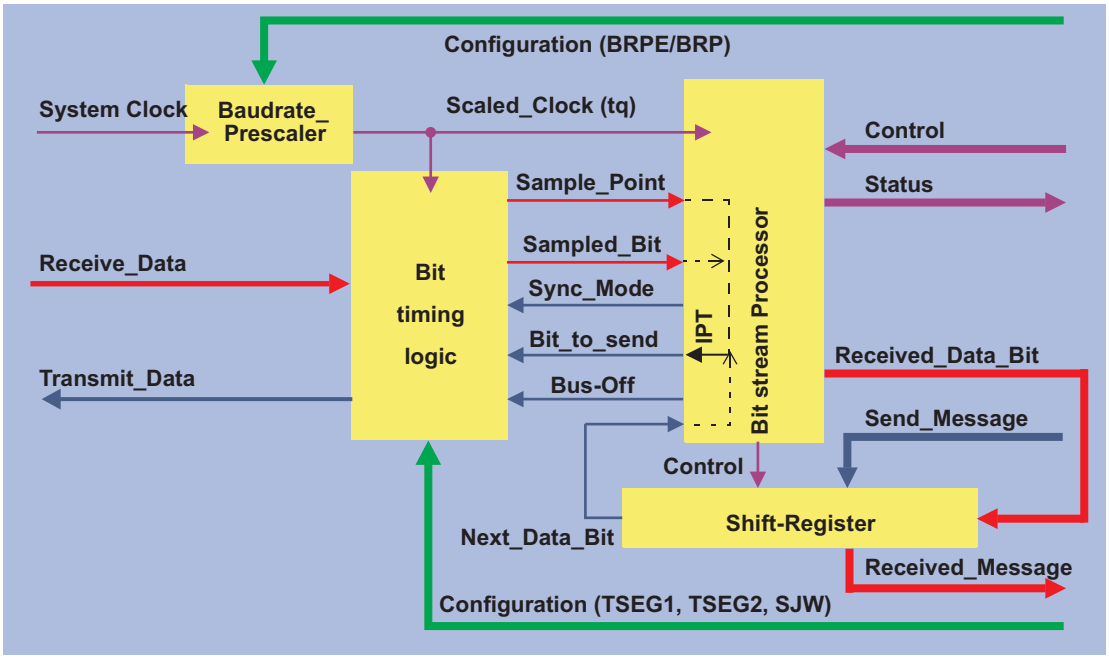
Copyright © 2011, Texas Instruments Incorporated

The combination Prop_Seg = 1 and Phase_Seg1 = Phase_Seg2 = SJW = 4 allows the largest possible oscillator tolerance of 1.58%. This combination with a propagation time segment of only 10% of the bit time is not suitable for short bit times; it can be used for bit rates of up to 125 kBit/s (bit time = 8 µs) with a bus length of 40 m.

23.3.9.2 DCAN Bit Timing Registers

In the DCAN, the bit timing configuration is programmed in two register bytes, additionally a third byte for a baud rate prescaler extension of four bits (BREP) is provided. The sum of Prop_Seg and Phase_Seg1 (as TSEG1) is combined with Phase_Seg2 (as TSEG2) in one byte, SJW and BRP (plus BRPE in third byte) are combined in the other byte (see Figure 23-17).

Figure 23-17. Structure of the CAN Core's CAN Protocol Controller



In this bit timing register, the components TSEG1, TSEG2, SJW and BRP have to be programmed to a numerical value that is one less than its functional value; so instead of values in the range of [1…n], values in the range of [0…–1] are programmed. That way, e.g., SJW (functional range of [1…4]) is represented by only two bits.

Therefore, the length of the bit time is (programmed values) [TSEG1 + TSEG2 + 3] t_q or (functional values) [Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] t_q.

The data in the bit timing register (BTR) is the configuration input of the CAN protocol controller. The baud rate prescaler (configured by BRPE/BRP) defines the length of the time quantum (the basic time unit of the bit time); the bit timing logic (configured by TSEG1, TSEG2, and SJW) defines the number of time quanta in the bit time.

The processing of the bit time, the calculation of the position of the sample point, and occasional synchronizations are controlled by the bit timing state machine, which is evaluated once each time quantum. The rest of the CAN protocol controller, the bit stream processor (BSP) state machine, is evaluated once each bit time, at the sample point.

The shift register serializes the messages to be sent and parallelizes received messages. Its loading and shifting is controlled by the BSP. The BSP translates messages into frames and vice versa. It generates and discards the enclosing fixed format bits, inserts and extracts stuff bits, calculates and checks the CRC code, performs the error management, and decides which type of synchronization is to be used. It is evaluated at the sample point and processes the sampled bus input bit. The time after the sample point that is needed to calculate the next bit to be sent (e.g., data bit, CRC bit, stuff bit, error flag, or idle) is called the information processing time (IPT), which is 0 tq for the DCAN.

Copyright © 2011, Texas Instruments Incorporated

Generally, the IPT is CAN controller-specific, but may not be longer than 2 tq. The IPC length is the lower limit of the programmed length of Phase_Seg2. In case of a synchronization, Phase_Seg2 may be shortened to a value less than IPT, which does not affect bus timing.

23.3.9.2.1 Calculation of the Bit Timing Parameters

Usually, the calculation of the bit timing configuration starts with a desired bit rate or bit time. The resulting bit time (1 / Bit rate) must be an integer multiple of the CAN clock period.

NOTE: 8 MHz is the minimum CAN clock frequency required to operate the DCAN at a bit rate of 1 MBit/s.

The bit time may consist of 8 to 25 time quanta. The length of the time quantum t_q is defined by the baud rate prescaler with t_q = (Baud Rate Prescaler) / CAN_CLK. Several combinations may lead to the desired bit time, allowing iterations of the following steps.

First part of the bit time to be defined is the Prop_Seg. Its length depends on the delay times measured in the system. A maximum bus length as well as a maximum node delay has to be defined for expandible CAN bus systems. The resulting time for Prop_Seg is converted into time quanta (rounded up to the nearest integer multiple of t_q).

The Sync_Seg is 1 t_q long (fixed), leaving (bit time – Prop_Seg – 1) t_q for the two Phase Buffer Segments. If the number of remaining t_q is even, the Phase Buffer Segments have the same length, Phase_Seg2 = Phase_Seg1, else Phase_Seg2 = Phase_Seg1 + 1.

The minimum nominal length of Phase_Seg2 has to be regarded as well. Phase_Seg2 may not be shorter than any CAN controller's Information Processing Time in the network, which is device dependent and can be in the range of [0…2] t_q.

The length of the synchronization jump width is set to its maximum value, which is the minimum of four (4) and Phase_Seg1.

The oscillator tolerance range necessary for the resulting configuration is calculated by the formulas given in Section 23.3.9.2.3.

If more than one configurations are possible to reach a certain Bit rate, it is recommended to choose the configuration which allows the highest oscillator tolerance range.

CAN nodes with different clocks require different configurations to come to the same bit rate. The calculation of the propagation time in the CAN network, based on the nodes with the longest delay times, is done once for the whole network.

The CAN system's oscillator tolerance range is limited by the node with the lowest tolerance range.

The calculation may show that bus length or bit rate have to be decreased or that the oscillator frequencies' stability has to be increased in order to find a protocol compliant configuration of the CAN bit timing.

The resulting configuration is written into the bit timing register:

Tseg2 = Phase_Seg2-1

Tseg1 = Phase_Seg1+ Prop_Seg-1

SJW = SynchronizationJumpWidth-1

BRP = Prescaler-1

23.3.9.2.2 Example for Bit Timing at High Baud Rate

In this example, the frequency of CAN_CLK is 10 MHz, BRP is 0, the bit rate is 1 MBit/s.

Copyright © 2011, Texas Instruments Incorporated

t_q	100 ns	=	t_{CAN_CLK}
delay of bus driver	60 ns	=	
delay of receiver circuit	40 ns	=	
delay of bus line (40 m)	220 ns	=	
t_{Prop}	700 ns	=	INT (2*delays + 1) = 7 • t_q
t_{SJW}	100 ns	=	1 • t_q
t_{TSeg1}	800 ns	=	t_{Prop} + t_{SJW}
t_{TSeg2}	100 ns	=	Information Processing Time + 1 • t_q
$t_{Sync-Seg}$	100 ns	=	1 • t_q
bit time	1000 ns	=	$t_{Sync-Seg}$ + t_{TSeg1} + t_{TSeg2}
tolerance for CAN_CLK	0.43 %	=	$\frac{(\min(TSeg1, TSeg2))}{2x(13x(bit_time - TSeg2))}$
		=	$\frac{0.1\,\mu s}{2x(13x(1\,\mu s - 0.1\,\mu s))}$

In this example, the concatenated bit time parameters are $(1\text{-}1)_3$&$(8\text{-}1)_4$&$(1\text{-}1)_2$&$(1\text{-}1)_6$, so the bit timing register is programmed to = 00000700.

23.3.9.2.3 Example for Bit Timing at Low Baud Rate

In this example, the frequency of CAN_CLK is 2 MHz, BRP is 1, the bit rate is 100 KBit/s.

t_q	1 µs	=	t_{CAN_CLK}
Delay of bus driver	200 ns	=	
Delay of receiver circuit	80 ns	=	
Delay of bus line (40 m)	220 ns	=	
t_{Prop}	1 µs	=	1 • t_q
t_{SJW}	4 µs	=	4 • t_q
t_{TSeg1}	5 µs	=	t_{Prop} + t_{SJW}
t_{TSeg2}	3 µs	=	Information Processing Time + 3 • t_q
$t_{Sync-Seg}$	1 µs	=	1 • t_q
Bit time	9 µs	=	$t_{Sync-Seg}$ + t_{TSeg1} + t_{TSeg2}
Tolerance for CAN_CLK		=	$\frac{(\min(TSeg1, TSeg2))}{2x(13x(bit_time - TSeg2))}$
		=	$\frac{0.1\,\mu s}{2x(13x(1\,\mu s - 0.1\,\mu s))}$

In this example, the concatenated bit time parameters are $(3\text{-}1)_3$&$(5\text{-}1)_4$&$(4\text{-}1)_2$&$(2\text{-}1)_6$, so the bit timing register is programmed to = 0x000024C1.

23.3.10 Message Interface Register Sets

The interface register sets control the CPU read and write accesses to the message RAM. There are two interface registers sets for read/write access, IF1 and IF2 and one interface register set for read access only, IF3.

Due to the structure of the message RAM, it is not possible to change single bits or bytes of a message object. Instead, always a complete message object in the message RAM is accessed. Therefore the data transfer from the IF1/IF2 registers to the message RAM requires the message handler to perform a read-modify-write cycle: First those parts of the message object that are not to be changed are read from the message RAM into the interface register set, and after the update the whole content of the interface register set is written into the message object.

After the partial write of a message object, those parts of the interface register set that are not selected in the command register, will be set to the actual contents of the selected message object.

After the partial read of a message object, those parts of the interface register set that are not selected in the command register, will be left unchanged.

By buffering the data to be transferred, the interface register sets avoid conflicts between concurrent CPU accesses to the message RAM and CAN message reception and transmission. A complete message object (see Section 23.3.11.1) or parts of the message object may be transferred between the message RAM and the IF1/IF2 register set (see Section 23.4.19) in one single transfer. This transfer, performed in parallel on all selected parts of the message object, guarantees the data consistency of the CAN message.

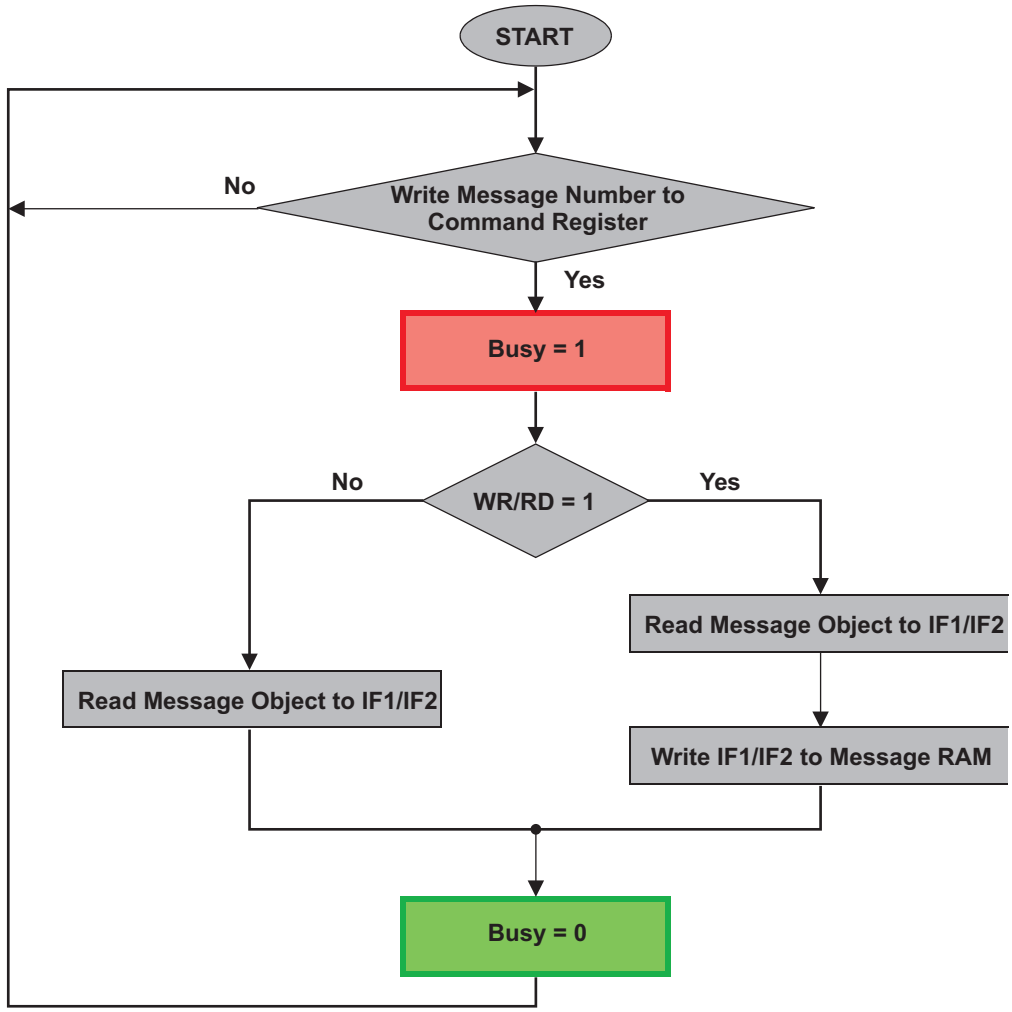
23.3.10.1 Message Interface Register Sets 1 and 2

The IF1 and IF2 register sets control the data transfer to and from the message object. The command register addresses the desired message object in the message RAM and specifies whether a complete message object or only parts should be transferred. The data transfer is initiated by writing the message number to the bits [7:0] of the command register.

When the CPU initiates a data transfer between the IF1/IF2 registers and message RAM, the message handler sets the busy bit in the respective command register to ‘1’. After the transfer has completed, the busy bit is set back to ‘0’ (see Figure 23-18).

Copyright © 2011, Texas Instruments Incorporated

Figure 23-18. Data Transfer Between IF1/IF2 Registers and Message RAM



23.3.10.2 IF3 Register Set

The IF3 register set can automatically be updated with received message objects without the need to initiate the transfer from message RAM by CPU. The intention of this feature of IF3 is to provide an interface for the DMA to read packets efficiently. The automatic update functionality can be programmed for each message object (Section 23.4.28).

All valid message objects in message RAM which are configured for automatic update, will be checked for active NewDat flags. If such a message object is found, it will be transferred to the IF3 register (if no previous DMA transfers are ongoing), controlled by IF3 Observation register. If more than one NewDat flag is active, the message object with the lowest number has the highest priority for automatic IF3 update.

The NewDat bit in the message object will be reset by a transfer to IF3.

If DCAN internal IF3 update is complete, a DMA request is generated. The DMA request stays active until first read access to one of the IF3 registers. The DMA functionality has to be enabled by setting bit DE3 in CAN control register. Please refer to the device datasheet to find out if this DMA source is available.

NOTE: The IF3 register set can not be used for transferring data into message objects.

Copyright © 2011, Texas Instruments Incorporated

23.3.11 Message RAM

The DCAN message RAM contains message objects and parity bits for the message objects. There are up to 64 message objects in the message RAM.

During normal operation, accesses to the message RAM are performed via the interface register sets, and the CPU cannot directly access the message RAM.

The interface register sets IF1 and IF2 provide indirect read/write access from the CPU to the message RAM. The IF1 and IF2 register sets can buffer control and user data to be transferred to and from the message objects.

The third interface register set IF3 can be configured to automatically receive control and user data from the message RAM when a message object has been updated after reception of a CAN message. The CPU does not need to initiate the transfer from message RAM to IF3 register set.

The message handler avoids potential conflicts between concurrent accesses to message RAM and CAN frame reception/transmission.

There are two modes where the message RAM can be directly accessed by the CPU:

- Debug/Suspend mode (see Section 23.3.11.3)
- RAM Direct Access (RDA) mode (see Section 23.3.11.4)

Copyright © 2011, Texas Instruments Incorporated

23.3.11.1 Structure of Message Objects

Table 23-8 shows the structure of a message object.

The grayed fields are those parts of the message object which are represented in dedicated registers. For example, the transmit request flags of all message objects are represented in centralized transmit request registers.

Table 23-8. Structure of a Message Object

Message Object												
UMask	**Msk[28:0]**	**MXtd**	**MDir**	**EoB**	**unused**	**NewDat**	**MsgLst**	**RxIE**	**TxIE**	**IntPnd**	**RmtEn**	**TxRqst**
MsgVal	ID[28:0]	Xtd	Dir	DLC[3:0]	Data 0	Data 1	Data 2	Data 3	Data 4	Data 5	Data 6	Data 7

Table 23-9. Field Descriptions

Name	Value	Description
MsgVal		Message valid
	0	The message object is ignored by the message handler.
	1	The message object is to be used by the message handler.
		Note: This bit may be kept at level '1' even when the identifier bits ID[28:0], the control bits Xtd, Dir, or the data length code are changed. It should be reset if the Messages Object is no longer required.
UMask		Use acceptance mask
	0	Mask bits (Msk[28:0], MXtd and MDir) are ignored and not used for acceptance filtering.
	1	Mask bits are used for acceptance filtering.
		Note: If the UMask bit is set to one, the message object's mask bits have to be programmed during initialization of the message object before MsgVal is set to one.
ID[28:0]		Message identifier
	ID[28:0]	29-bit ("extended") identifier bits
	ID[28:18]	11-bit ("standard") identifier bits
Msk[28:0]		Identifier mask
	0	The corresponding bit in the message identifier is not used for acceptance filtering (don't care).
	1	The corresponding bit in the message identifier is used for acceptance filtering.
Xtd		Mask extended identifier
	0	The extended identifier bit (IDE) has no effect on the acceptance filtering.
	1	The extended identifier bit (IDE) is used for acceptance filtering.
		Note: When 11-bit ("standard") Identifiers are used for a message object, the identifiers of received data frames are written into bits ID[28:18]. For acceptance filtering, only these bits together with mask bits Msk[28:18] are considered.
Dir		Message direction
	0	Direction = receive: On TxRqst, a remote frame with the identifier of this message object is transmitted. On reception of a data frame with matching identifier, the message is stored in this message object.
	1	Direction = transmit: On TxRqst, a data frame is transmitted. On reception of a remote frame with matching identifier, the TxRqst bit of this message object is set (if RmtEn = one).
MDir		Mask message direction
	0	The message direction bit (Dir) has no effect on the acceptance filtering.
	1	The message direction bit (Dir) is used for acceptance filtering.
EOB		End of block
	0	The message object is part of a FIFO Buffer block and is not the last message object of this FIFO Buffer block.
	1	The message object is a single message object or the last message object in a FIFO Buffer Block.
		Note: This bit is used to concatenate multiple message objects to build a FIFO Buffer. For single message objects (not belonging to a FIFO Buffer), this bit must always be set to one.

Copyright © 2011, Texas Instruments Incorporated

Table 23-9. Field Descriptions (continued)

Name	Value	Description
NewDat		New data
	0	No new data has been written into the data bytes of this message object by the message handler since the last time when this flag was cleared by the CPU.
	1	The message handler or the CPU has written new data into the data bytes of this message object.
MsgLst		Message lost (only valid for message objects with direction = receive)
	0	No message was lost since the last time when this bit was reset by the CPU.
	1	The message handler stored a new message into this message object when NewDat was still set, so the previous message has been overwritten.
RxIE		Receive interrupt enable
	0	IntPnd will not be triggered after the successful reception of a frame.
	1	IntPnd will be triggered after the successful reception of a frame.
TxIE		Transmit interrupt enable
	0	IntPnd will not be triggered after the successful transmission of a frame.
	1	IntPnd will be triggered after the successful transmission of a frame.
IntPnd		Interrupt pending
	0	This message object is not the source of an interrupt.
	1	This message object is the source of an interrupt. The interrupt Identifier in the interrupt register will point to this message object if there is no other interrupt source with higher priority.
RmtEn		Remote enable
	0	At the reception of a remote frame, TxRqst is not changed.
	1	At the reception of a remote frame, TxRqst is set.
TxRqst		Transmit request
	0	This message object is not waiting for a transmission.
	1	The transmission of this message object is requested and is not yet done.
DLC[3:0]		Data length code
	0	Data frame has 0-8 data bits.
	1	Data frame has 8 data bytes.
		Note: The data length code of a message object must be defined to the same value as in the corresponding objects with the same identifier at other nodes. When the message handler stores a data frame, it will write the DLC to the value given by the received message.
Data 0		1st data byte of a CAN data frame
Data 1		2nd data byte of a CAN data frame
Data 2		3rd data byte of a CAN data frame
Data 3		4th data byte of a CAN data frame
Data 4		5th data byte of a CAN data frame
Data 5		6th data byte of a CAN data frame
Data 6		7th data byte of a CAN data frame
Data 7		8th data byte of a CAN data frame
		Note: Byte Data 0 is the first data byte shifted into the shift register of the CAN core during a reception, byte Data 7 is the last. When the message handler stores a data frame, it will write all the eight data bytes into a message object. If the data length code is less than 8, the remaining bytes of the message object may be overwritten by undefined values.

23.3.11.2 Addressing Message Objects in RAM

The starting location of a particular message object in RAM is:
Message RAM base address + (message object number) * 0x20

This means that message object 1 starts at offset 0x0020; message object 2 starts at offset 0x0040, etc.

‘0’ is not a valid message object number.

The base address for DCAN0 RAM is 0x481C_D000 and DCAN1 RAM is 0x481D_1000.

Message object number 1 has the highest priority.

Table 23-10. Message RAM addressing in Debug/Suspend and RDA Mode

Message Object Number	Offset From Base Address	Word Number	Debug/Suspend Mode, see Section 23.3.11.3	RDA mode, see Section 23.3.11.4

23.3.11.3 Message RAM Representation in Debug/Suspend Mode

In debug/suspend mode, the message RAM will be memory mapped. This allows the external debug unit to access the message RAM.

NOTE: During debug/suspend mode, the message RAM cannot be accessed via the IFx register sets.

Table 23-11. Message RAM Representation in Debug/Suspend Mode

Bit #	31/15	30/14	29/13	29/12	27/11	26/10	25/9	24/8	23/7	22/6	21/5	20/4	19/3	18/2	17/1	16/0

	ID[15:0]															
MsgAddr + 0x0C	Reserved															
	Rsvd	MsgLst	Rsvd	UMask	TxIE	RxTE	RmtEn	Rsvd	EOB	Reserved			DLC[3:0]			
MsgAddr + 0x10	Data 3								Data 2							
	Data 1								Data 0							
MsgAddr + 0x14	Data 7								Data 6							
	Data 5								Data 4							

23.3.11.4 Message RAM Representation in Direct Access Mode

When the RDA bit in the test register is set while the DCAN module is in test mode (test bit in the CAN control register is set), the CPU has direct access to the message RAM. Due to the 32-bit bus structure, the RAM is split into word lines to support this feature. The CPU has access to one word line at a time only.

In RAM direct access mode, the RAM is represented by a continuous memory space within the address frame of the DCAN module, starting at the message RAM base address.

Note: During direct access mode, the message RAM cannot be accessed via the IFx register sets.

Any read or write to the RAM addresses for RamDirectAccess during normal operation mode (TestMode bit or RDA bit not set) will be ignored.

Table 23-12. Message RAM Representation in RAM Direct Access Mode

Bit #	31/15	30/14	29/13	29/12	27/11	26/10	25/9	24/8	23/7	22/6	21/5	20/4	19/3	18/2	17/1	16/0

	MsgLst				Unused				Msg Lst	UMask	TxIE	RxTE	Rmt En	EOB	MXtd	MDir

NOTE: Writes to unused bits have no effect.

23.3.12 GIO Support

The CAN_RX and CAN_TX pins of the DCAN module can be used as general purpose IO pins, if CAN functionality is not needed. This function is controlled by the CAN TX IO control register (DCAN TIOC) (see Section 23.4.29) and the CAN RX IO control register (DCAN RIOC) (see Section 23.4.30).

Copyright © 2011, Texas Instruments Incorporated

23.4 DCAN Control Registers

After hardware reset, the registers of the DCAN hold the values shown in the register descriptions.

Additionally, the Bus-Off state is reset and the CAN_TX pin is set to recessive (HIGH). The Init bit in the CAN control register is set to enable the software initialization. The DCAN will not influence the CAN bus until the CPU resets Init to '0'.

LEGEND: R/W = Read/Write; R = Read only; WP = Write protected by init bit; -*n* = value after reset

Table 23-14. CAN Control Register (DCAN CTL) Field Descriptions

Bit	Field	Value	Description
31-26	Reserved	0	These bits are always read as 0. Writes have no effect.
26	WUBA		Automatic wake up on bus activity when in local power-down mode
		0	No detection of a dominant CAN bus level while in local power-down mode.
		1	Detection of a dominant CAN bus level while in local power-down mode is enabled. On occurrence of a dominant CAN bus level, the wake up sequence is started (Additional information can be found in *Local Power-Down Mode*).
			Note: The CAN message, which initiates the bus activity, cannot be received. This means that the first message received in power down and automatic wake-up mode, will be lost.
24	PDR		Request for local low power-down mode
		0	No application request for local low power-down mode. If the application has cleared this bit while DCAN in local power-down mode, also the Init bit has to be cleared.
		1	Local power-down mode has been requested by application. The DCAN will acknowledge the local power-down mode by setting bit PDA in the error and status register. The local clocks will be turned off by DCAN internal logic (Additional information can be found in *Local Power-Down Mode*).
23-21	Reserved	0	These bits are always read as 0. Writes have no effect.
20	DE3		Enable DMA request line for IF3
		0	Disabled
		1	Enabled
			Note: A pending DMA request for IF3 remains active until first access to one of the IF3 registers.
19	DE2		Enable DMA request line for IF2
		0	Disabled
		1	Enabled
			Note: A pending DMA request for IF2 remains active until first access to one of the IF2 registers.
18	DE1		Enable DMA request line for IF1
		0	Disabled
		1	Enabled
			Note: A pending DMA request for IF1 remains active until first access to one of the IF1 registers.
17	IE1		Interrupt line 1 enable
		0	Disabled - Module interrupt DCAN1INT is always low.
		1	Enabled - interrupts will assert line DCAN1INT to one; line remains active until pending interrupts are processed.

Copyright © 2011, Texas Instruments Incorporated

Table 23-14. CAN Control Register (DCAN CTL) Field Descriptions (continued)

Bit	Field	Value	Description
16	InitDbg		Internal init state while debug access
		0	Not in debug mode, or debug mode requested but not entered.
		1	Debug mode requested and internally entered; the DCAN is ready for debug accesses.
15	SWR		SW reset enable
		0	Normal Operation
		1	Module is forced to reset state. This bit will automatically get cleared after execution of SW reset after one OCP clock cycle. Note: To execute software reset, the following procedure is necessary: 1. Set Init bit to shut down CAN communication. 2. Set SWR bit additionally to Init bit.
14	Reserved	0	This bit is always read as 0. Writes have no effect.
13-10	PMD		Parity on/off
		0x5	Parity function disabled
		Others	Parity function enabled
9	ABO		Auto-Bus-On enable
		0	The Auto-Bus-On feature is disabled
		1	The Auto-Bus-On feature is enabled
8	IDS		Interruption debug support enable
		0	When Debug/Suspend mode is requested, DCAN will wait for a started transmission or reception to be completed before entering Debug/Suspend mode
		1	When Debug/Suspend mode is requested, DCAN will interrupt any transmission or reception, and enter Debug/Suspend mode immediately.
7	Test		Test mode enable
		0	Normal Operation
		1	Test Mode
6	CCE		Configuration change enable
		0	The CPU has no write access to the configuration registers.
		1	The CPU has write access to the configuration registers (when Init bit is set).
5	DAR		Disable automatic retransmission
		0	Automatic retransmission of not successful messages enabled.
		1	Automatic retransmission disabled.
4	Reserved	0	This bit is always read as 0. Writes have no effect.
3	EIE		Error interrupt enable
		0	Disabled - PER, BOff and EWarn bits can not generate an interrupt.
		1	Enabled - PER, BOff and EWarn bits can generate an interrupt at DCAN0INT line and affect the interrupt register.
2	SIE		Status change interrupt enable
		0	Disabled - WakeUpPnd, RxOk, TxOk and LEC bits can not generate an interrupt.
		1	Enabled - WakeUpPnd, RxOk, TxOk and LEC can generate an interrupt at DCAN0INT line and affect the interrupt register.
1	IE0		Interrupt line 0 enable
		0	Disabled - Module interrupt DCAN0INT is always low.
		1	Enabled - interrupts will assert line DCAN0INT to one; line remains active until pending interrupts are processed.
0	Init		Initialization
		0	Normal operation
		1	Initialization mode is entered

Copyright © 2011, Texas Instruments Incorporated

NOTE: The Bus-Off recovery sequence (refer to CAN specification) cannot be shortened by setting or resetting Init bit. If the module goes Bus-Off, it will automatically set the Init bit and stop all bus activities.

When the Init bit is cleared by the application again, the module will then wait for 129 occurrences of Bus Idle (129 * 11 consecutive recessive bits) before resuming normal operation. At the end of the bus-off recovery sequence, the error counters will be reset.

After the Init bit is reset, each time when a sequence of 11 recessive bits is monitored, a Bit0 error code is written to the error and status register, enabling the CPU to check whether the CAN bus is stuck at dominant or continuously disturbed, and to monitor the proceeding of the bus-off recovery sequence.

23.4.2 Error and Status Register (DCAN ES) and DCAN Parity Error EOI Register (PARITYERR_EOI)

The error and status register (DCAN ES) is shown in Figure 23-20 and described in Table 23-15. The DCAN Parity Error EOI register is shown in Figure 23-21 and described in Table 23-16.

Figure 23-20. Error and Status Register (DCAN ES)

Table 23-15. Error and Status Register (DCAN ES) Field Descriptions

Bit	Field	Value	Description
31-11	Reserved	0	These bits are always read as 0. Writes have no effect.
10	PDA		Local power-down mode acknowledge
		0	DCAN is not in local power-down mode.
		1	Application request for setting DCAN to local power-down mode was successful. DCAN is in local power-down mode.
9	WakeUp Pnd		Wake up pending. This bit can be used by the CPU to identify the DCAN as the source to wake up the system.
		0	No Wake Up is requested by DCAN.
		1	DCAN has initiated a wake up of the system due to dominant CAN bus while module power down.
			This bit will be reset if error and status register is read.

Copyright © 2011, Texas Instruments Incorporated

Table 23-15. Error and Status Register (DCAN ES) Field Descriptions (continued)

Bit	Field	Value	Description
8	PER		Parity error detected
		0	No parity error has been detected since last read access.
		1	The parity check mechanism has detected a parity error in the Message RAM.
			This bit will be reset if error and status register is read.
7	BOff		Bus-Off state
		0	The CAN module is not bus-off state.
		1	The CAN module is in bus-off state.
6	EWarn		Warning state
		0	Both error counters are below the error warning limit of 96.
		1	At least one of the error counters has reached the error warning limit of 96.
5	EPass		Error passive state
		0	On CAN Bus error, the DCAN could send active error frames.
		1	The CAN core is in the error passive state as defined in the CAN Specification.
4	RxOk		Received a message successfully
		0	No message has been successfully received since the last time when this bit was read by the CPU. This bit is never reset by DCAN internal events.
		1	A message has been successfully received since the last time when this bit was reset by a read access of the CPU (independent of the result of acceptance filtering).
			This bit will be reset if error and status register is read.
3	TxOk		Transmitted a message successfully
		0	No message has been successfully transmitted since the last time when this bit was read by the CPU. This bit is never reset by DCAN internal events.
		1	A message has been successfully transmitted (error free and acknowledged by at least one other node) since the last time when this bit was reset by a read access of the CPU.
			This bit will be reset if error and status register is read.
2-0	LEC		Last error code. The LEC field indicates the type of the last error on the CAN bus. This field will be cleared to '0' when a message has been transferred (reception or transmission) without error.
		0	No error
		1	Stuff error: More than five equal bits in a row have been detected in a part of a received message where this is not allowed.
		2	Form error: A fixed format part of a received frame has the wrong format.
		3	Ack error: The message this CAN core transmitted was not acknowledged by another node.
		4	Bit1 error: During the transmission of a message (with the exception of the arbitration field), the device wanted to send a recessive level (bit of logical value '1'), but the monitored bus value was dominant.
		5	Bit0 error: During the transmission of a message (or acknowledge bit, or active error flag, or overload flag), the device wanted to send a dominant level (logical value '0'), but the monitored bus level was recessive. During Bus-Off recovery, this status is set each time a sequence of 11 recessive bits has been monitored. This enables the CPU to monitor the proceeding of the Bus-Off recovery sequence (indicating the bus is not stuck at dominant or continuously disturbed).
		6	CRC error: In a received message, the CRC check sum was incorrect. (CRC received for an incoming message does not match the calculated CRC for the received data).
		7	No CAN bus event was detected since the last time the CPU read the error and status register. Any read access to the error and status register re-initializes the LEC to value '7.'

Copyright © 2011, Texas Instruments Incorporated

Table 23-16. Parity Error End of Interrupt Register (PARITYERR_EOI) Field Descriptions

Bit	Field	Value	Description
31-9	Reserved	0	These bits are always read as 0. Writes have no effect.
8	PARITYERR_ EOI		End of interrupt indication for parity error
		0	Has no effect writing
		1	Indicated end of interrupt for parity error
7-0	Reserved		These bits are always read as 0. Writes have no effect.

Interrupts are generated by bits PER, BOff and EWarn (if EIE bit in CAN control register is set) and by bits WakeUpPnd, RxOk, TxOk, and LEC (if SIE bit in CAN control register is set).

A change of bit EPass will not generate an interrupt.

PARITYERR_EOI is used to signal an end of interrupt of the parity error interrupt (dcan_parity) to the IP. PARITYERR_EOI register is a *Write only* register.

A read from this offset address will result in a read from the DCAN ES register, where as a write will result in a write to the PARITYERR_EOI register.

NOTE: Reading the error and status register clears the WakeUpPnd, PER, RxOk and TxOk bits and set the LEC to value '7.' Additionally, the status interrupt value (0x8000) in the interrupt register will be replaced by the next lower priority interrupt value. The EOI for all other interrupts (DCANINT0 and DCANINT1) are automatically handled by hardware.

NOTE: For debug support, the auto clear functionality of error and status register (clear of status flags by read) is disabled when in debug/suspend mode.

23.4.3 Error Counter Register (DCAN ERRC)

The error counter register (DCAN ERRC) is shown in Figure 23-22 and described in Table 23-17.

Figure 23-22. Error Counter Register (DCAN ERRC)

31															16
Reserved

23.4.4 Bit Timing Register (DCAN BTR)

The bit timing register (DCAN BTR) is shown in Figure 23-23 and described in Table 23-18.

Figure 23-23. Bit Timing Register (DCAN BTR)

31																20	19														16
Reserved																	BRPE														
R-0																	R-0														

15	14	12	11	8	7	6	5	0
Reserved	TSeg2		TSeg1		SJW		BRP	
R-0	R/WP-0x2		R/WP-0x3		R/WP-0		R/WP-0x1	

LEGEND: R = Read only; WP = Write protected by CCE bit; *-n* = value after reset

Table 23-18. Bit Timing Register (DCAN BTR) Field Descriptions

Bit	Field	Value	Description
31-20	Reserved	0	These bits are always read as 0. Writes have no effect.
19-16	BRPE	0x00-0x0F	Baud rate prescaler extension. Valid programmed values are 0 to 15. By programming BRPE the baud rate prescaler can be extended to values up to 1024.
15	Reserved	0	These bits are always read as 0. Writes have no effect.
14-12	TSeg2	0x0-0x7	Time segment after the sample point Valid programmed values are 0 to 7. The actual TSeg2 value which is interpreted for the bit timing will be the programmed TSeg2 value + 1.
11-8	TSeg1	0x01-0x0F	Time segment before the sample point Valid programmed values are 1 to15. The actual TSeg1 value interpreted for the bit timing will be the programmed TSeg1 value + 1.
7-6	SJW	0x0-0x3	Synchronization Jump Width Valid programmed values are 0 to 3. The actual SJW value interpreted for the synchronization will be the programmed SJW value + 1.
5-0	BRP	0x00-0x3F	Baud rate prescaler Value by which the CAN_CLK frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quanta. Valid programmed values are 0 to 63. The actual BRP value interpreted for the bit timing will be the programmed BRP value + 1.

NOTE: This register is only writable if CCE and Init bits in the CAN control register are set.

NOTE: The CAN bit time may be programmed in the range of 8 to 25 time quanta.

NOTE: The CAN time quantum may be programmed in the range of 1 to1024 CAN_CLK periods.

With a CAN_CLK of 8 MHz and BRPE = 0x00, the reset value of 0x00002301 configures the DCAN for a bit rate of 500kBit/s.

Copyright © 2011, Texas Instruments Incorporated

23.4.5 Interrupt Register (DCAN INT)

The interrupt register (DCAN INT) is shown in Figure 23-24 and described in Table 23-19.

Figure 23-24. Interrupt Register (DCAN INT)

31	24	23	16
Reserved		Int1ID[7:0]	
R-0		R-0	

15	0
Int0ID[15:0]	
R-0	

LEGEND: R = Read only; -*n* = value after reset

Table 23-19. Interrupt Register (DCAN INT) Field Descriptions

Bit	Field	Value	Description
31-24	Reserved	0	These bits are always read as 0. Writes have no effect.
23-16	Int1ID[23:16]		Interrupt 1 Identifier (indicates the message object with the highest pending interrupt)
		0x00	No interrupt is pending
		0x01-0x80	Number of message object which caused the interrupt.
		0x81-0xFF	Unused
			If several interrupts are pending, the CAN interrupt register will point to the pending interrupt with the highest priority. The DCAN1INT interrupt line remains active until Int1ID reaches value 0 (the cause of the interrupt is reset) or until IE1 is cleared.
			A message interrupt is cleared by clearing the message object's IntPnd bit.
			Among the message interrupts, the message object's interrupt priority decreases with increasing message number.
15-0	Int0ID[15:0]		Interrupt Identifier (the number here indicates the source of the interrupt)
		0x0000	No interrupt is pending
		0x0001-0x0080	Number of message object which caused the interrupt.
		0x0081-0x7FFF	Unused
		0x8000	Error and status register value is not 0x07.
		0x8001-0xFFFF	Unused
			If several interrupts are pending, the CAN interrupt register will point to the pending interrupt with the highest priority. The DCAN0INT interrupt line remains active until Int0ID reaches value 0 (the cause of the interrupt is reset) or until IE0 is cleared.
			The Status interrupt has the highest priority. Among the message interrupts, the message object's interrupt priority decreases with increasing message number.

Copyright © 2011, Texas Instruments Incorporated

23.4.6 Test Register (DCAN TEST)

The test register (DCAN TEST) is shown in Figure 23-25 and described in Table 23-20.

Figure 23-25. Test Register (DCAN TEST)

31												16
Reserved												
R-0												
15		10	9	8	7	6	5	4	3	2	1	0
Reserved			RDA	EXL	Rx	Tx[1:0]		LBack	Silent	Reserved		
R-0			R/WP-0	R/WP-0	R-U	R/WP-0		R/WP-0	R/WP-0	R-0		

LEGEND: R = Read only; WP = Write protected by test bit; *-n* = value after reset; U = Undefined

Table 23-20. Test Register (DCAN TEST) Field Descriptions

Bit	Field	Value	Description
31-10	Reserved	0	These bits are always read as 0. Writes have no effect.
9	RDA		RAM direct access enable
		0	Normal pperation
		1	Direct access to the RAM is enabled while in test mode
8	EXL		External loopback mode
		0	Disabled
		1	Enabled
7	Rx		Receive pin. Monitors the actual value of the CAN_RX pin
		0	The CAN bus is dominant
		1	The CAN bus is recessive
6-5	Tx[1:0]		Control of CAN_TX pin
		00	Normal operation, CAN_TX is controlled by the CAN core.
		01	Sample point can be monitored at CAN_TX pin.
		10	CAN_TX pin drives a dominant value.
		11	CAN_TX pin drives a recessive value.
4	LBack		Loopback mode
		0	Disabled
		1	Enabled
3	Silent		Silent mode
		0	Disabled
		1	Enabled
2-0	Reserved	0	These bits are always read as 0. Writes have no effect.

For all test modes, the test bit in CAN control register needs to be set to one. If test bit is set, the RDA, EXL, Tx1, Tx0, LBack and Silent bits are writable. Bit Rx monitors the state of pin CAN_RX and therefore is only readable. All test register functions are disabled when test bit is cleared.

NOTE: The test register is only writable if test bit in CAN control register is set.

NOTE: Setting Tx[1:0] other than '00' will disturb message transfer.

NOTE: When the internal loop-back mode is active (bit LBack is set), bit EXL will be ignored.

Copyright © 2011, Texas Instruments Incorporated

23.4.7 Parity Error Code Register (DCAN PERR)

The parity error code register (DCAN PERR) is shown in Figure 23-26 and described in Table 23-21.

Figure 23-26. Parity Error Code Register (DCAN PERR)

31	16
Reserved	
R-0	

15	11	10	8	7	0
Reserved		Word Number		Message Number	
R-0		R-U		R-U	

LEGEND: R = Read only; -*n* = value after reset; U = Undefined

Table 23-21. Parity Error Code Register (DCAN PERR) Field Descriptions

Bit	Field	Value	Description
31-11	Reserved	0	These bits are always read as 0. Writes have no effect.
10-8	Word Number	0x01-0x05	Word number where parity error has been detected RDA word number (1 to 5) of the message object (according to the message RAM representation in RDA mode).
7-0	Message Number	0x01-0x80	Message object number where parity error has been detected

If a parity error is detected, the PER flag will be set in the error and status register. This bit is not reset by the parity check mechanism; it must be reset by reading the error and status register.

In addition to the PER flag, the parity error code register will indicate the memory area where the parity error has been detected (message number and word number).

If more than one word with a parity error was detected, the highest word number with a parity error will be displayed.

After a parity error has been detected, the register will hold the last error code until power is removed.

Copyright © 2011, Texas Instruments Incorporated

23.4.8 Auto-Bus-On Time Register (DCAN ABOTR)

The Auto-Bus-On time register (DCAN ABOTR) is shown in Figure 23-27 and described in Table 23-22.

Figure 23-27. Auto-Bus-On Time Register (DCAN ABOTR)

31	16	15	0
ABO Time[31:16]		ABO Time[15:0]	
R/W-0		R/W-0	

LEGEND: R = Read only; W = Write only; -*n* = value after reset

Table 23-22. Auto-Bus-On Time Register (DCAN ABOTR) Field Descriptions

Bit	Field	Value	Description
31-0	ABO Time		Number of OCP clock cycles before a Bus-Off recovery sequence is started by clearing the Init bit. This function has to be enabled by setting bit ABO in CAN control register. The Auto-Bus-On timer is realized by a 32-bit counter that starts to count down to zero when the module goes Bus-Off. The counter will be reloaded with the preload value of the ABO time register after this phase.

NOTE: On write access to the CAN control register while Auto-Bus-On timer is running, the Auto-Bus-On procedure will be aborted.

NOTE: During Debug/Suspend mode, running Auto-Bus-On timer will be paused.

Copyright © 2011, Texas Instruments Incorporated

23.4.9 Transmission Request X Register (DCAN TXRQ X)

The transmission request X register (DCAN TXRQ X) is shown in Figure 23-28.

Figure 23-28. Transmission Request X Register (DCAN TXRQ X)

Copyright © 2011, Texas Instruments Incorporated

23.4.10 Transmission Request Registers (DCAN TXRQ12 to DCAN TXRQ78)

These registers hold the TxRqst bits of the implemented message objects. By reading out these bits, the CPU can check for pending transmission requests. The TxRqst bit in a specific message object can be set/reset by the CPU via the IF1/IF2 message interface registers, or by the message handler after reception of a remote frame or after a successful transmission.

The transmission request registers are shown in Table 23-23 and described in Table 23-24.

Table 23-23. Transmission Request Registers (DCAN TXRQ12 to DCAN TXRQ78)

23.4.11 New Data X Register (DCAN NWDAT X)

With the new data X register, the CPU can detect if one or more bits in the different new data registers are set. Each register bit represents a group of eight message objects. If at least on of the NewDat bits of these message objects are set, the corresponding bit in the new data X register will be set.

The new data X register (DCAN NWDAT X) is shown in Figure 23-29.

Figure 23-29. Transmission Request X Register (DCAN TXRQ X)

23.4.12 New Data Registers (DCAN NWDAT12 to DCAN NWDAT78)

These registers hold the NewDat bits of the implemented message objects. By reading out these bits, the CPU can check for new data in the message objects. The NewDat bit of a specific message object can be set/reset by the CPU via the IF1/IF2 interface register sets, or by the message handler after reception of a data frame or after a successful transmission.

The new data registers (DCAN NWDAT12 to DCAN NWDAT78) are shown in Table 23-25 and described in Table 23-26.

Table 23-25. New Data Registers (DCAN NWDAT12 to DCAN NWDAT78)

23.4.13 Interrupt Pending X Register (DCAN INTPND X)

With the interrupt pending X register, the CPU can detect if one or more bits in the different interrupt pending registers are set. Each bit of this register represents a group of eight message objects. If at least one of the IntPnd bits of these message objects are set, the corresponding bit in the interrupt pending X register will be set.

The interrupt pending X register (DCAN INTPND X) is shown in Figure 23-30.

Figure 23-30. Interrupt Pending X Register (DCAN INTPND X)

23.4.14 Interrupt Pending Registers (DCAN INTPND12 to DCAN INTPND78)

These registers hold the IntPnd bits of the implemented message objects. By reading out these bits, the CPU can check for pending interrupts in the message objects. The IntPnd bit of a specific message object can be set/reset by the CPU via the IF1/IF2 interface register sets, or by the message handler after a reception or a successful transmission.

The interrupt pending registers (DCAN INTPND12 to DCAN INTPND78) are shown in Table 23-27 and described in Table 23-28.

Table 23-27. New Data Registers (DCAN NWDAT12 to DCAN NWDAT78)

23.4.15 Message Valid X Register (DCAN MSGVAL X)

With the message valid X register, the CPU can detect if one or more bits in the different message valid registers are set. Each bit of this register represents a group of eight message objects. If at least one of the MsgVal bits of these message objects are set, the corresponding bit in the message valid X register will be set.

The message valid X register (DCAN MSGVAL X) is shown in Figure 23-31.

23.4.16 Message Valid Registers (DCAN MSGVAL12 to DCAN MSGVAL78)

These registers hold the MsgVal bits of the implemented message objects. By reading out these bits, the CPU can check which message objects are valid. The MsgVal bit of a specific message object can be set/reset by the CPU via the IF1/IF2 interface register sets, or by the message handler after a reception or a successful transmission.

The message valid registers (DCAN MSGVAL12 to MSGVAL78) is shown in Table 23-29 and described in Table 23-30.

23.4.17 Interrupt Multiplexer Registers (DCAN INTMUX12 to DCAN INTMUX78)

The IntMux flag determine for each message object, which of the two interrupt lines (DCAN0INT or DCAN1INT) will be asserted when the IntPnd of this message object is set. Both interrupt lines can be globally enabled or disabled by setting or clearing IE0 and IE1 bits in CAN control register.

The IntPnd bit of a specific message object can be set or reset by the CPU via the IF1/IF2 interface register sets, or by message handler after reception or successful transmission of a frame. This will also affect the Int0ID resp Int1ID flags in the interrupt register.

The interrupt multiplexer registers are shown in Table 23-31 and described in Table 23-32.

Table 23-31. Interrupt Multiplexer Registers (DCAN INTMUX12 to DCAN INTMUX78)

Offset/Register	31/15	30/14	29/13	29/12	27/11	26/10	25/9	24/8	23/7	22/6	21/5	20/4	19/3	18/2	17/1	16/0

23.4.18 IF1/IF2 Command Registers (DCAN IF1CMD, DCAN IF2CMD)

The IF1/IF2 Command Register (DCAN IF1CMD, DCAN IF2CMD) configure and initiate the transfer between the IF1/IF2 register sets and the message RAM. It is configurable which portions of the message object should be transferred.

A transfer is started when the CPU writes the message number to bits [7:0] of the IF1/IF2 command register. With this write operation, the Busy bit is automatically set to '1' to indicate that a transfer is in progress.

After 4 to 14 OCP clock cycles, the transfer between the interface register and the message RAM will be completed and the Busy bit is cleared. The maximum number of cycles is needed when the message transfer concurs with a CAN message transmission, acceptance filtering, or message storage.

If the CPU writes to both IF1/IF2 command registers consecutively (request of a second transfer while first transfer is still in progress), the second transfer will start after the first one has been completed.

The IF1/IF2 command registers are shown in Figure 23-32 and Figure 23-33 and described in Table 23-33.

NOTE: While Busy bit is one, IF1/IF2 register sets are write protected.

NOTE: For debug support, the auto clear functionality of the IF1/IF2 command registers (clear of DMAactive flag by r/w) is disabled during Debug/Suspend mode.

NOTE: If an invalid Message Number is written to bits [7:0] of the IF1/IF2 command register, the message handler may access an implemented (valid) message object instead.

Table 23-33. IF1/IF2 Command Registers (DCAN IF1CMD, DCAN IF2CMD) Field Descriptions

Bit	Field	Value	Description
31-24	Reserved	0	These bits are always read as 0. Writes have no effect.
23	WR/RD		Write/Read
		0	Direction = Read: Transfer direction is from the message object addressed by Message Number (Bits [7:0]) to the IF1/IF2 register set.
		1	Direction = Write: Transfer direction is from the IF1/IF2 register set to the message object addressed by Message Number (Bits [7:0]).
22	Mask		Access mask bits
		0	Mask bits will not be changed
		1	Direction = Read: The mask bits (identifier mask + MDir + MXtd) will be transferred from the message object addressed by Message Number (Bits [7:0]) to the IF1/IF2 register set.
			Direction = Write: The mask bits (identifier mask + MDir + MXtd) will be transferred from the IF1/IF2 register set to the message object addressed by Message Number (Bits [7:0]).
21	Arb		Access arbitration bits
		0	Arbitration bits will not be changed
		1	Direction = Read: The Arbitration bits (Identifier + Dir + Xtd + MsgVal) will be transferred from the message object addressed by Message Number (Bits [7:0]) to the corresponding IF1/IF2 register set.
			Direction = Write: The Arbitration bits (Identifier + Dir + Xtd + MsgVal) will be transferred from the IF1/IF2 register set to the message object addressed by Message Number (Bits [7:0]).
20	Control		Access control bits
		0	Control bits will not be changed
		1	Direction = Read: The message control bits will be transferred from the message object addressed by message number (Bits [7:0]) to the IF1/IF2 registerset.
			Direction = Write: The message control bits will be transferred from the IF1/IF2 registerset to the message object addressed by message number (Bits [7:0]).
			If the TxRqst/NewDat bit in this register(Bit [18]) is set, the TxRqst/ NewDat bit in the IF1/IF2 message control register will be ignored.
19	ClrIntPnd		Clear interrupt pending bit
		0	IntPnd bit will not be changed
		1	Direction = Read: Clears IntPnd bit in the message object.
			Direction = Write: This bit is ignored. Copying of IntPnd flag from IF1/IF2 Registers to message RAM can only be controlled by the control flag (Bit [20]).
18	TxRqst/NewDat		Access transmission request bit
		0	Direction = Read: NewDat bit will not be changed. Direction = Write: TxRqst/NewDat bit will be handled according to the control bit.
		1	Direction = Read: Clears NewDat bit in the message object. Direction = Write: Sets TxRqst/NewDat in message object.
			Note: If a CAN transmission is requested by setting TxRqst/NewDat in this register, the TxRqst/NewDat bits in the message object will be set to one independent of the values in IF1/IF2 message control Register.
			Note: A read access to a message object can be combined with the reset of the control bits IntPnd and NewDat. The values of these bits transferred to the IF1/IF2 message control registeralways reflect the status before resetting them.
17	Data A		Access Data Bytes 0-3
		0	Data Bytes 0-3 will not be changed.
		1	Direction = Read: The data bytes 0-3 will be transferred from the message object addressed by the Message Number (Bits [7:0]) to the corresponding IF1/IF2 registerset.
			Direction = Write: The data bytes 0-3 will be transferred from the IF1/IF2 registerset to the message object addressed by the Message Number (Bits [7:0]).
			Note: The duration of the message transfer is independent of the number of bytes to be transferred.

Copyright © 2011, Texas Instruments Incorporated

Table 23-33. IF1/IF2 Command Registers (DCAN IF1CMD, DCAN IF2CMD) Field Descriptions (continued)

Bit	Field	Value	Description
16	Data B		Access Data Bytes 4-7
		0	Data Bytes 4-7 will not be changed.
		1	Direction = Read: The data bytes 4-7 will be transferred from the message object addressed by Message Number (Bits [7:0]) to the corresponding IF1/IF2 registerset.
			Direction = Write: The data bytes 4-7 will be transferred from the IF1/IF2 registerset to the message object addressed by message number (Bits [7:0]).
			Note: The duration of the message transfer is independent of the number of bytes to be transferred.
15	Busy		Busy flag
		0	No transfer between IF1/IF2 register set and message RAM is in progress.
		1	Transfer between IF1/IF2 register set and message RAM is in progress.
			This bit is set to one after the message number has been written to bits [7:0]. IF1/IF2 register set will be write protected. The bit is cleared after read/write action has been finished.
14	DMAactive		Activation of DMA feature for subsequent internal IF1/IF2 update
		0	DMA request line is independent of IF1/IF2 activities.
		1	DMA is requested after completed transfer between IF1/IF2 register set and message RAM.
			The DMA request remains active until the first read or write to one of the IF1/IF2 registers; an exception is a write to Message Number (Bits [7:0]) when DMAactive is one.
			Note: Due to the auto reset feature of the DMAactive bit, this bit has to be set for each subsequent DMA cycle separately.
13-8	Reserved	0	These bits are always read as 0. Writes have no effect.
7-0	Message Number		Number of message object in message RAM which is used for data transfer
		0x00	Invalid message number
		0x01-0x80	Valid message numbers
		0x81-0xFF	Invalid message numbers

Copyright © 2011, Texas Instruments Incorporated

23.4.19 IF1/IF2 Mask Registers (DCAN IF1MSK, DCAN IF2MSK)

The bits of the IF1/IF2 mask registers mirror the mask bits of a message object. The function of the relevant message objects bits is described in *Structure of Message Objects*.

The IF1/IF2 mask registers (DCAN IF1MSK, DCAN IF2MSK) are shown in Figure 23-34 and Figure 23-35 and described in Table 23-34.

NOTE: While Busy bit of IF1/IF2 command register is one, IF1/IF2 register set is write protected.

Bit	Field	Value	Description
31	MXtd		Mask Extended Identifier
		0	The extended identifier bit (IDE) has no effect on the acceptance filtering.
		1	The extended identifier bit (IDE) is used for acceptance filtering.
			When 11-bit (“standard”) identifiers are used for a message object, the identifiers of received data frames are written into bits ID[28:18]. For acceptance filtering, only these bits together with mask bits Msk[28:18] are considered.
30	MDir		Mask Message Direction
		0	The message direction bit (Dir) has no effect on the acceptance filtering.
		1	The message direction bit (Dir) is used for acceptance filtering.
29	Reserved	0	These bits are always read as 0. Writes have no effect.
28-0	Msk[28:0]		Identifier Mask
		0	The corresponding bit in the identifier of the message object is not used for acceptance filtering (don't care).
		1	The corresponding bit in the identifier of the message object is used for acceptance filtering.

23.4.20 IF1/IF2 Arbitration Registers (DCAN IF1ARB, DCAN IF2ARB)

The bits of the IF1/IF2 arbitration registers mirror the arbitration bits of a message object. The function of the relevant message objects bits is described in *Structure of Message Objects*.

The IF1/IF2 arbitration registers (DCAN IF1ARB, DCAN IF2ARB) are shown in Figure 23-36 and Figure 23-37 and described in Table 23-35.

NOTE: While Busy bit of IF1/IF2 command register is one, IF1/IF2 register set is write protected.

R/WP-0

LEGEND: R = Read only; WP = Write protected (protected by busy bit); -*n* = value after reset

Table 23-35. IF1/IF2 Arbitration Registers (DCAN IF1ARB, DCAN IF2ARB) Field Descriptions

Bit	Field	Value	Description
31	MsgVal		Message valid
		0	The message object is ignored by the message handler.
		1	The message object is to be used by the message handler.
			The CPU should reset the MsgVal bit of all unused Messages Objects during the initialization before it resets bit Init in the CAN control register. This bit must also be reset before the identifier ID[28:0], the control bits Xtd, Dir or DLC[3:0] are modified, or if the messages object is no longer required.
30	Xtd		Extended identifier
		0	The 11-bit (“standard”) Identifier is used for this message object.
		1	The 29-bit (“extended”) Identifier is used for this message object.
29	Dir		Message direction
		0	Direction = receive: On TxRqst, a remote frame with the identifier of this message object is transmitted. On reception of a data frame with matching identifier, this message is stored in this message object.
		1	Direction = transmit: On TxRqst, the respective message object is transmitted as a data frame. On reception of a remote frame with matching identifier, the TxRqst bit of this message object is set (if RmtEn = 1).

Copyright © 2011, Texas Instruments Incorporated

Table 23-35. IF1/IF2 Arbitration Registers (DCAN IF1ARB, DCAN IF2ARB) Field Descriptions (continued)

Bit	Field	Value	Description
28-0	Msk[28:0]		Message identifier
		ID[28:0]	29-bit identifier (extended frame)
		ID[28:18]	11-bit identifier (standard frame)

The Arbitration bits ID[28:0], Xtd, and Dir are used to define the identifier and type of outgoing messages and (together with the mask bits Msk[28:0], MXtd, and MDir) for acceptance filtering of incoming messages.

A received message is stored into the valid message object with matching identifier and Direction = receive (data frame) or Direction = transmit (remote frame).

Extended frames can be stored only in message objects with Xtd = one, standard frames in message objects with Xtd = zero.

If a received message (data frame or remote frame) matches more than one valid message objects, it is stored into the one with the lowest message number.

Copyright © 2011, Texas Instruments Incorporated

23.4.21 IF1/IF2 Message Control Registers (DCAN IF1MCTL, DCAN IF2MCTL)

The bits of the IF1/IF2 message control registers mirror the message control bits of a message object. The function of the relevant message objects bits is described in *Structure of Message Objects*.

The IF1/IF2 message control registers (DCAN IF1MCTL, DCAN IF2MCTL) are shown in Figure 23-38 and Figure 23-39 and described in Table 23-36.

NOTE: While Busy bit of IF1/IF2 command register is one, IF1/IF2 register set is write protected.

Table 23-36. IF1/IF2 Message Control Registers (DCAN IF1MCTL, DCAN IF2MCTL) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	These bits are always read as 0. Writes have no effect.
15	NewDat		New data
		0	No new data has been written into the data portion of this message object by the message handler since the last time when this flag was cleared by the CPU.
		1	The message handler or the CPU has written new data into the data portion of this message object.
14	MsgLst		Message lost (only valid for message objects with direction = receive)
		0	No message lost since the last time when this bit was reset by the CPU.
		1	The message handler stored a new message into this object when NewDat was still set, so the previous message has been overwritten.
13	IntPnd		Interrupt pending
		0	This message object is not the source of an interrupt.
		1	This message object is the source of an interrupt. The Interrupt Identifier in the interrupt register will point to this message object if there is no other interrupt source with higher priority.
12	UMask		Use acceptance mask
		0	Mask ignored
		1	Use mask (Msk[28:0], MXtd, and MDir) for acceptance filtering
			If the UMask bit is set to one, the message object's mask bits have to be programmed during initialization of the message object before MsgVal is set to one.

Table 23-36. IF1/IF2 Message Control Registers (DCAN IF1MCTL, DCAN IF2MCTL) Field Descriptions (continued)

Bit	Field	Value	Description
11	TxIE		Transmit interrupt enable
		0	IntPnd will not be triggered after the successful transmission of a frame.
		1	IntPnd will be triggered after the successful transmission of a frame.
10	RxIE		Receive interrupt enable
		0	IntPnd will not be triggered after the successful reception of a frame.
		1	IntPnd will be triggered after the successful reception of a frame.
9	RmtEn		Remote enable
		0	At the reception of a remote frame, TxRqst is not changed.
		1	At the reception of a remote frame, TxRqst is set.
8	TxRqst		Transmit request
		0	This message object is not waiting for a transmission.
		1	The transmission of this message object is requested and is not yet done.
7	EoB		Data frame has 0-8 data bits.
		0	Data frame has 8 data bytes.
		1	Note: The data length code of a message object must be defined the same as in all the corresponding objects with the same identifier at other nodes. When the message handler stores a data frame, it will write the DLC to the value given by the received message.
			Note: This bit is used to concatenate multiple message objects to build a FIFO Buffer. For single message objects (not belonging to a FIFO Buffer), this bit must always be set to one.
6-4	Reserved	0	These bits are always read as 0. Writes have no effect.
3-0			Data length code
		0-8	Data frame has 0-8 data bits.
		9-15	Data frame has 8 data bytes.
			Note: The data length code of a message object must be defined the same as in all the corresponding objects with the same identifier at other nodes. When the message handler stores a data frame, it will write the DLC to the value given by the received message.

23.4.22 IF1/IF2 Data A and Data B Registers (DCAN IF1DATA/DATB, DCAN IF2DATA/DATB)

The data bytes of CAN messages are stored in the IF1/IF2 registers in the following order:

1. In a CAN data frame, Data 0 is the first, and Data 7 is the last byte to be transmitted or received.
2. In CAN's serial bit stream, the MSB of each byte will be transmitted first.

The IF1/IF2 data A and data B registers (DCAN IF1DATA/DATB, DCAN IF2DATA/DATB) registers are shown in Figure 23-40, Figure 23-41, Figure 23-42 and Figure 23-43.

23.4.23 IF3 Observation Register (DCAN IF3OBS)

The IF3 register set can automatically be updated with received message objects without the need to initiate the transfer from message RAM by CPU (Additional information can be found in *Structure of Message Objects*).

The observation flags (Bits [4:0]) in the IF3 observation register are used to determine, which data sections of the IF3 interface register set have to be read in order to complete a DMA read cycle. After all marked data sections are read, the DCAN is enabled to update the IF3 interface register set with new data.

Any access order of single bytes or half-words is supported. When using byte or half-word accesses, a data section is marked as completed, if all bytes are read.

NOTE: If IF3 Update Enable is used and no Observation flag is set, the corresponding message objects will be copied to IF3 without activating the DMA request line and without waiting for DMA read accesses.

A write access to this register aborts a pending DMA cycle by resetting the DMA line and enables updating of IF3 interface register set with new data. To avoid data inconsistency, the DMA controller should be disabled before reconfiguring IF3 observation register.

The status of the current read-cycle can be observed via status flags (Bits [12:8]).

If an interrupt line is available for IF3, an interrupt will be generated by IF3Upd flag. See the device-specific data sheet for the availability of this interrupt source.

With this interrupt, the observation status bits and the IF3Upd bit could be used by the application to realize the notification about new IF3 content in polling or interrupt mode.

The IF3 observation register (DCAN IF3OBS) is shown in Figure 23-44 and described in Table 23-37.

Figure 23-44. IF3 Observation Register (DCAN IF3OBS)

LEGEND: R = Read only; -*n* = value after reset

Table 23-38. IF3 Mask Register (DCAN IF3MSK) Field Descriptions

Bit	Field	Value	Description
31	MXtd		Mask Extended Identifier
		0	The extended identifier bit (IDE) has no effect on the acceptance filtering.
		1	The extended identifier bit (IDE) is used for acceptance filtering.
			When 11-bit (“standard”) identifiers are used for a message object, the identifiers of received data frames are written into bits ID[28:18]. For acceptance filtering, only these bits together with mask bits Msk[28:18] are considered.
30	MDir		Mask Message Direction
		0	The message direction bit (Dir) has no effect on the acceptance filtering.
		1	The message direction bit (Dir) is used for acceptance filtering.
29	Reserved	0	These bits are always read as 0. Writes have no effect.
28-0	Msk[28:0]		Identifier Mask
		0	The corresponding bit in the identifier of the message object is not used for acceptance filtering (don't care).
		1	The corresponding bit in the identifier of the message object is used for acceptance filtering.

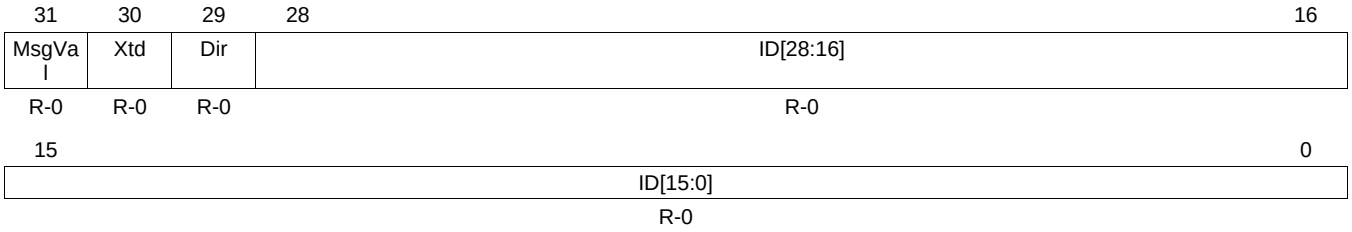
23.4.25 IF3 Arbitration Register (DCAN IF3ARB)

The IF3 arbitration register (DCAN IF3ARB) is shown in Figure 23-46 and described in Table 23-39.

Figure 23-46. IF3 Arbitration Register (DCAN IF3ARB)



LEGEND: R = Read only; WP = Write protected (protected by busy bit); -*n* = value after reset

Table 23-39. IF3 Arbitration Register (DCAN IF3ARB) Field Descriptions

Bit	Field	Value	Description
31	MsgVal		Message Valid
		0	The message object is ignored by the message handler.
		1	The message object is to be used by the message handler.
			The CPU should reset the MsgVal bit of all unused Messages Objects during the initialization before it resets bit Init in the CAN control register. This bit must also be reset before the identifier ID[28:0], the control bits Xtd, Dir or DLC[3:0] are modified, or if the messages object is no longer required.
30	Xtd		Extended Identifier
		0	The 11-bit (“standard”) Identifier is used for this message object.
		1	The 29-bit (“extended”) Identifier is used for this message object.
29	Dir		Message Direction
		0	Direction = receive: On TxRqst, a remote frame with the identifier of this message object is transmitted. On reception of a data frame with matching identifier, this message is stored in this message object.
		1	Direction = transmit: On TxRqst, the respective message object is transmitted as a data frame. On reception of a remote frame with matching identifier, the TxRqst bit of this message object is set (if RmtEn = 1).
28-0	Msk[28:0]		Message Identifier
		ID[28:0]	29-bit Identifier (“extended frame”)
		ID[28:18]	11-bit Identifier (“standard frame”)

23.4.28 Update Enable Registers (DCAN IF3UPD12 to IF3UPD78)

The automatic update functionality of the IF3 register set can be configured for each message object. A message object is enabled for automatic IF3 update, if the dedicated IF3UpdEn flag is set. This means that an active NewDat flag of this message object (e.g due to reception of a CAN frame) will trigger an automatic copy of the whole message object to IF3 register set.

The update enable registers (DCAN IF3UPD12 to IF3UPD78) are shown in Table 23-41 and described in Table 23-42.

NOTE: IF3 Update enable should not be set for transmit objects.

Table 23-41. Update Enable Registers (DCAN IF3UPD12 to IF3UPD78))

23.4.29 CAN TX I/O Control Register (DCAN TIOC)

The CAN_TX pin of the DCAN module can be used as general purpose IO pin if CAN function is not needed. The CAN TX I/O control register (DCAN TIOC) is shown in Figure 23-50 and described in Table 23-43.

NOTE: The values of the IO control registers are only writable if Init bit of the CAN control register is set.

NOTE: The OD, Func, Dir and Out bits of the CAN TX IO control register are forced to certain values when Init bit of CAN control register is reset (see bit descriptions).

Figure 23-50. CAN TX I/O Control Register (DCAN TIOC)

31	19	18	17	16
Reserved		PU	PD	OD
R-0		R/W-D	R/W-D	R/WP-0

15	3	2	1	0
Reserved	Func	Dir	Out	In
R-0	R/WP-0	R/WP-0	R/WP-0	R-U

LEGEND: R/W = Read/Write; R = Read only; WP = Protected Write (protected by Init bit), U = Undefined; D = Device dependent; -*n* = value after reset

Table 23-43. CAN TX I/O Control Register (DCAN TIOC) Field Descriptions

Bit	Field	Value	Description
31-19	Reserved	0	These bits are always read as 0. Writes have no effect.
18	PU		CAN_TX pull up/pull down select. This bit is only active when CAN_TX is configured to be an input.
		0	CAN_TX pull down is selected, when pull logic is active (PD = 0).
		1	CAN_TX pull up is selected, when pull logic is active(PD = 0).
17	PD		CAN_TX pull disable. This bit is only active when CAN_TX is configured to be an input.
		0	CAN_TX pull is active
		1	CAN_TX pull is disabled
16	OD		CAN_TX open drain enable. This bit is only active when CAN_TX is configured to be in GIO mode (TIOC.Func=0).
		0	The CAN_TX pin is configured in push/pull mode.
		1	The CAN_TX pin is configured in open drain mode.
			Forced to '0' if Init bit of CAN control register is reset.
15-4	Reserved	0	These bits are always read as 0. Writes have no effect.
3	Func		CAN_TX function. This bit changes the function of the CAN_TX pin
		0	CAN_TX pin is in GIO mode.
		1	CAN_TX pin is in functional mode (as an output to transmit CAN data).
			Forced to '1' if Init bit of CAN control register is reset.
2	Dir		CAN_TX data direction. This bit controls the direction of the CAN_TX pin when it is configured to be in GIO mode only (TIOC.Func=0)
		0	The CAN_TX pin is an input.
		1	The CAN_TX pin is an output
			Forced to '1' if Init bit of CAN control register is reset.

Copyright © 2011, Texas Instruments Incorporated

Table 23-43. CAN TX I/O Control Register (DCAN TIOC) Field Descriptions (continued)

Bit	Field	Value	Description
1	Out		CAN_TX data out write. This bit is only active when CAN_TX pin is configured to be in GIO mode (TIOC.Func = 0) and configured to be an output pin (TIOC.Dir = 1). The value of this bit indicates the value to be output to the CAN_TX pin.
		0	The CAN_TX pin is driven to logic low
		1	The CAN_TX pin is driven to logic high
			Forced to Tx output of the CAN core, if Init bit of CAN control register is reset.
0	In		CAN_TX data in
		0	The CAN_TX pin is at logic low
		1	The CAN_TX pin is at logic high
			Note: When CAN_TX pin is connected to a CAN transceiver, an external pullup resistor has to be used to ensure that the CAN bus will not be disturbed (e.g. while reset of the DCAN module).

Copyright © 2011, Texas Instruments Incorporated

23.4.30 CAN RX IO Control Register (DCAN RIOC)

The CAN_RX pin of the DCAN module can be used as general purpose IO pin if CAN function is not needed. The CAN RX I/O control register (DCAN RIOC) is shown in Figure 23-51 and described in Table 23-44.

NOTE: The values of the IO control registers are writable only if Init bit of CAN control register is set.

NOTE: The OD, Func and Dir bits of the CAN RX IO control register are forced to certain values when the Init bit of CAN control register is reset (see bit descriptions).

Figure 23-51. CAN RX IO control register (DCAN RIOC)

Table 23-44. CAN RX IO Control Register (DCAN RIOC) Field Descriptions (continued)

Bit	Field	Value	Description
1	Out		CAN_RX data out write. This bit is only active when CAN_RX pin is configured to be in GIO mode (TIOC.Func = 0) and configured to be an output pin (TIOC.Dir = 1). The value of this bit indicates the value to be output to the CAN_RX pin.
		0	The CAN_RX pin is driven to logic low
		1	The CAN_RX pin is driven to logic high
			Forced to Tx output of the CAN core, if Init bit of CAN control register is reset.
0	In		CAN_RX data in
		0	The CAN_RX pin is at logic low
		1	The CAN_RX pin is at logic high
			Note: When CAN_RX pin is connected to a CAN transceiver, an external pullup resistor has to be used to ensure that the CAN bus will not be disturbed (e.g. while reset of the DCAN module).

24.1 Introduction

This document is intended to provide programmers with a functional presentation of the Master/Slave Multichannel Serial Port Interface (McSPI) module. It also provides a register description and a module configuration example.

McSPI is a general-purpose receive/transmit master/slave controller that can interface with up to four slave external devices or one single external master. It allows a duplex, synchronous, serial communication between a CPU and SPI compliant external devices (Slaves and Masters).

24.1.1 McSPI Features

The general features of the SPI controller are:

- Buffered receive/transmit data register per channel (1 word deep)
- Multiple SPI word access with one channel using a FIFO
- Two DMA requests per channel, one interrupt line
- Single interrupt line, for multiple interrupt source events
- Serial link interface supports:
  - Full duplex / Half duplex
  - Multi-channel master or single channel slave operations
  - Programmable 1-32 bit transmit/receive shift operations.
  - Wide selection of SPI word lengths continuous from 4 to 32 bits
- Up to four SPI channels
- SPI word Transmit / Receive slot assignment based on round robin arbitration
- SPI configuration per channel (clock definition, enable polarity and word width)
- Clock generation supports:
  - Programmable master clock generation (operating from fixed 48-MHz functional clock input)
  - Selectable clock phase and clock polarity per chip select.

24.1.2 Unsupported McSPI Features

This device supports only two chip selects per module. Module wakeup during slave mode operation is not supported, as noted in *McSPI Clock and Reset Management*.

Table 24-1. Unsupported McSPI Features

Feature	Reason
Chip selects 2 and 3	Not pinned out
Slave mode wakeup	SWAKEUP not connected
Retention during power down	Module not synthesized with retention enabled

24.2 Integration

This device includes two instantiations of McSPI: SPI0 and SPI1. The McSPI module is a general-purpose receive/transmit master/slave controller that can interface with either up to four slave external devices or one single external master. Figure 24-1 shows the example of a system with multiple external slave SPI compatible devices and Figure 24-2 shows the example of a system with an external master.

24.2.1 McSPI Connectivity Attributes

The general connectivity attributes for the McSPI module are shown in Table 24-2.

Table 24-2. McSPI Connectivity Attributes

Attributes	Type
Power Domain	Peripheral Domain
Clock Domain	PD_PER_L4LS_GCLK (Interface/OCP) PD_PER_SPI_GCLK (Func)
Reset Signals	PER_DOM_RST_N
Idle/Wakeup Signals	Smart Idle
Interrupt Requests	1 interrupt to MPU subsystem and PRUSS (McSPI0INT) 1 interrupt to MPU subsystem only (McSPI1INT)
DMA Requests	4 DMA requests per instance to EDMA • 1 RX request for CS0 (SPIREVT0) • 1 TX request for CS0 (SPIXEVT0) • 1 RX request for CS1 (SPIREVT1) • 1 TX request for CS1 (SPIXEVT1)
Physical Address	L4 Peripheral slave port

24.2.2 McSPI Clock and Reset Management

The SPI module clocks can be woken up in two manners: by the SPI module itself using the SWAKEUP signal (refer to the module functional spec for detailed conditions), or directly from an external SPI master device by detecting an active low level on its chip select input pin (CS0n) using a GPIO attached to that device pin. Neither of these methods is supported on the device.

Table 24-3. McSPI Clock Signals

Clock Signal	Max Freq	Reference / Source	Comments
CLK Interface clock	100 MHz	CORE_CLKOUTM4 / 2	pd_per_l4ls_gclk From PRCM
CLKSPIREF Functional clock	48 MHz	PER_CLKOUTM2 / 4	pd_per_spi_gclk From PRCM

24.2.3 McSPI Pin List

The McSPI interface pins are summarized in Table 24-4.

Table 24-4. McSPI Pin List

Pin	Type	Description
SPI*x*_SCLK	I/O	SPI serial clock (output when master, input when slave)
SPI*x*_D0	I/O	Can be configured as either input or output (MOSI or MISO)
SPI*x*_D1	I/O	Can be configured as either input or output (MOSI or MISO)
SPI*x*_CS0	I/O	SPI chip select 0 output when master, input when slave (active low)
SPI*x*_CS1	O	SPI chip select 1 output when master, input when slave (active low)

Copyright © 2011, Texas Instruments Incorporated

24.3 Functional Description

24.3.1 SPI Interface

This section lists the name and description of the SPI interface used for connection to external SPI compliant devices. McSPI has a total of seven external SPI signals shown in Table 24-5.

Table 24-5. McSPI Interface Pins

Pin	Type	Description
SPI_SCLK	I/O	SPI serial clock (output when master, input when slave)
SPI_D0	I/O	Can be configured as either input or output (MOSI or MISO)
SPI_D1	I/O	Can be configured as either input or output (MOSI or MISO)
$\overline{\text{SPI_CS0}}$	I/O	SPI chip select 0 output when master, input when slave (active low)
$\overline{\text{SPI_CS1}}$	I/O	SPI chip select 0 output when master, input when slave (active low)
$\overline{\text{SPI_CS2}}$	I/O	SPI chip select 2 output when master, input when slave (active low)
$\overline{\text{SPI_CS3}}$	I/O	SPI chip select 3 output when master, input when slave (active low)

24.3.2 SPI Transmission

This section describes the transmissions supported by McSPI. The SPI protocol is a synchronous protocol that allows a master device to initiate serial communication with a slave device. Data is exchanged between these devices. A slave select line (SPIEN) can be used to allow selection of an individual slave SPI device. Slave devices that are not selected do not interfere with SPI bus activities. Connected to multiple external devices, McSPI exchanges data with a single SPI device at a time through two main modes:

- Two data pins interface mode. (See Section 24.3.2.1)
- Single data pin interface mode (recommended for half-duplex transmission). (See Section 24.3.2.2)

The flexibility of McSPI allows exchanging data with several formats through programmable parameters described in Section 24.3.2.3.

Copyright © 2011, Texas Instruments Incorporated

24.3.2.1 Two Data Pins Interface Mode

The two data pins interface mode, allows a full duplex SPI transmission where data is transmitted (shifted out serially) and received (shifted in serially) simultaneously on separate data lines SPIDAT [0] and SPIDAT [1]. Data leaving the master exits on transmit serial data line also known as MOSI: MasterOutSlaveIn. Data leaving the slave exits on the receive data line also known as MISO: MasterInSlaveOut.

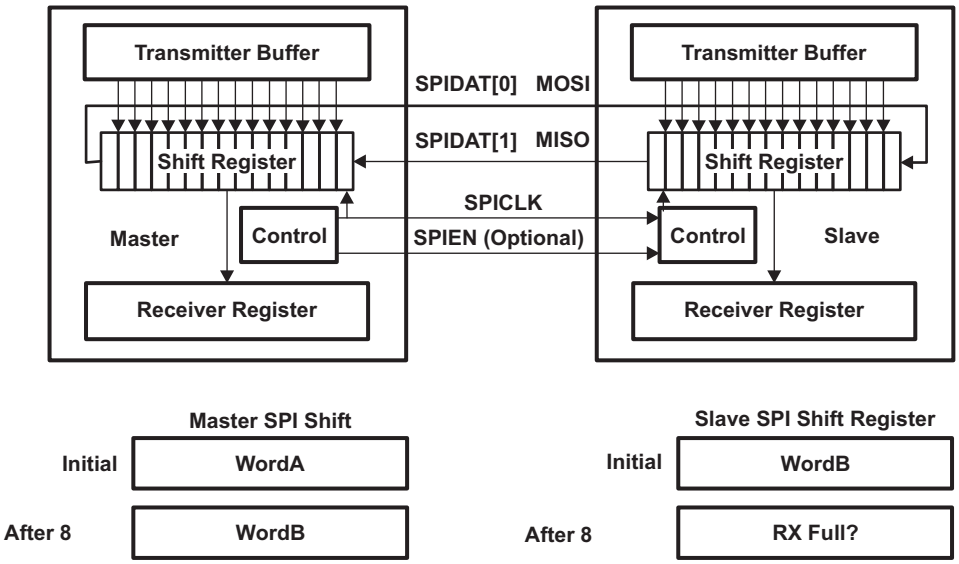
McSPI has a unified SPI port control: SPIDAT [1:0] can be independently configured as receive or transmit lines. The user has the responsibility to program which data line to use and in which direction (receive or transmit), according to the external slave/master connection.

The serial clock (SPICLK) synchronizes shifting and sampling of the information on the two serial data lines (SPIDAT [1:0]). Each time a bit is transferred out from the Master, one bit is transferred in from Slave.

Figure 24-3 shows an example of a full duplex system with a Master device on the left and a Slave device on the right. After 8 cycles of the serial clock SPICLK, the WordA has been transferred from the master to the slave. At the same time, the 8-bit WordB has been transferred from the slave to the master.

When referring to the master device, the control block transmits the clock SPICLK and the enable signal SPIEN (optional, see Section 24.5.7, *McSPI_MODULECTRL*).

Figure 24-3. SPI Full-Duplex Transmission



24.3.2.2 Single Data Pin Interface Mode

In single data pin interface mode, under software control, a single data line is used to alternatively transmit and receive data (Half duplex transmission).

McSPI has a unified SPI port control: SPIDAT [1:0] can be independently configured as receive or transmit lines. The user has the responsibility to program which data line to use and in which direction (receive or transmit), according to the external slave/master connection.

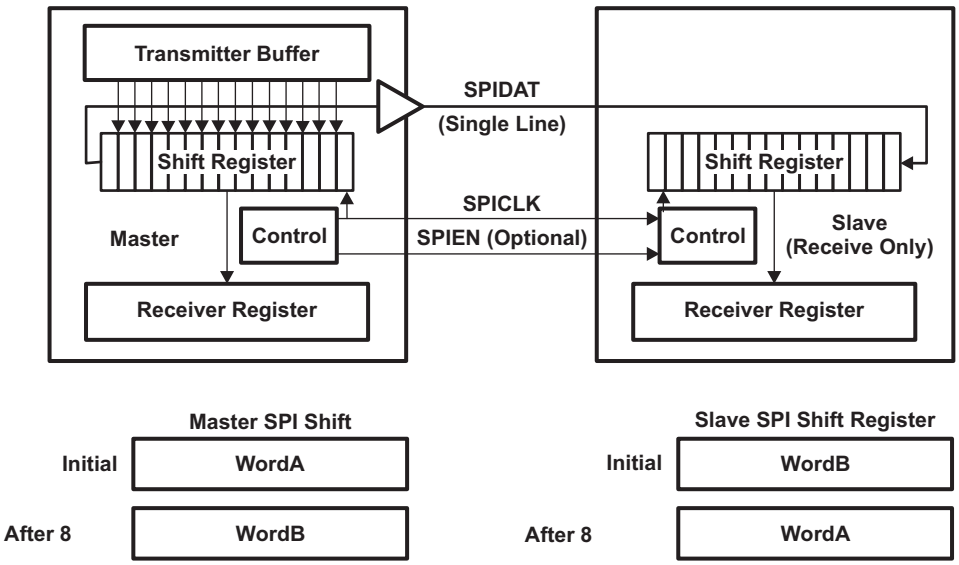
As for a full duplex transmission, the serial clock (SPICLK) synchronizes shifting and sampling of the information on the single serial data line.

Copyright © 2011, Texas Instruments Incorporated

24.3.2.2.1 Example With a Receive-Only Slave

Figure 24-4 shows a half duplex system with a Master device on the left and a receive-only Slave device on the right. Each time a bit is transferred out from the Master, one bit is transferred in the Slave. After 8 cycles of the serial clock SPICLK, the 8-bit WordA has been transferred from the master to the slave.

Figure 24-4. SPI Half-Duplex Transmission (Receive-only Slave)



24.3.2.2.2 Example With a Transmit-Only Slave

Figure 24-5 shows a half duplex system with a Master device on the left and a transmit-only Slave device on the right. Each time a bit is transferred out from the Slave, one bit is transferred in the Master. After 8 cycles of the serial clock SPICLK, the 8-bit WordA has been transferred from the slave to the master.

Figure 24-5. SPI Half-Duplex Transmission (Transmit-Only Slave)

24.3.2.3 Transfer Formats

This section describes the transfer formats supported by McSPI.

The flexibility of McSPI allows setting the parameters of the SPI transfer:

- SPI word length
- SPI enable generation programmable
- SPI enable assertion
- SPI enable polarity
- SPI clock frequency
- SPI clock phase
- SPI clock polarity

The consistency between SPI word length, clock phase and clock polarity of the master SPI device and the communicating slave device remains under software responsibility.

24.3.2.3.1 Programmable Word Length

McSPI supports any SPI word from 4 to 32 bits long.

The SPI word length can be changed between transmissions to allow a master device to communicate with peripheral slaves having different requirements.

24.3.2.3.2 Programmable SPI Enable Generation

McSPI is able to generate or not the SPI enable, if management of chip select is de-asserted a point to point connection is mandatory. Only a single master of slave device can be connected to the SPI bus.

24.3.2.3.3 Programmable SPI Enable (SPIEN)

The polarity of the SPIEN signals is programmable. SPIEN signals can be active high or low.

The assertion of the SPIEN signals is programmable: SPIEN signals can be manually asserted or can be automatically asserted.

Two consecutive words for two different slave devices may go along with active SPIEN signals with different polarity.

24.3.2.3.4 Programmable SPI Clock (SPICLK)

The phase and the polarity of the SPI serial clock are programmable when McSPI is a SPI master device or a SPI slave device. The baud rate of the SPI serial clock is programmable when McSPI is a SPI master.

When McSPI is operating as a slave, the serial clock SPICLK is an input from the master.

24.3.2.3.5 Bit Rate

In Master Mode, an internal reference clock CLKSPIREF is used as an input of a programmable divider to generate bit rate of the serial clock SPICLK. Granularity of this clock divider can be changed.

Copyright © 2011, Texas Instruments Incorporated

24.3.2.3.6 Polarity and Phase

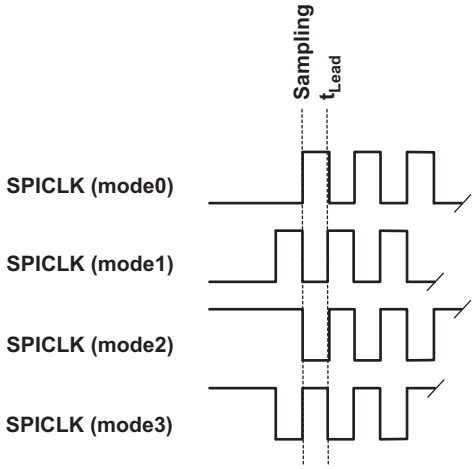
McSPI supports four sub-modes of the SPI format transfer that depend on the polarity (POL) and the phase (PHA) of the SPI serial clock (SPICLK). Table 24-6 and Figure 24-6 show a summary of the four sub-modes. Software selects one of four combinations of serial clock phase and polarity.

Two consecutive SPI words for two different slave devices may go along with active SPICLK signal with different phase and polarity.

Table 24-6. Phase and Polarity Combinations

Polarity (POL)	Phase (PHA)	SPI Mode	Comments
0	0	mode0	SPICLK active high and sampling occurs on the rising edge.
0	1	mode1	SPICLK active high and sampling occurs on the falling edge.
1	0	mode2	SPICLK active low and sampling occurs on the falling edge.
1	1	mode3	SPICLK active low and sampling occurs on the rising edge.

Figure 24-6. Phase and Polarity Combinations



Copyright © 2011, Texas Instruments Incorporated

24.3.2.3.7 Transfer Format With PHA = 0

This section describes the concept of a SPI transmission with the SPI mode0 and the SPI mode2.

In the transfer format with PHA = 0, SPIEN is activated a half cycle of SPICLK ahead of the first SPICLK edge.

In both master and slave modes, McSPI drives the data lines at the time of SPIEN is asserted.

Each data frame is transmitted starting with the MSB. At the extremity of both SPI data lines, the first bit of SPI word is valid a half-cycle of SPICLK after the SPIEN assertion.

Therefore, the first edge of the SPICLK line is used by the master to sample the first data bit sent by the slave. On the same edge, the first data bit sent by the master is sampled by the slave.

On the next SPICLK edge, the received data bit is shifted into the shift register, and a new data bit is transmitted on the serial data line.

This process continues for a total of pulses on the SPICLK line defined by the SPI word length programmed in the master device, with data being latched on odd numbered edges and shifted on even numbered edges.

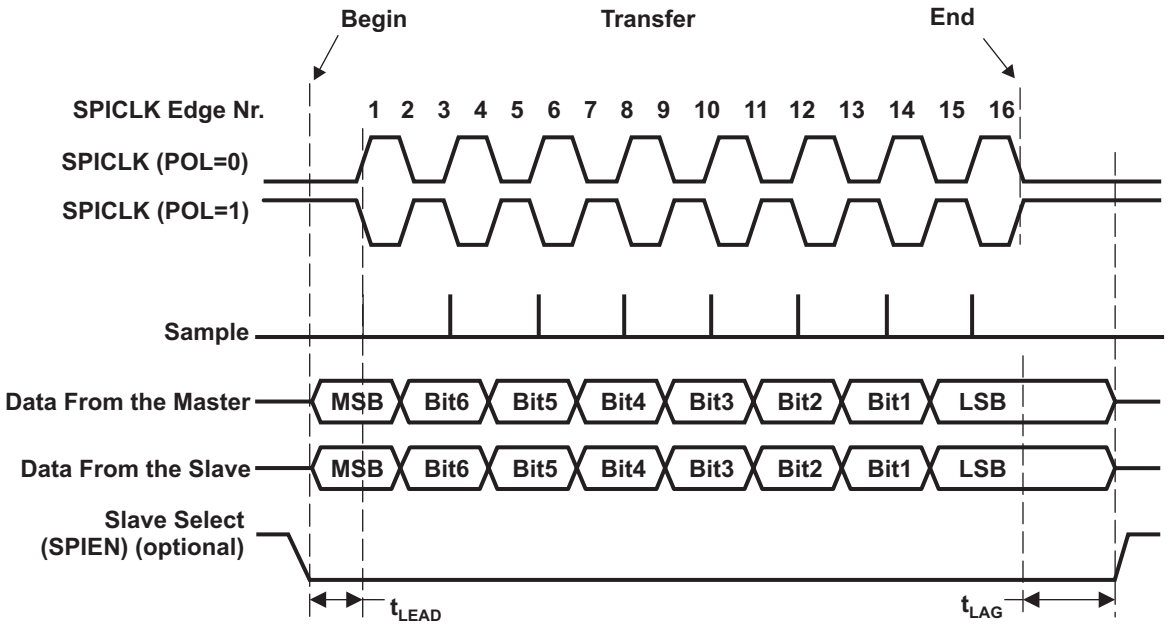
Figure 24-7 is a timing diagram of a SPI transfer for the SPI mode0 and the SPI mode2, when McSPI is master or slave, with the frequency of SPICLK equals to the frequency of CLKSPIREF. It should not be used as a replacement for SPI timing information and requirements detailed in the data manual.

When McSPI is in slave mode, if the SPIEN line is not de-asserted between successive transmissions then the content of the Transmitter register is not transmitted, instead the last received SPI word is transmitted.

In master mode, the SPIEN line must be negated and reasserted between each successive SPI word. This is because the slave select pin freezes the data in its shift register and does not allow it to be altered if PHA bit equals 0.

In 3-pin mode without using the SPIEN signal, the controller provides the same waveform but with SPIEN forced to low state. In slave mode SPIEN is useless

Figure 24-7. Full Duplex Single Transfer Format with PHA = 0



Copyright © 2011, Texas Instruments Incorporated

24.3.2.3.8 Transfer Format With PHA = 1

This section describes SPI full duplex transmission with the SPI mode1 and the SPI mode3.

In the transfer format with PHA = 1, SPIEN is activated a delay (t_{Lead}) ahead of the first SPICLK edge.

In both master and slave modes, McSPI drives the data lines on the first SPICLK edge.

Each data frame is transmitted starting with the MSB. At the extremity of both SPI data lines, the first bit of SPI word is valid on the next SPICLK edge, a half-cycle later of SPICLK. It is the sampling edge for both the master and slave.

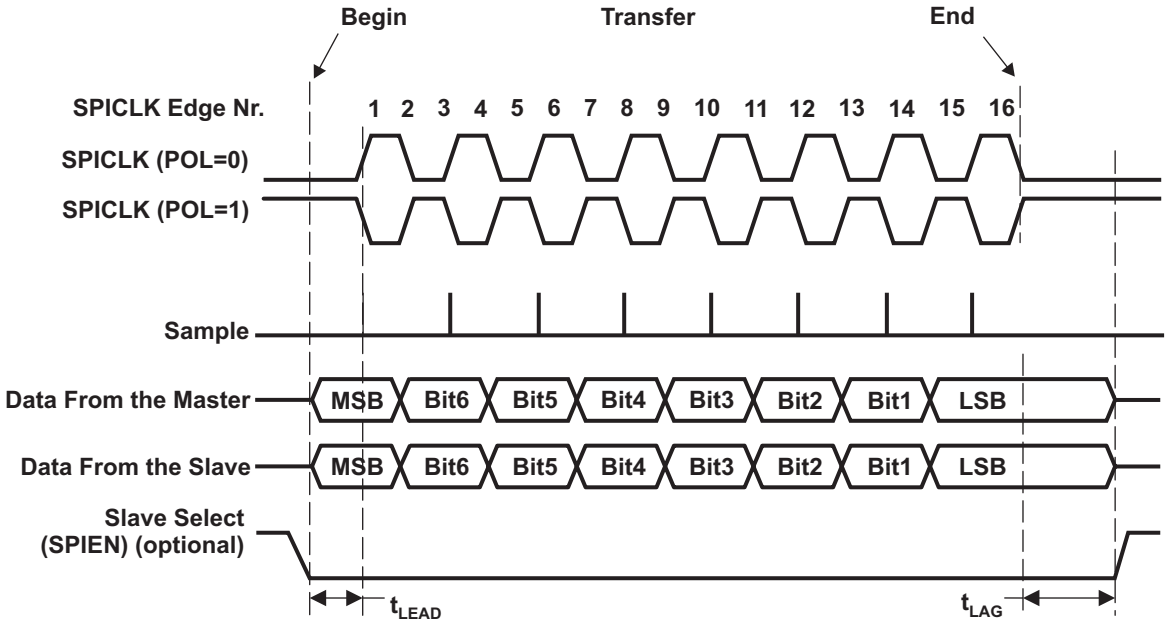
When the third edge occurs, the received data bit is shifted into the shift register. The next data bit of the master is provided to the serial input pin of the slave.

This process continues for a total of pulses on the SPICLK line defined by the word length programmed in the master device, with data being latched on even numbered edges and shifted on odd numbered edges.

Figure 24-8 is a timing diagram of a SPI transfer for the SPI mode1 and the SPI mode3, when McSPI is master or slave, with the frequency of SPICLK equals to the frequency of CLKSPIREF. It should not be used as a replacement for SPI timing information and requirements detailed in the data manual.

The SPIEN line may remain active between successive transfers. In 3-pin mode without using the SPIEN signal, the controller provides the same waveform but with SPIEN forced to low state. In slave mode SPIEN is useless.

Figure 24-8. Full Duplex Single Transfer Format With PHA = 1



Copyright © 2011, Texas Instruments Incorporated

24.3.3 Master Mode

McSPI is in master mode when the bit MS of the register MCSPI_MODULCTRL is cleared.

In master mode McSPI supports multi-channel communication with up to 4 independent SPI communication channel contexts. McSPI initiates a data transfer on the data lines (SPIDAT [1;0]) and generates clock (SPICLK) and control signals (SPIEN) to a single SPI slave device at a time.

24.3.3.1 Dedicated Resources Per Channel

In the following sections, the letter “I” indicates the channel number that can be 0, 1, 2 or 3. Each channel has the following dedicated resources:

- Its own channel enable, programmable with the bit EN of the register MCSPI_CH(I)CTRL. Disabling the channel, outside data word transmission, remains under user responsibility.
- Its own transmitter register MCSPI_TX on top of the common shift register. If the transmitter register is empty, the status bit TXS of the register MCSPI_CH(I)STAT is set.
- Its own receiver register MCSPI_RX on top of the common shift register. If the receiver register is full, the status bit RXS of the register MCSPI_CH(I)STAT is set.
- A fixed SPI ENABLE line allocation (SPIEN[i] port for channel “I”), SPI enable management is optional.
- Its own communication configuration with the following parameters via the register (I)CONF
  - Transmit/Receive modes, programmable with the bit TRM.
  - Interface mode (Two data pins or Single data pin) and data pins assignment, both programmable with the bits IS and DPE.
  - SPI word length, programmable with the bits WL.
  - SPIEN polarity, programmable with the bit EPOL.
  - SPIEN kept active between words, programmable with the bit FORCE.
  - Turbo mode, programmable with the bit TURBO.
  - SPICLK frequency, programmable with the bit CLKD, the granularity of clock division can be changed using CLKG bit, the clock ratio is then concatenated with MCSPI_CHCTRL[EXTCLK] value.
  - SPICLK polarity, programmable with the bit POL
  - SPICLK phase, programmable with the bit PHA.
  - Start bit polarity, programmable with the bit SBPOL
  - Use a FIFO Buffer or not (see the following note), programmable with FFER and FFEW, depending on transfer mode, (MCSPI_CH(I)CONF[TRM]).
- Two DMA requests events, read and write, to synchronize read/write accesses of the DMA controller with the activity of McSPI. The DMA requests are enabled with the bits DMAR and DMAW.
- Three interrupts events

Note: When more than one channel has an FIFO enable bit field (FFER or FFEW) set, the FIFO will not be used on any channel. Software must ensure that only one enabled channel is configured to use the FIFO buffer.

The transfers will use the latest loaded parameters of the register MCSPI_CH(I)CONF.

The configuration parameters SPIEN polarity, Turbo mode, SPICLK phase and SPICLK polarity can be loaded in the MCSPI_CH(I)CONF register only when the channel is disabled. The user has the responsibility to change the other parameters of the MCSPI_CH(I)CONF register when no transfer occurs on the SPI interface.

Copyright © 2011, Texas Instruments Incorporated

24.3.3.2 Interrupt Events in Master Mode

In master mode, the interrupt events related to the transmitter register state are TX_empty and TX_underflow. The interrupt event related to the receiver register state is RX_full.

24.3.3.2.1 TX_empty

The event TX_empty is activated when a channel is enabled and its transmitter register becomes empty (transient event). Enabling channel automatically raises this event, except for the Master receive only mode. (See Section 24.3.3.5). When the FIFO buffer is enabled (MCSPI_CH(I)CONF[FFEW] set to 1), the TX_empty is asserted as soon as there is enough space in the buffer to write a number of bytes defined by MCSPI_XFERLEVEL[AEL].

Transmitter register must be loaded to remove the source of the interrupt and the TX_empty interrupt status bit must be cleared for interrupt line de-assertion (if event enabled as interrupt source) . (See Section 24.3.5).

When FIFO is enabled, no new TX_empty event will be asserted as soon as CPU has not performed the number of write into transmitter register defined by MCSPI_XFERLEVEL[AEL]. It is the responsibility of CPU to perform the right number of writes.

24.3.3.2.2 TX_underflow

The event TX_underflow is activated when the channel is enabled and if the transmitter register or FIFO is empty (not updated with new data) at the time of shift register assignment.

The TX_underflow is a harmless warning in master mode.

To avoid having TX_underflow event at the beginning of a transmission, the event TX_underflow is not activated when no data has been loaded into the transmitter register since channel has been enabled.

To avoid having a TX_underflow event, the Transmit Register (MCSPI_TX(i)) should be loaded as infrequently as possible.

TX_underflow interrupt status bit must be cleared for interrupt line de-assertion (if event enable as interrupt source).

Note: When more than one channel has an FIFO enable bit field (FFER or FFEW) set, the FIFO will not be used on any channel. Software must ensure that only one enabled channel is configured to use the FIFO buffer.

24.3.3.2.3 RX_ full

The event RX_full is activated when channel is enabled and receiver register becomes filled (transient event). When FIFO buffer is enabled (MCSPI_CH(I)CONF[FFER] set to 1), the RX_full is asserted when the number of bytes in the buffer equals the level defined by MCSPI_XFERLEVEL[AFL].

Receiver register must be read to remove source of interrupt and RX_full interrupt status bit must be cleared for interrupt line de-assertion (if event enabled as interrupt source).

When the FIFO is enabled, no new RX_FULL event will be asserted once the CPU has read the number of bytes defined by MCSPI_XFERLEVEL[AFL]. It is the responsibility of the CPU to perform the correct number of read operations.

24.3.3.2.4 End of Word Count

The event end of word (EOW) count is activated when channel is enabled and configured to use the built-in FIFO. This interrupt is raised when the controller had performed the number of transfer defined in MCSPI_XFERLEVEL[WCNT] register. If the value was programmed to 0000h, the counter is not enabled and this interrupt is not generated.

The EOW count interrupt also indicates that the SPI transfer has halted on the channel using the FIFO buffer.

The EOW interrupt status bit must be cleared for interrupt line de-assertion (if event enable as interrupt source).

Copyright © 2011, Texas Instruments Incorporated

24.3.3.3 Master Transmit and Receive Mode

This mode is programmable per channel (bit TRM of register MCSPI_CH(I)CONF).

The channel access to the shift registers, for transmission/reception, is based on its transmitter and receiver register state and round robin arbitration.

The channel that meets the rules below is included in the round robin list of already active channels scheduled for transmission and/or reception. The arbiter skips the channel that does not meet the rules and search for the next following enabled channel, in rotation.

Rule 1: Only enabled channels (bit EN of the register MCSPI_CH(I)CTRL), can be scheduled for transmission and/or reception.

Rule 2: An enabled channel can be scheduled if its transmitter register is not empty (bit TXS of the register MCSPI_CH(I)STAT) or its FIFO is not empty when the buffer is used for the corresponding channel (bit FFE of the register MCSPI_CH(I)STAT) at the time of shift register assignment. If the transmitter register or FIFO is empty, at the time of shift register assignment, the event TX_underflow is activated and the next enabled channel with new data to transmit is scheduled. (See also transmit only mode).

Rule 3: An enabled channel can be scheduled if its receive register is not full (bit RXS of the register MCSPI_CH(I)STAT)) or its FIFO is not full when the buffer is used for the corresponding channel (bit FFF of the register MCSPI_CH(I)STAT) at the time of shift register assignment. (See also receive only mode). Therefore the receiver register of FIFO cannot be overwritten. The RX_overflow bit, in the MCSPI_IRQSTATUS register is never set in this mode.

On completion of SPI word transfer (bit EOT of the register MCSPI_CH(I)STAT is set) the updated transmitter register for the next scheduled channel is loaded into the shift register. This bit is meaningless when using the Buffer for this channel. The serialization (transmit and receive) starts according to the channel communication configuration. On serialization completion the received data is transferred to the channel receive register.

The built-in FIFO is available in this mode and if configured in one data direction, transmit or receive, then the FIFO is seen as a unique FFNBYTE bytes buffer. If configured in both data directions, transmit and receive, then the FIFO is split into two separate FFNBYTE/2 bytes buffer with their own address space management. In this last case, the definition of AEL and AFL levels is based on FFNBYTE/2 bytes and is under CPU responsibility.

24.3.3.4 Master Transmit-Only Mode

This mode eliminates the need for the CPU to read the receiver register (minimizing data movement) when only transmission is meaningful.

The master transmit only mode is programmable per channel (bits TRM of the register MCSPI_CH(I)CONF).

In master transmit only mode, transmission starts after data is loaded into the transmitter register.

Rule 1 and **Rule 2**, defined above, are applicable in this mode.

Rule 3, defined above, is not applicable: In master transmit only mode, the receiver register or FIFO state “full” does not prevent transmission, and the receiver register is always overwritten with the new SPI word. This event in the receiver register is not significant when only transmission is meaningful. So, the RX_overflow bit, in the MCSPI_IRQSTATUS register is never set in this mode.

The McSPI module automatically disables the RX_full interrupt status. The corresponding interrupt request and DMA Read request are not generated in master transmit only mode.

The status of the serialization completion is given by the bit EOT of the register MCSPI_CH(I)STAT. This bit is meaningless when using the Buffer for this channel.

The built-in FIFO is available in this mode and can be configured with FFEW bit field in the MCSPI_CH(I)CONF register, then the FIFO is seen as a unique FFNBYTE bytes buffer.

Copyright © 2011, Texas Instruments Incorporated

24.3.3.5 Master Receive-Only Mode

This mode eliminates the need for the CPU to refill the transmitter register (minimizing data movement) when only reception is meaningful.

The master receive mode is programmable per channel (bits TRM of the register MCSPI_CH(I)CONF).

The master receive only mode enables channel scheduling only on empty state of the receiver register.

Rule 1 and **Rule 3**, defined above, are applicable in this mode.

Rule 2, defined above, is not applicable: In master receive only mode, after the first loading of the transmitter register of the enabled channel, the transmitter register state is maintained as full. The content of the transmitter register is always loaded into the shift register, at the time of shift register assignment. So, after the first loading of the transmitter register, the bits TX_empty and TX_underflow, in the MCSPI_IRQSTATUS register are never set in this mode.

The status of the serialization completion is given by the bit EOT of the register MCSPI_CH(I)STAT. The bit RX_full in the MCSPI_IRQSTATUS register is set when a received data is loaded from the shift register to the receiver register. This bit is meaningless when using the Buffer for this channel.

The built-in FIFO is available in this mode and can be configured with FFER bit field in the MCSPI_CH(I)CONF register, then the FIFO is seen as a unique FFNBYTE byte buffer.

24.3.3.6 Single-Channel Master Mode

When the SPI is configured as a master device with a single enabled channel, the assertion of the SPIM_CSX signal can be controlled in two different ways:

- In 3 pin mode : MCSPI_MODULCTRL[1] PIN34 and MCSPI_MODULCTRL[0] SINGLE bit are set to 1, the controller transmit SPI word as soon as transmit register or FIFO is not empty.
- In 4 pin mode : MCSPI_MODULCTRL[1] PIN34 bit is cleared to 0 and MCSPI_MODULCTRL[0] SINGLE bit is set to 1, SPIEN assertion/deassertion controlled by Software. (See Section 24.3.3.6.1) using the MCSPI_CHxCONF[20] FORCE bit.

24.3.3.6.1 Programming Tips When Switching to Another Channel

When a single channel is enabled and data transfer is ongoing:

- Wait for completion of the SPI word transfer (bit EOT of the register MCSPI_CH(I)STAT is set) before disabling the current channel and enabling a different channel.
- Disable the current channel first, and then enable the other channel.

24.3.3.6.2 Keep SPIEN Active Mode (Force SPIEN)

Continuous transfers are manually allowed by keeping the SPIEN signal active for successive SPI words transfer. Several sequences (configuration/enable/disable of the channel) can be run without deactivating the SPIEN line. This mode is supported by all channels and any master sequence can be used (transmit-receive, transmit-only, receive-only).

Keeping the SPIEN active mode is supported when:

- A single channel is used (bit MCSPI_MODULCTRL[Single] is set to 1).
- Transfer parameters of the transfer are loaded in the configuration register (MCSPI_CH(I)CONF) in the appropriate channel.

  The state of the SPIEN signal is programmable.
  - Writing 1 into the bit FORCE of the register MCSPI_CH(I)CONF drives high the SPIEN line when MCSPI_CHCONF(I)[EPOL] is set to zero, and drives it low when MCSPI_CHCONF(I)[EPOL] is set.
  - Writing 0 into the bit FORCE of the register MCSPI_CH(I)CONF drives low the SPIEN line when MCSPI_CHCONF(I)[EPOL] is set to zero, and drives it high when MCSPI_CHCONF(I)[EPOL] is set.
- A single channel is enabled (MCSPI_CH(I)CTRL[En] set to 1) . The first enabled channel activates the SPIEN line.

Copyright © 2011, Texas Instruments Incorporated

Once the channel is enabled, the SPIEN signal is activated with the programmed polarity.

As in multi-channel master mode, the start of the transfer depends on the status of the transmitter register, the status of the receiver register and the mode defined by the bits TRM in the configuration register (transmit only, receive only or transmit and receive) of the enabled channel.

The status of the serialization completion of each SPI word is given by the bit EOT of the register MCSPI_CH(I)STAT. The bit RX_full in the MCSPI_IRQSTATUS register is set when a received data is loaded from the shift register to the receiver register.

A change in the configuration parameters is propagated directly on the SPI interface. If the SPIEN signal is activated the user must insure that the configuration is changed only between SPI words, in order to avoid corrupting the current transfer.

NOTE: The SPIEN polarity, the SPICLK phase and SPICLK polarity must not be modified when the SPIEN signal is activated. The Transmit/Receive mode, programmable with the bit TRM can be modified only when the channel is disabled. The channel can be disabled and enabled while the SPIEN signal is activated.

The delay between SPI words that requires the connected SPI slave device to switch from one configuration (Transmit only for instance) to another (receive only for instance) must be handled under software responsibility.

At the end of the last SPI word, the channel must be deactivated (MCSPI_CH(I)CTRL[En] is cleared to 0) and the SPIEN can be forced to its inactive state (MCSPI_CH(I)CONF[Force]).

Figure 24-9 and Figure 24-10 show successive transfers with SPIEN kept active low with a different configuration for each SPI word in respectively single data pin interface mode and two data pins interface mode. The arrows indicate when the channel is disabled before a change in the configuration parameters and enabled again.

Figure 24-9. Continuous Transfers With SPIEN Maintained Active (Single-Data-Pin Interface Mode)

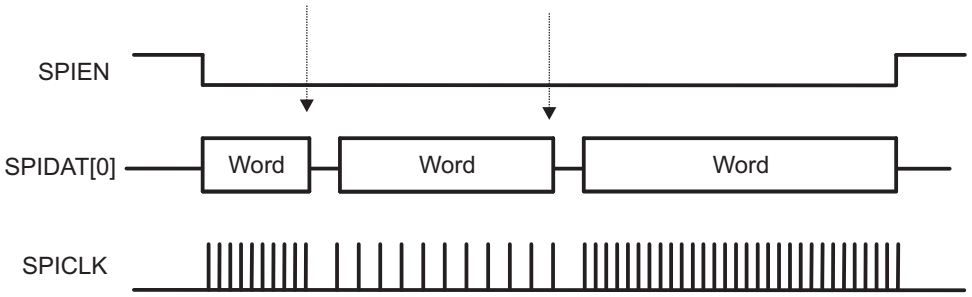


Figure 24-10. Continuous Transfers With SPIEN Maintained Active (Dual-Data-Pin Interface Mode)

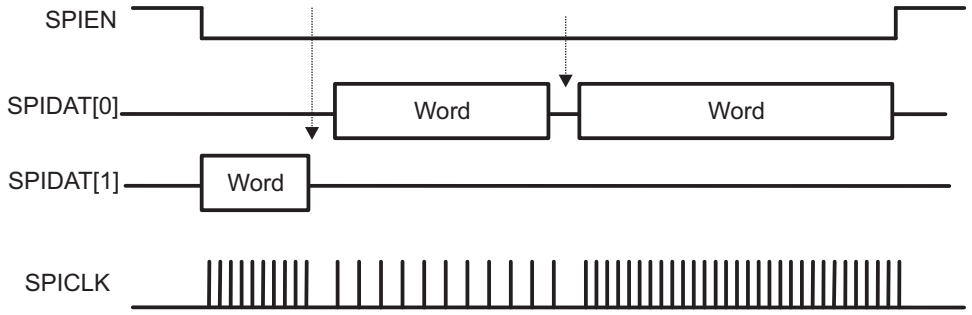

Copyright © 2011, Texas Instruments Incorporated

NOTE: The turbo mode is also supported for the Keep SPIEN active mode when the following conditions are met:

- A single channel will be explicitly used (bit MCSPI_MODULCTRL[Single] is set to 1).
- The turbo mode is enabled in the configuration of the channel (bit Turbo of the register (i)CONF).

24.3.3.6.3 Turbo Mode

The purpose of the Turbo mode is to improve the throughput of the SPI interface when a single channel is enabled, by allowing transfers until the shift register and the receiver register are full.

This mode is programmable per channel (bit Turbo of the register (I)CONF). When several channels are enabled, the bit Turbo of the registers MCSPI_CH(I)CONF has no effect, and the channel access to the shift registers remains as described in Section 24.3.3.3.

In Turbo mode, **Rule 1** and **Rule 2** defined in Section 24.3.3.3 are applicable but Rule 3 is not applicable. An enabled channel can be scheduled if its receive register is full (bit RXS of the register MCSPI_CH(I)STAT) at the time of shift register assignment until the shift register is full.

In Turbo mode, **Rule 1** and **Rule 2** defined in Section 24.3.3.3 are applicable but Rule 3 is not applicable. An enabled channel can be scheduled if its receive register is full (bit RXS of the register MCSPI_CH(I)STAT) at the time of shift register assignment until the shift register is full.

The receiver register cannot be overwritten in turbo mode. In consequence the RX_overflow bit, in MCSPI_IRQSTATUS register is never set in this mode.

24.3.3.7 Start Bit Mode

The purpose of the start bit mode is to add an extended bit before the SPI word transmission specified by word length WL. This feature is only available in master mode.

This mode is programmable per channel (bit Start bit enable SBE of the register MCSPI_CH(I)CONF).

The polarity of the extended bit is programmable per channel and it indicates whether the next SPI word must be handled as a command when SBPOL is cleared to 0 or as a data or a parameter when SBPOL is set to 1. Moreover start bit polarity SBPOL can be changed dynamically during start bit mode transfer without disabling the channel for reconfiguration, in this case you have the responsibility to configure the SBPOL bit before writing the SPI word to be transmitted in TX register.

The start bit mode could be used at the same time as turbo mode and/or manual chip select mode. In this case only one channel could be used, no round-robin arbitration is possible.

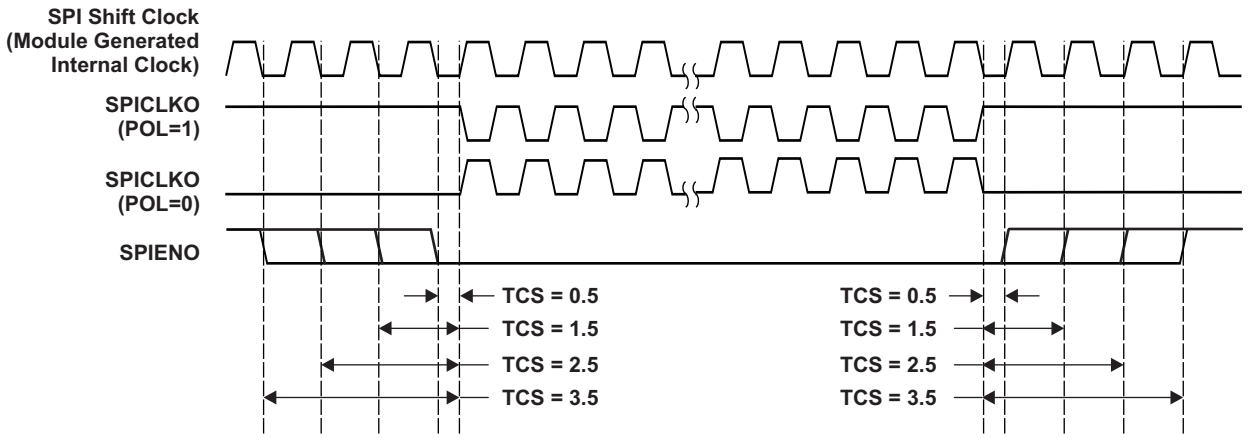
24.3.3.8 Chip-Select Timing Control

The chip select timing control is only available in master mode with automatic chip select generation (FORCE bit field is cleared to 0), to add a programmable delay between chip select assertion and first clock edge or chip select removal and last clock edge. The option is available only in 4 pin mode MCSPI_MODULCTRL[1] PIN34 is cleared to 0.

This mode is programmable per channel (bit TCS of the register MCSPI_CH(I)CONF). Figure 24-12 shows the chip-select SPIEN timing control.

Figure 24-12. Chip-Select SPIEN Timing Controls



NOTE: Because of the design implementation for transfers using a clock divider ratio set to 1 (clock bypassed), a half cycle must be added to the value between chip-select assertion and the first clock edge with PHA = 1 or between chip-select removal and the last clock edge with PHA = 0.

With an odd clock divider ratio which occurs when granularity is one clock cycle, that means that MCSPI_CH(I)CONF[CLKG] is set to 1 and MCSPI_CH(I)CONF[CLKD] has an even value, the clock duty cycle is not 50%, then one of the high level or low level duration is selected to be added to TCS delay.

Table 24-7 summarizes all delays between chip select and first (setup) or last (hold) clock edge.

In 3-pin mode this option is useless, the chip select SPIEN is forced to low state.

Table 24-7. Chip Select ↔ Clock Edge Delay Depending on Configuration

Clock Ratio F_{ratio}	Clock Phase PHA	Chip Select ↔ Clock Edge Delay	
		Setup	Hold
1	0	T_ref × (TCS + ½)	T_ref × (TCS + 1)
	1	T_ref × (TCS + 1)	T_ref × (TCS + ½)
Even ≥ 2	x	T_ref × F_{ratio} × (TCS + ½)	T_ref × F_{ratio} × (TCS + ½)
Odd ≥ 3 (only with MCSPI_CH(I)CONF[CLKG] set to 1	0	T_ref × [{F_{ratio} × TCS) + (F_{ratio} + ½)]	T_ref × [{F_{ratio} × TCS) + (F_{ratio} + ½)]
	1	T_ref × [{F_{ratio} × TCS) + (F_{ratio} - ½)]	T_ref × [{F_{ratio} × TCS) + (F_{ratio} - ½)]

T_ref = CLKSPIREF period in ns. F_{ratio} = SPI clock division ratio

The clock divider ratio depends on divider granularity MCSPI_CH(I)CONF[CLKG]:

- MCSPI_CH(I)CONF[CLKG] = 0 : granularity is power of two.
  $F_{ratio} = 2^{MCSPI_CH(I)CONF[CLKD]}$
- MCSPI_CH(I)CONF[CLKG] = 0 : granularity is power of two.

Copyright © 2011, Texas Instruments Incorporated

F_{ratio} = MCSPI_CH(I)CNTRL[EXTCLK].MCSPI_CH(I)CONF[CLKD] + 1

Copyright © 2011, Texas Instruments Incorporated

24.3.3.9 Clock Ratio Granularity

By default the clock division ratio is defined by the register MCSPI_CH(I)CONF[CLKD] with power of two granularity leading to a clock division in range 1 to 32768, in this case the duty cycle is always 50%. With bit MCSPI_CH(I)CONF[CLKG] the clock division granularity can be changed to one clock cycle, in that case the register MCSPI_CH(I)CTRL[EXTCLK] is concatenated with MCSPI_CH(I)CONF[CLKD] to give a 12-bit width division ratio in range 1 to 4096.

When granularity is one clock cycle (MCSPI_CH(I)CONF[CLKG] set to 1), for odd value of clock ratio the clock duty cycle is kept to 50-50 using falling edge of clock reference CLKSPIREF.

Table 24-8. CLKSPIO High/Low Time Computation

Clock Ratio F_{ratio}	CLKSPIO High Time	CLKSPIO Low Time
1	T_{high}_ref	T_{low}_ref
Even ≥ 2	t_ref × (F_{ratio}/2)	t_ref × (F_{ratio}/2)
Odd ≥ 3	t_ref × (F_{ratio}/2)	t_ref × (F_{ratio}/2)

T_ref = CLKSPIREF period in ns. T_{high}_ref = CLKSPIREF high Time period in ns. T_{low}_ref = CLKSPIREF low Time period in ns. F_{ratio} = SPI clock division ratio

F_{ratio} = MCSPI_CH(I)CTRL[EXTCLK].MCSPI_CH(I)CONF[CLKD] + 1

For odd ratio value the duty cycle is calculated as below:

Duty_cycle = ½

Granularity examples: With a clock source frequency of 48 MHz:

Table 24-9. Clock Granularity Examples

MCSPI_CH (I)CTRL	MCSPI_CH (I)CONF	MCSPI_CH (I)CONF		MCSPI_CH (I)CONF	MCSPI_CH (I)CONF	Thigh (ns)	Tlow (ns)	Tperiod (ns)	Duty Cycle	Fout (MHz)

24.3.3.10 FIFO Buffer Management (Optional USEFIFO = 1)

The McSPI controller has a built-in FFNBYTE bytes buffer in order to unload DMA or interrupt handler and improve data throughput. The use of this buffer is optional and depends on a generic parameter USEFIFO. The FIFO is enabled when it is set to 1. Allowed FIFO depth up to 64 bytes is supported and is defined by generic parameter FFNBYTE. When the FIFO is not enabled, writes to registers MCSPI_XFERLEVEL, MCSPI_CH(I)CONF[FFER] and MCSPI_CH(I)CONF[FFEW] have no functional effect, nevertheless read back is allowed to check written value.

This buffer can be used by only one channel and is selected by setting MCSPI_CH(I)CONF[FFER] and/or MCSPI_CH(I)CONF[FFEW] to 1.

If several channels are selected and several FIFO enable bit fields set to 1, the controller forces the buffer to be disabled for all channels. It is the responsibility of the driver to enable the buffer for only one channel.

The buffer can be used in the modes defined below:

- Master or Slave mode.
- Transmit only, Receive only or Transmit/Receive mode.
- Single channel or turbo mode, or in normal round robin mode. In round robin mode the buffer is used by only one channel.
- All word length MCSPI_CH(I)CONF[WL] are supported.

Two levels AEL and AFL located in MCSPI_XFERLEVEL register rule the buffer management. The granularity of these levels is one byte, then it is not aligned with SPI word length. It is the responsibility of the driver to set these values as a multiple of SPI word length defined in MCSPI_CH(I)CONF[WL]. The number of byte written in the FIFO depends on word length (see Table 24-10).

Table 24-10. FIFO Writes, Word Length Relationship

	SPI Word Length WL		
	3 ≤ WL ≤ 7	**8 ≤ WL ≤ 15**	**16 ≤ WL ≤ 31**
Number of byte written in the FIFO	1 byte	2 bytes	4 byte

24.3.3.10.1 Split FIFO

The FIFO can be split into two part when module is configured in transmit/receive mode MCSPI_CH(I)CONF[TRM] is cleared to 0 and MCSPI_CH(I)CONF[FFER] and MCSPI_CH(I)CONF[FFEW] asserted. Then system can access a FFNBYTE/2 byte depth FIFO per direction.

The FIFO buffer pointers are reset when the corresponding channel is enabled or FIFO configuration changes.

24.3.3.10.2 Buffer Almost Full

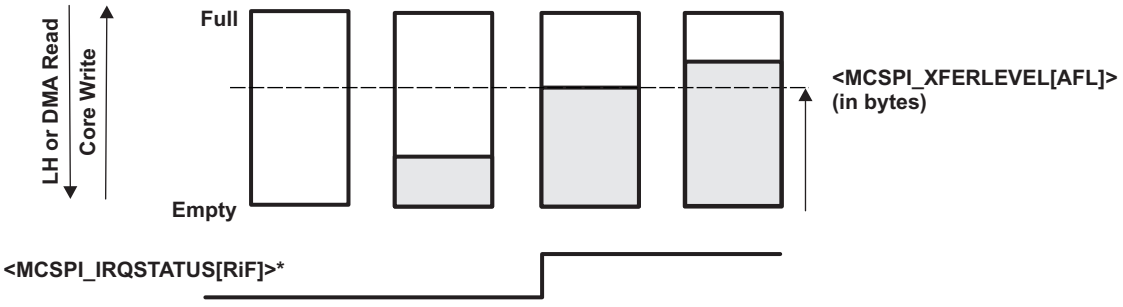
The bit field MCSPI_XFERLEVEL[AFL] is needed when the buffer is used to receive SPI word from a slave (MCSPI_CH(I)CONF[FFER] must be set to 1) and register width depends on the generic parameter FFNBYTE value. It defines the almost full buffer status.

When FIFO pointer reaches this level an interrupt or a DMA request is sent to the CPU to enable system to read AFL+1 bytes from receive register. Be careful AFL+1 must correspond to a multiple value of MCSPI_CH(I)CONF[WL].

When DMA is used, the request is de-asserted after the first receive register read.

No new request will be asserted until the system has performed the correct number of read operations from the buffer.

Figure 24-19. Buffer Almost Full Level (AFL)



*** non-DMA mode only. In DMA mode, the DMA RX request is asserted to its active level under identical conditions.**

.

NOTE: SPI_IRQSTATUS register bits are not available in DMA mode. In DMA mode, the SPIm_DMA_RX*n* request is asserted on the same conditions as the SPI_IRQSTATUS RX*n*_FULL flag.

Copyright © 2011, Texas Instruments Incorporated

24.3.3.10.3 Buffer Almost Empty

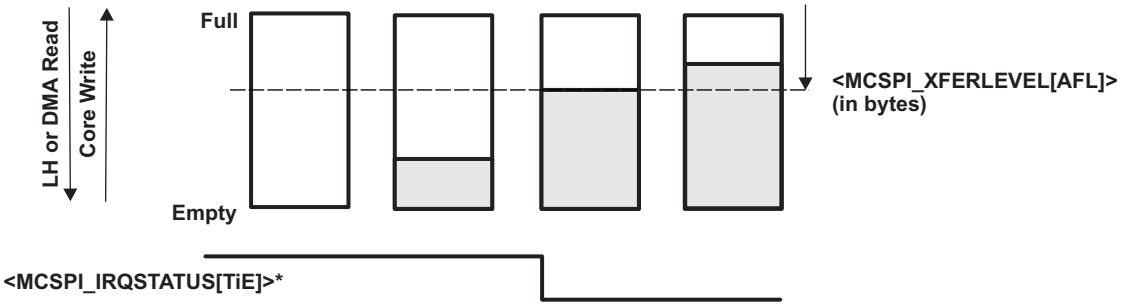
The bitfield MCSPI_XFERLEVEL[AEL] is needed when the buffer is used to transmit SPI word to a slave (MCSPI_CH(I)CONF[FFEW]must be set to 1) and register width depends on the generic parameter FFNBYTE value. It defines the almost empty buffer status.

When FIFO pointer has not reached this level an interrupt or a DMA request is sent to the CPU to enable system to write AEL+1 bytes to transmit register. Be careful AEL+1 must correspond to a multiple value of MCSPI_CH(I)CONF[WL].

When DMA is used, the request is de-asserted after the first transmit register write.

No new request will be asserted until the system has performed the correct number of write operations.

Figure 24-20. Buffer Almost Empty Level (AEL)



* non-DMA mode only. In DMA mode, the DMA TX request is asserted to its active level under identical conditions.

.

24.3.3.10.4 End of Transfer Management

When the FIFO buffer is enabled for a channel, the user should configure the MCSPI_XFERLEVEL register, the AEL and AFL levels, and, especially, the WCNT bit field to define the number of SPI word to be transferred using the FIFO. This should be done before enabling the channel.

This counter allows the controller to stop the transfer correctly after a defined number of SPI words have been transferred. If WNCT is cleared to 0, the counter is not used and the user must stop the transfer manually by disabling the channel, in this case the user doesn't know how many SPI transfers have been done. For receive transfer, software shall poll the corresponding FFE bit field and read the Receive register to empty the FIFO buffer.

When End Of Word count interrupt is generated, the user can disable the channel and poll on MCSPI_CH(I)STAT[FFE] register to know if SPI word is still there in FIFO buffer and read last words.

Copyright © 2011, Texas Instruments Incorporated

24.3.3.10.5 Multiple SPI Word Access

The CPU has the ability to perform multiple SPI word access to the receive or transmit registers within a single 32-bit OCP access by setting the bit field MCSPI_MODULCTRL[MOA] to '1' under specific conditions:

- The channel selected has the FIFO enable.
- Only FIFO sense enabled support the kind of access.
- The bit field MCSPI_MODULCTRL[MOA] is set to 1
- Only 32-bit OCP access and data width can be performed to receive or transmit registers, for other kind of access the CPU must de-assert MCSPI_MODULCTRL[MOA] bit fields.
- The Level MCSPI_XFERLEVEL[AEL] and MCSPI_XFERLEVEL[AFL] must be 32-bit aligned , it means that AEL[0] = AEL[1] = 1 or AFL[0] = AFL[1] = 1.
- If MCSPI_XFERLEVEL[WCNT] is used it must be configured according to SPI word length.
- The word length of SPI words allows to perform multiple SPI access, that means that MCSPI_CH(I)CONF[WL] < 16

Number of SPI word access depending on SPI word length:

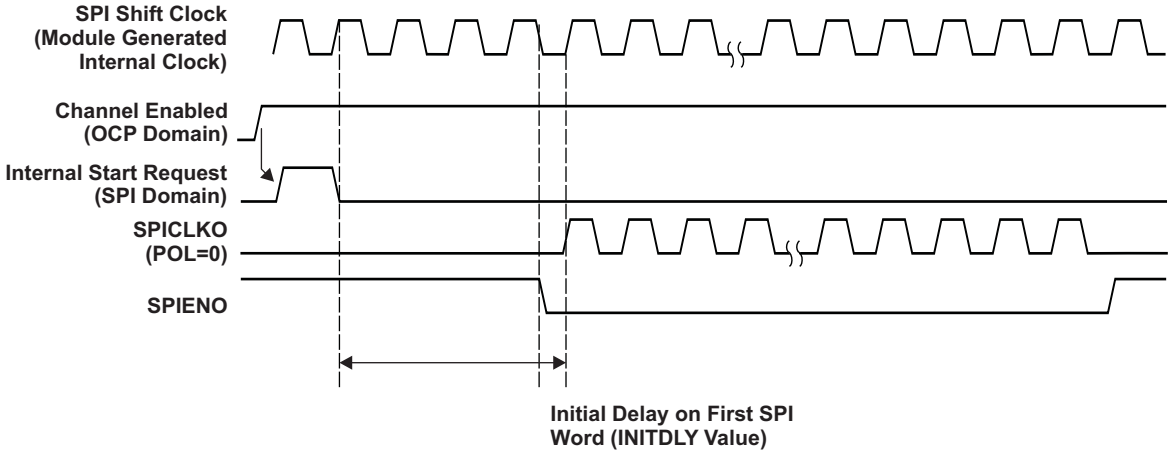
- 3 ≤ WL ≤ 7, SPI word length smaller or equal to byte length, four SPI words accessed per 32-bit OCP read/write. If word count is used (MCSPI_XFERLEVEL[WCNT]), set the bit field to WCNT[0]=WCNT[1]=0
- 8 ≤ WL ≤ 15, SPI word length greater than byte or equal to 16-bit length, two SPI words accessed per 32-bit OCP read/write. If word count is used (MCSPI_XFERLEVEL[WCNT]), set the bit field to WCNT[0]= 0.
- 16 ≤ WL multiple SPI word access not applicable.

24.3.3.11 First SPI Word Delayed

The McSpi controller has the ability to delay the first SPI word transfer to give time for system to complete some parallel processes or fill the FIFO in order to improve transfer bandwidth. This delay is applied only on first SPI word after SPI channel enabled and first write in Transmit register. It is based on output clock frequency.

This option is meaningful in master mode and single channel mode MCSPI_MODULECTRL[SINGLE] asserted.

Figure 24-21. Master Single Channel Initial Delay



Few delay values are available: No delay, 4/8/16/32 Spi cycles.

Its accuracy is half cycle in clock bypass mode and depends on clock polarity and phase.

Copyright © 2011, Texas Instruments Incorporated

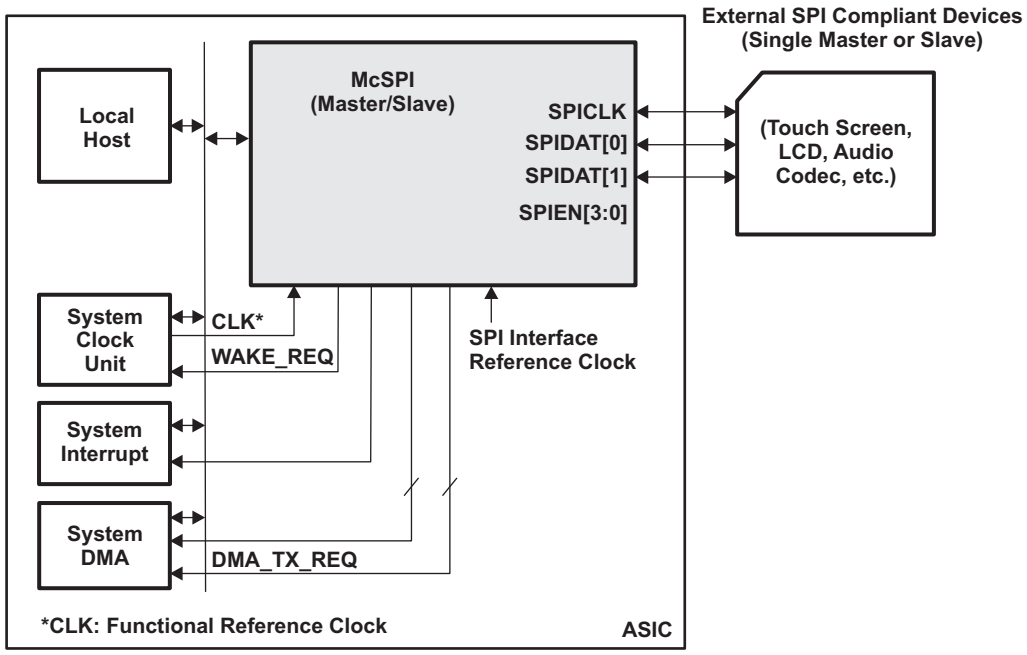
24.3.3.12 3- or 4-Pin Mode

External SPI bus interface can be configured to use a restricted set of pin using the bit field MCSPI_MODULCTRL[PIN34] and depending on targeted application:

- If MCSPI_MODULCTRL[PIN34] is cleared to 0 (default value) the controller is in 4-pin mode using the SPI pins CLKSPI, SOMI, SIMO and chip enable CS.
- If MCSPI_MODULCTRL[PIN34] is set to 1 the controller is in 3-pin mode using the SPI pins CLKSPI, SOMI and SIMO.

In 3-pin mode it is mandatory to put the controller in single channel master mode (MCSPI_MODULECTRL[SINGLE] asserted) and to connect only one SPI device on the bus.

Figure 24-22. 3-Pin Mode System Overview



In 3-pin mode all options related to chip select management are useless:

- MCSPI_CHxCONF[EPOL]
- MCSPI_CHxCONF[TCS0]
- MCSPI_CHxCONF[FORCE]

The chip select pin SPIEN is forced to ‘0’ in this mode.

Copyright © 2011, Texas Instruments Incorporated

24.3.4 Slave Mode

McSPI is in slave mode when the bit MS of the register MCSPI_MODULCTRL is set.

In slave mode, McSPI can be connected to up to 4 external SPI master devices. McSPI handles transactions with a single SPI master device at a time.

In slave mode, McSPI initiates data transfer on the data lines (SPIDAT[1;0]) when it receives an SPI clock (SPICLK) from the external SPI master device.

The controller is able to work with or without a chip select SPIEN depending on MCSPI_MODULCTRL[PIN34] bit setting. It also supports transfers without a dead cycle between two successive words.

24.3.4.1 Dedicated Resources

In slave mode, enabling a channel that is not channel 0 has no effect. Only channel 0 can be enabled. The channel 0, in slave mode has the following resources:

- Its own channel enable, programmable with the bit EN of the register MCSPI_CH0CTRL. This channel should be enabled before transmission and reception. Disabling the channel, outside data word transmission, remains under user responsibility.
- Any of the 4 ports SPIEN[3:0] can be used as a slave SPI device enable. This is programmable with the bits SPIENSLV of the register MCSPI_CH0CONF.
- Its own transmitter register MCSPI_TX on top of the common shift register. If the transmitter register is empty, the status bit TXS of the register MCSPI_CH0STAT is set. When McSPI is selected by an external master (active signal on the SPIEN port assigned to channel 0), the transmitter register content of channel0 is always loaded in shift register whether it has been updated or not. The transmitter register should be loaded before McSPI is selected by a master.
- Its own receiver register MCSPI_RX on top of the common shift register. If the receiver register is full, the status bit RXS of the register MCSPI_CH0STAT is set.

NOTE: The transmitter register and receiver registers of the other channels are not used. Read from or Write in the registers of a channel other than 0 has no effect.

- Its own communication configuration with the following parameters via the register MCSPI_CH0CONF:
  - Transmit/Receive modes, programmable with the bit TRM.
  - Interface mode (Two data pins or Single data pin) and data pins assignment, both programmable with the bits IS and DPE.
  - SPI word length, programmable with the bits WL.
  - SPIEN polarity, programmable with the bit EPOL.
  - SPICLK polarity, programmable with the bit POL.
  - SPICLK phase, programmable with the bit PHA.
  - Use a FIFO buffer or not, programmable with FFER and FFEW, depending on transfer mode TRM.

The SPICLK frequency of a transfer is controlled by the external SPI master connected to McSPI. The bits CLKD0 of the register 0CONF are not used in slave mode.

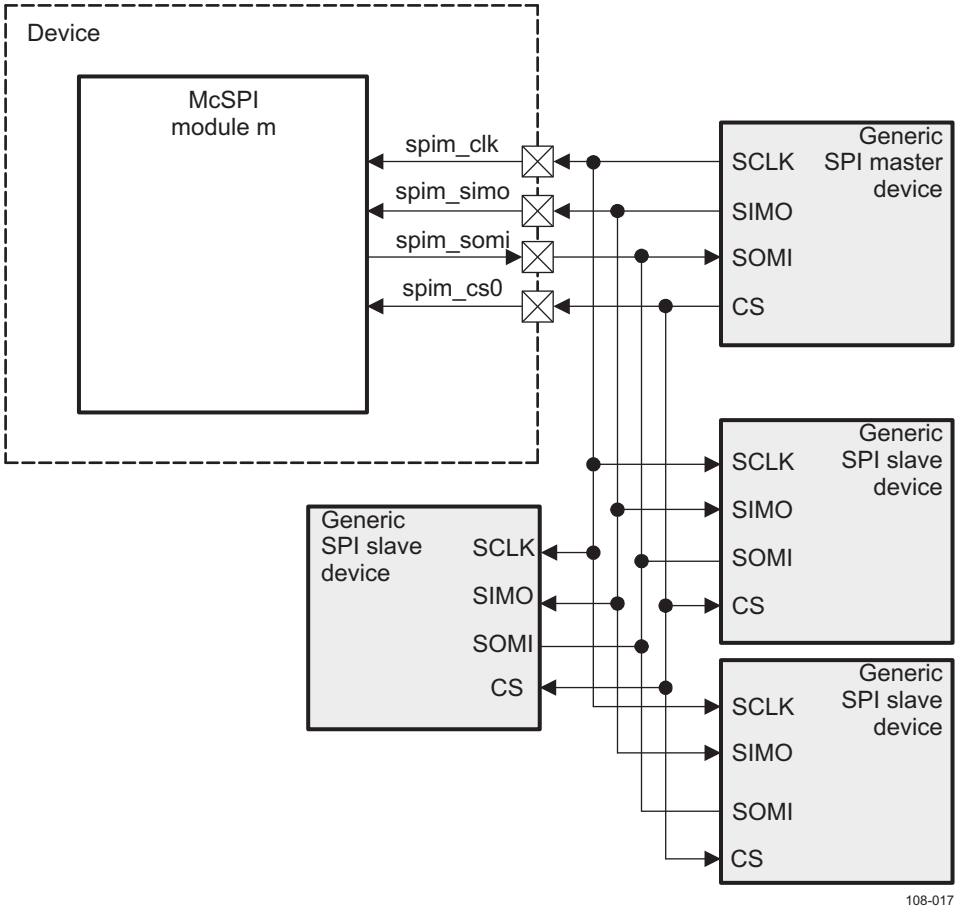
NOTE: The configuration of the channel can be loaded in the MCSPI_CH0CONF register only when the channel is disabled.

- Two DMA requests events, read and write, to synchronize read/write accesses of the DMA controller with the activity of McSPI. The DMA requests are enabled with the bits DMAR and DMAW of the register 0CONF.
- Four interrupts events.

Figure 24-23 shows an example of four slaves wired on a single master device.

Copyright © 2011, Texas Instruments Incorporated

Figure 24-23. Example of SPI Slave with One Master and Multiple Slave Devices on Channel 0



24.3.4.2 Interrupt Events in Slave Mode

The interrupt events related to the transmitter register state are TX_empty and TX_underflow. The interrupt events related to the receiver register state are RX_full and RX_overflow.

24.3.4.2.1 TX_EMPTY

The event TX_empty is activated when the channel is enabled and its transmitter register becomes empty. Enabling channel automatically raises this event. When FIFO buffer is enabled (MCSPI_CH(I)CONF[FFEW] set to 1), the TX_empty is asserted as soon as there is enough space in buffer to write a number of byte defined by MCSPI_XFERLEVEL[AEL].

Transmitter register must be load to remove source of interrupt and TX_empty interrupt status bit must be cleared for interrupt line de-assertion (if event enable as interrupt source).

When FIFO is enabled, no new TX_empty event will be asserted unless the host performs the number of writes to the transmitter register defined by MCSPI_XFERLEVEL[AEL]. It is the responsibility of the Local Host to perform the right number of writes.

Copyright © 2011, Texas Instruments Incorporated

24.3.4.2.2 TX_UNDERFLOW

The event TX_underflow is activated when channel is enabled and if the transmitter register or FIFO (if use of buffer is enabled) is empty (not updated with new data) when an external master device starts a data transfer with McSPI (transmit and receive).

When the FIFO is enabled, the data read while the underflow flag is set will not be the last word written to the FIFO.

The TX_underflow indicates an error (data loss) in slave mode.

To avoid having TX_underflow event at the beginning of a transmission, the event TX_underflow is not activated when no data has been loaded into the transmitter register since channel has been enabled.

TX_underflow interrupt status bit must be cleared for interrupt line de-assertion (if event enable as interrupt source).

24.3.4.2.3 RX_FULL

The event RX_FULL is activated when channel is enabled and receiver becomes filled (transient event). When FIFO buffer is enabled (MCSPI_CH(I)CONF[FFER] set to 1), the RX_FULL is asserted as soon as there is a number of bytes holds in buffer to read defined by MCSPI_XFERLEVEL[AFL].

Receiver register must be read to remove source of interrupt and RX_full interrupt status bit must be cleared for interrupt line de-assertion (if event enable as interrupt source).

When FIFO is enabled, no new RX_FULL event will be asserted unless the host has performed the number of reads from the receive register defined by MCSPI_XFERLEVEL[AFL]. It is the responsibility of Local Host to perform the right number of reads.

24.3.4.2.4 RX_OVERFLOW

The RX0_OVERFLOW event is activated in slave mode in either transmit-and-receive or receive-only mode, when a channel is enabled and the SPI_RX*n* register or FIFO is full when a new SPI word is received. The SPI_RX*n* register is always overwritten with the new SPI word. If the FIFO is enabled, data within the FIFO is overwritten, it must be considered as corrupted. The RX0_OVERFLOW event should not appear in slave mode using the FIFO.

The RX0_OVERFLOW indicates an error (data loss) in slave mode.

The SPI_IRQSTATUS[3] RX0_OVERFLOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

24.3.4.2.5 End of Word Count

The event end of word (EOW) count is activated when channel is enabled and configured to use the built-in FIFO. This interrupt is raised when the controller had performed the number of transfer defined in MCSPI_XFERLEVEL[WCNT] register. If the value was programmed to 0000h, the counter is not enabled and this interrupt is not generated.

The EOW count interrupt also indicates that the SPI transfer has halted on the channel using the FIFO buffer.

The EOW interrupt status bit must be cleared for interrupt line de-assertion (if event enable as interrupt source).

24.3.4.3 Slave Transmit-and-Receive Mode

The slave transmit and receive mode is programmable (TRM bit cleared to 0 in the register MCSPI_CH(I)CONF).

After the channel is enabled, transmission and reception proceeds with interrupt and DMA request events.

In slave transmit and receive mode, transmitter register should be loaded before McSPI is selected by an external SPI master device.

Copyright © 2011, Texas Instruments Incorporated

Transmitter register or FIFO (if enabled) content is always loaded into the shift register whether it has been updated or not. The event TX_underflow is activated accordingly, and does not prevent transmission.

On completion of SPI word transfer (bit EOT of the register MCSPI_CH(I)STAT is set) the received data is transferred to the channel receive register. This bit is meaningless when using the Buffer for this channel.

The built-in FIFO is available in this mode and can be configured in one data direction, transmit or receive, then the FIFO is seen as a unique FFNBYTE byte buffers. It can also be configured in both data directions, transmit and receive, then the FIFO is split into two separate FFNBYTE/2 bytes buffer with their own address space management. In this last case, the definition of AEL and AFL levels is based on FFNBYTE bytes and is under Local Host responsibility.

24.3.4.4 Slave Receive-Only Mode

The slave receive mode is programmable (MCSPI_CH(i)CONF[TRM set to 01).

In receive-only mode, the transmitter register should be loaded before McSPI is selected by an external SPI master device. Transmitter register or FIFO (if enabled) content is always loaded into the shift register whether it has been updated or not. The event TX_underflow is activated accordingly, and does not prevent transmission.

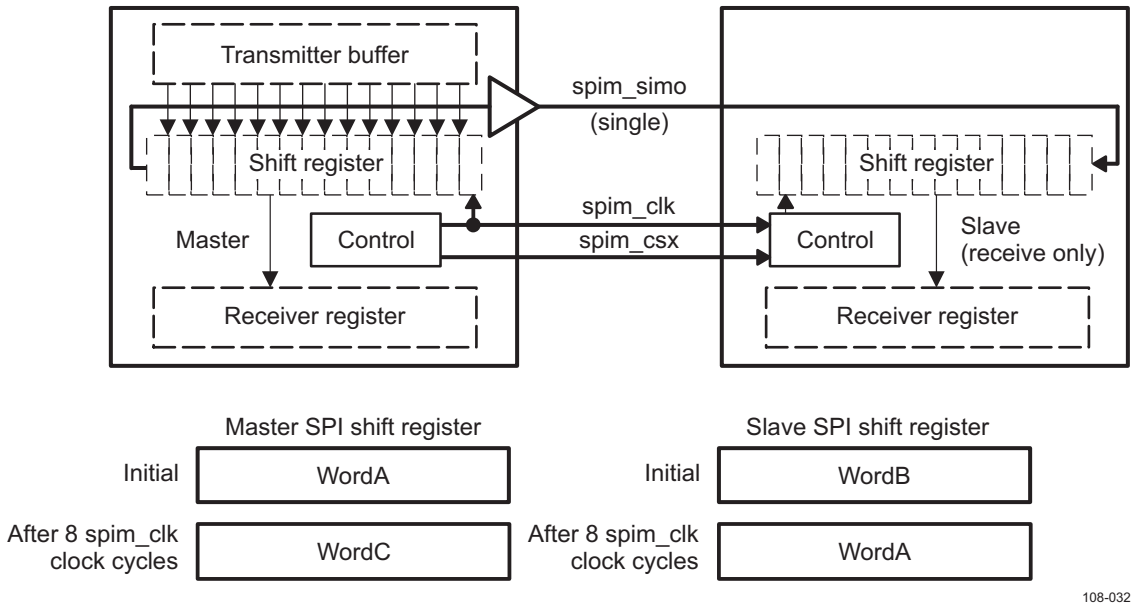
When an SPI word transfer completes (the MCSPI_CH(I)STAT[EOT] bit (with *I* = 0) is set to 1), the received data is transferred to the channel receive register.

To use McSPI as a slave receive-only device with MCSPI_CH(I)CONF[TRM]=00, the user has the responsibility to disable the TX_empty and TX_underflow interrupts and DMA write requests due to the transmitter register state.

On completion of SPI word transfer (bit EOT of the register MCSPI_CH(I)STAT is set) the received data is transferred to the channel receive register. This bit is meaningless when using the Buffer for this channel. The built-in FIFO is available in this mode and can be configured with FFER bit field in the MCSPI_CH(I)CONF register, then the FIFO is seen as a unique FFNBYTE byte buffer.

Figure 24-24 shows an example of a half-duplex system with a master device on the left and a receive-only slave device on the right. Each time one bit transfers out from the master, one bit transfers in to the slave. If WordA is 8 bits, then after eight cycles of the serial clock spim_clk, WordA transfers from the master to the slave.

Figure 24-24. SPI Half-Duplex Transmission (Receive-Only Slave)



Copyright © 2011, Texas Instruments Incorporated

24.3.4.5 Slave Transmit-Only Mode

The slave transmit-only mode is programmable (MCSPI_CH(i)CONF[TRM set to 10). This mode eliminates the need for the CPU to read the receiver register (minimizing data movement) when only transmission is meaningful.

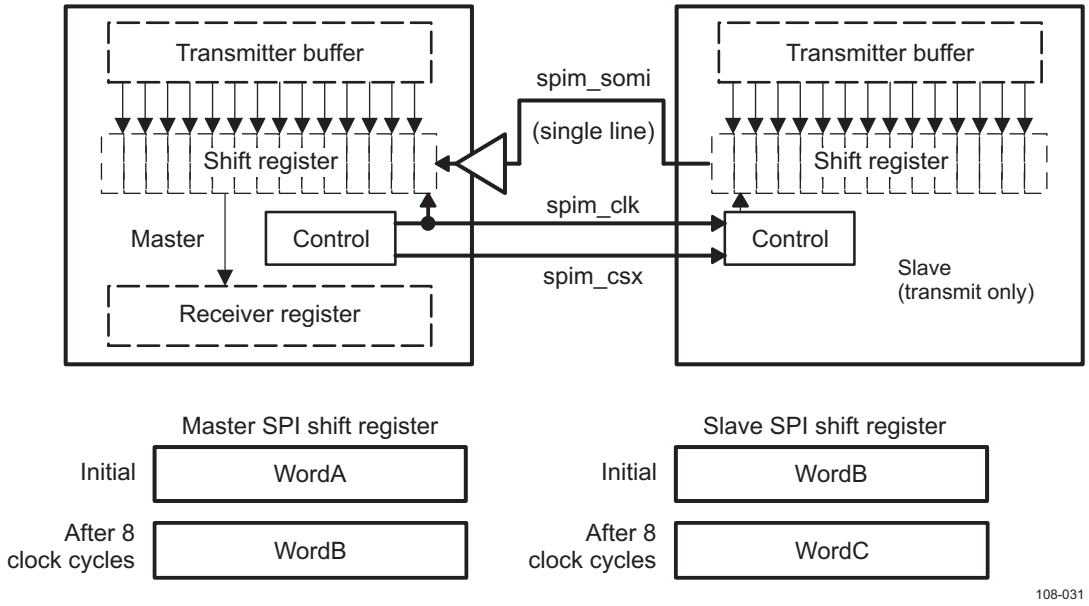
To use McSPI as a slave transmit-only device with MCSPI_CH(I)CONF[TRM]=10, the user should disable the RX_full and RX_overflow interrupts and DMA read requests due to the receiver register state.

On completion of SPI word transfer the bit EOT of the register MCSPI_CH(I)STAT is set. This bit is meaningless when using the Buffer for this channel.

The built-in FIFO is available in this mode and can be configured with FFER bit field in the MCSPI_CH(I)CONF register, then the FIFO is seen as a unique FFNBYTE bytes buffer.

Figure 24-25 shows a half-duplex system with a master device on the left and a transmit-only slave device on the right. Each time a bit transfers out from the slave device, one bit transfers in the master. If WordB is 8-bits, then after eight cycles of the serial clock spim_clk, WordB transfers from the slave to the master.

Figure 24-25. SPI Half-Duplex Transmission (Transmit-Only Slave)



24.3.5 Interrupts

According to its transmitter register state and its receiver register state each channel can issue interrupt events if they are enabled.

The interrupt events are listed in the Section 24.3.3.2 and in Section 24.3.4.2.

Each interrupt event has a status bit, in the MCSPI_IRQSTATUS register, which indicates service is required, and an interrupt enable bit, in the MCSPI_IRQENABLE register, which enables the status to generate hardware interrupt requests.

When an interrupt occurs and it is later masked (IRQENABLE), the interrupt line is not asserted again even if the interrupt source has not been serviced.

McSPI supports interrupt driven operation and polling.

Copyright © 2011, Texas Instruments Incorporated

24.3.5.1 Interrupt-Driven Operation

Alternatively, an interrupt enable bit, in the MCSPI_IRQENABLE register, can be set to enable each of the events to generate interrupt requests when the corresponding event occurs. Status bits are automatically set by hardware logic conditions.

When an event occurs (the single interrupt line is asserted), the CPU must:

- Read the MCSPI_IRQSTATUS register to identify which event occurred,
- Read the receiver register that corresponds to the event in order to remove the source of an RX_full event, or write into the transmitter register that corresponds to the event in order to remove the source of a TX_empty event. No action is needed to remove the source of the events TX_underflow and RX_overflow.
- Write a 1 into the corresponding bit of MCSPI_IRQSTATUS register to clear the interrupt status, and release the interrupt line.

The interrupt status bit should always be reset after the channel is enabled and before the event is enabled as an interrupt source.

24.3.5.2 Polling

When the interrupt capability of an event is disabled in the MCSPI_IRQENABLE register, the interrupt line is not asserted and:

- The status bits in the MCSPI_IRQSTATUS register can be polled by software to detect when the corresponding event occurs.
- Once the expected event occurs, CPU must read the receiver register that corresponds to the event in order to remove the source of an RX_full event, or write into the transmitter register that corresponds to the event in order to remove the source of a TX_empty event. No action is needed to remove the source of the events TX_underflow and RX_overflow.
- Writing a 1 into the corresponding bit of MCSPI_IRQSTATUS register clears the interrupt status and does not affect the interrupt line state.

24.3.6 DMA Requests

McSPI can be interfaced with a DMA controller. At system level, the advantage is to free the local host of the data transfers.

According to its transmitter register state, its receiver register state or FIFO level (if use of buffer for the channel) each channel can issue DMA requests if they are enabled.

The DMA requests need to be disabled in order to get TX and RX interrupts, in order to define either the end of the transfer or the transfer of the last words for the modes listed below:

- Master Transmit On
- Master normal receive only mode
- Master turbo receive only m
- Slave Transmit Only

There are two DMA request lines per channel. The management of DMA requests differ according to use of FIFO buffer or not:

24.3.6.1 FIFO Buffer Disabled

The DMA Read request line is asserted when the channel is enabled and a new data is available in the receive register of the channel. DMA Read request can be individually masked with the bit DMAR of the register MCSPI_CH(I)CONF. The DMA Read request line is de-asserted on read completion of the receive register of the channel.

The DMA Write request line is asserted when the channel is enabled and the transmitter register of the channel is empty. DMA Write request can be individually masked with the bit DMAW of the register MCSPI_CH(I)CONF. The DMA Write request line is de-asserted on load completion of the transmitter register of the channel.

Copyright © 2011, Texas Instruments Incorporated

Only one SPI word can be transmitted/received per OCP bus access to write/read the transmit or receive register.

24.3.6.2 FIFO Buffer Enabled

The DMA Read request line is asserted when the channel is enabled and a number of bytes defined in MCSPI_XFERLEVEL[AFL] bit field is hold in FIFO buffer for the receive register of the channel. DMA Read request can be individually masked with the bit DMAR of the register MCSPI_CH(I)CONF. The DMA Read request line is de-asserted on the first SPI word read completion of the receive register of the channel. No new DMA request will be asserted again as soon as user has not performed the right number of read accesses defined by MCSPI_XFERLEVEL[AFL] it is under user responsibility.

The DMA Write request line is asserted when the channel is enabled and the number of bytes hold in FIFO buffer is below the level defined by the MCSPI_XFERLEVEL[AEL] bit field. DMA Write request can be individually masked with the bit DMAW of the register MCSPI_CH(I)CONF. The DMA Write request line is de-asserted on load completion of the first SPI word in the transmitter register of the channel. No new DMA request will be asserted again as soon as user has not performed the right number of write accesses defined by MCSPI_XFERLEVEL[AEL] it is under user responsibility.

Only one SPI word can be transmitted/received per OCP bus access to write/read the transmit or receive FIFO.

24.3.6.3 DMA 256-Bit Aligned Addresses

The controller has two registers, MCSPI_DAFTX and MCSPI_DAFRX, used only with an enabled channel which manages the FIFO to be compliant the a DMA handler providing only 256-bit aligned addresses.

This features is activated when the bit field MCSPI_MODULCTRL[FDDA] is set to ‘1’ and only one enabled channel have its bit field MCSPI_CH(I)CONF[FFEW] or MCSPI_CH(I)CONF[FFER] enabled.

In this case the registers MCSPI_TX(I) and MCSPI_RX(I) are not used and data is managed through registers MCSPI_DAFTX and MCSPI_DAFRX.

24.3.7 Emulation Mode

The MReqDebug input differentiates a regular access of a processor (application access), from an emulator access.

Application access: MReqDebug = 0

In functional mode, the consequences of a read of a receiver register MCSPI_RX(i) are the following:

- The source of an RXi_Full event in the MCSPI_IRQSTATUS register is removed, if it was enabled in the MCSPI_IRQENABLE register.
- The RXiS status bit in the MCSPI_IRQSTATUS register is cleared.
- In master mode, depending on the round robin arbitration, and the transmitter register state, the channel may access to the shift register for transmission/reception.

Emulator access: MReqDebug = 1

In emulation mode, McSPI behavior is the same as in functional mode but a read of a receiver register MCSPI_RX(i) is not intrusive:

- MCSPI_RX(i) is still considered as not read. When the FIFO buffer is enabled, pointers are not updated.
- The source of an RXi_Full event in the MCSPI_IRQSTATUS register is not removed. The RXiS status bit in the MCSPI_CH(i)STAT register is held steady.

In emulation mode, as in functional mode, based on the ongoing data transfers, the status bits of the MCSPI_CH(i)STAT register may be optionally updated, the interrupt and DMA request lines may be optionally asserted.

Copyright © 2011, Texas Instruments Incorporated

24.3.8 Power Saving Management

Independently of the module operational modes (Transmit and/or Receive), two modes of operations are defined from a power management perspective: normal and idle modes.

The two modes are temporally fully exclusive.

24.3.8.1 Normal Mode

Both the OCP clock and SPI clock (CLKSPIREF) provided to McSPI must be active for both master and slave modes. The auto-gating of the module OCP clock and SPI clock occurs when the following conditions are met:

- The bit AutoIdle of the register MCSPI_SYSCONFIG is set.
- In master mode, there is no data to transmit or receive in all channels.
- In slave mode, the SPI is not selected by the external SPI master device and no OCP accesses.

Autogating of the module OCP clock and SPI clock stops when the following conditions are met:

- In master mode, an OCP access occurs.
- In slave mode, an OCP access occurs or McSPI is selected by an external SPI master device.

24.3.8.2 Idle Mode

The OCP clock and SPI clock provided to McSPI may be switched off on system power manager request and switched back on module request.

McSPI is compliant with the power management handshaking protocol: idle request from the system power manager, idle acknowledgement from McSPI.

The idle acknowledgement in response to an idle request from the system power manager varies according to a programmable mode in the MCSPI_SYSCONFIG register: No idle mode, force idle mode, and smart idle mode.

- When programmed for no idle mode (the bit SIdleMode of the register MCSPI_SYSCONFIG is set to “01”), the module ignores the system power manager request, and behaves normally, as if the request was not asserted.
- When programmed for smart idle mode (the bit SIdleMode of the register MCSPI_SYSCONFIG is set to “10”), the module acknowledges the system power manager request according to its internal state.
- When programmed for force idle mode (the bit SIdleMode of the register MCSPI_SYSCONFIG is set to “00”), the module acknowledges the system power manager request unconditionally.

The OCP clock will be optionally switched off, during the smart idle mode period, if the bit ClockActivity of the register MCSPI_SYSCONFIG is set.

The SPI clock will be optionally switched off, during the smart idle mode period, if the second bit ClockActivity of the register MCSPI_SYSCONFIG is set.

McSPI assumes that both clocks may be switched off whatever the value set in the field ClockActivity of the register MCSPI_SYSCONFIG.

24.3.8.2.1 Transitions from Normal Mode to Smart-Idle Mode

The module detects an idle request when the synchronous signal IdleReq is asserted.

When IdleReq is asserted, any access to the module will generate an error as long as the OCP clock is alive.

When configured as a slave device, McSPI responds to the idle request by asserting the SIdleAck signal (idle acknowledgement) only after completion of the current transfer (SPIEN slave selection signal deasserted by the external master) and if interrupt or DMA request lines are not asserted.

As a master device, McSPI responds to the idle request by asserting the SIdleAck signal (idle acknowledgement) only after completion of all the channel data transfers and if interrupt or DMA request lines are not asserted.

Copyright © 2011, Texas Instruments Incorporated

As long as SIdleAck is not asserted, if an event occurs, the module can still generate an interrupt or a DMA request after IdleReq assertion. In this case, the module ignores the idle request and SIdleAck will not get asserted: The system power manager will abort the power mode transition procedure. It is then the responsibility of the system to de-assert IdleReq before attempting to access the module.

When SIdleAck is asserted, the module does not assert any new interrupt or DMA request.

24.3.8.2.2 Transition From Smart-Idle Mode to Normal mode

McSPI detects the end of the idle period when the idle request signal (IdleReq) is deasserted.

Upon IdleReq de-assertion, the module switches back to normal mode and de-asserts SIdleAck signal. The module is fully operational.

24.3.8.2.3 Force-Idle Mode

Force-idle mode is enabled as follows:

- The bit SIdleMode of the register MCSPI_SYSCONFIG is cleared to “00” (Force Idle).

  The force idle mode is an idle mode where McSPI responds unconditionally to the idle request by asserting the SIdleAck signal and by deasserting unconditionally the interrupt and DMA request lines if asserted.

  The transition from normal mode to idle mode does not affect the interrupt event bits of the MCSPI_IRQSTATUS register.

  In force-idle mode, the module is supposed to be disabled at that time, so the interrupt and DMA request lines are likely deasserted. OCP clock and SPI clock provided to McSPI can be switched off.

  An idle request during an SPI data transfer can lead to an unexpected and unpredictable result, and is under software responsibility.

  Any access to the module in force idle mode will generate an error as long as the OCP clock is alive and IdleReq is asserted.

The module exits the force idle mode when:

- The idle request signal (IdleReq) is de-asserted.

  Upon IdleReq de-assertion, the module switches back to normal mode and de-asserts SIdleAck signal. The module is fully operational. The interrupt and DMA request lines are optionally asserted a clock cycle later.

24.3.9 System Test Mode

McSPI is in system test mode (SYSTEST) when the bit System_Test of the register MCSPI_MODULCTRL is set.

The SYSTEST mode is used to check in a very simple manner the correctness of the system interconnect either internally to interrupt handler, or power manager, or externally to SPI I/Os.

I/O verification can be performed in SYSTEST mode by toggling the outputs and capturing the logic state of the inputs. (See MCSPI_SYST register definition in Section 24.5.6)

24.3.10 Reset

24.3.10.1 Internal Reset Monitoring

The module is reset by the hardware when an active-low reset signal, synchronous to the OCP interface clock is asserted on the input pin RESETN.

This hardware reset signal has a global reset action on the module. All configuration registers and all state machines are reset, in all clock domains.

Additionally, the module can be reset by software through the bit SoftReset of the register MCSPI_SYSCONFIG. This bit has exactly the same action on the module logic as the hardware RESETN signal. The register MCSPI_SYSCONFIG is not sensitive to software reset. The SoftReset control bit is active high. The bit is automatically reset to 0 by the hardware.

Copyright © 2011, Texas Instruments Incorporated

A global ResetDone status bit is provided in the status register MCSPI_SYSSTATUS. This bit is set to 1 when all the different clock domains resets (OCP domain and SPI domains) have been released (logical AND).

The global ResetDone status bit can be monitored by the software to check if the module is ready-to-use following a reset (either hardware or software).

The clock CLKSPIREF must be provided to the module, in order to allow the ResetDone status bit to be set.

When used in slave mode, the clock CLKSPIREF is needed only during the reset phase. The clock CLKSPIREF can be switched off after the ResetDone status is set.

24.3.10.2 Reset Values of Registers

The reset values of registers and signals are described in Section 24.5.

24.3.11 Access to Data Registers

This section details the supported data accesses (read or write) from/to the data receiver registers MCSPI_RX(i) and data transmitter registers MCSPI_TX(i).

Supported access:

McSPI supports only one SPI word per register (receiver or transmitter) and does not support successive 8-bit or 16-bit accesses for a single SPI word.

The SPI word received is always right justified on LSbit of the 32bit register MCSPI_RX(i), and the SPI word to transmit is always right justified on LSbit of the 32bit register MCSPI_TX(i).

The upper bits, above SPI word length, are ignored and the content of the data registers is not reset between the SPI data transfers.

The coherence between the number of bits of the SPI Word, the number of bits of the access and the enabled byte remains under the user's responsibility. Only aligned accesses are supported.

In Master mode, data should not be written in the transmit register when the channel is disbaled.

24.3.12 Programming Aid

24.3.12.1 Module Initialization

- Hard or soft reset.
- Read MCSPI_SYSSTATUS.
- Check if reset is done.
- Module configuration: (a) Write into MCSPI_MODULCTRL (b) Write into MCSPI_SYSCONFIG.
- Before the ResetDone bit is set, the clocks CLK and CLKSPIREF must be provided to the module.
- To avoid hazardous behavior, it is advised to reset the module before changing from MASTER mode to SLAVE mode or from SLAVE mode to MASTER mode.

24.3.12.2 Common Transfer Sequence

McSPI module allows the transfer of one or several words, according to different modes:

- MASTER, MASTER Turbo, SLAVE
- TRANSMIT - RECEIVE, TRANSMIT ONLY, RECEIVE ONLY
- Write and Read requests: Interrupts, DMA
- SPIEN lines assertion/deassertion: automatic, manual

For all these flows, the host process contains the main process and the interrupt routines. The interrupt routines are called on the interrupt signals or by an internal call if the module is used in polling mode.

In multi-channel master mode, the flows of different channels can be run simultaneously.

Copyright © 2011, Texas Instruments Incorporated

24.3.12.3 Main Program

- Interrupt Initialization: (a) Reset status bits in MCSPI_IRQSTATUS (b) Enable interrupts in MCSPI_IRQENA.
- Channel Configuration: Write MCSPI_CH(i)CONF.
- Start the channel: Write 0000 0001h in MCSPI_CH(i)CTRL.
- First write request: TX empty - Generate DMA write event/ polling TX empty flag by CPU to write First transmit word into MCSPI_TX(i).
- End of transfer: Stop the channel by writing 0000 0000h in MCSPI_CH(i)CTRL

The end of transfer depends on the transfer mode.

In multi-channel master mode, be careful not to overwrite the bits of other channels when initializing MCSPI_IRQSTATUS and MCSPI_IRQENABLE.

24.3.13 Interrupt and DMA Events

McSPI has two DMA requests (Rx and Tx) per channel. It also has one interrupt line for all the interrupt requests.

24.5.1 McSPI Revision Register (MCSPI_REVISION)

The McSPI system configuration register (MCSPI_REVISION) allows control of various parameters of the module interface. It is not sensitive to software reset. The MCSPI_REVISION register is shown in Figure 24-26 and described in Table 24-12.

Figure 24-26. McSPI Revision Register (MCSPI_REVISION)

24.5.3 McSPI System Status Register (MCSPI_SYSSTATUS)

The McSPI system status register (MCSPI_SYSSTATUS) provides status information about the module excluding the interrupt status information. The MCSPI_SYSSTATUS is shown in Figure 24-28 and described in Table 24-14.

Figure 24-28. McSPI System Status Register (MCSPI_SYSSTATUS)

24.5.4 McSPI Interrupt Status Register (MCSPI_IRQSTATUS)

The McSPI interrupt status register (MCSPI_IRQSTATUS) regroups all the status of the module internal events that can generate an interrupt. The MCSPI_IRQSTATUS is shown in Figure 24-29 and described in Table 24-15.

NOTE: In SYSTEST mode, the bits of this register have no meaning and always read 0.

Figure 24-29. McSPI Interrupt Status Register (MCSPI_IRQSTATUS)

LEGEND: R/W = Read/Write; *-n* = value after reset

Table 24-15. McSPI Interrupt Status Register (MCSPI_IRQSTATUS) Field Descriptions

Bit	Field	Value	Description
31-18	Reserved	0	Reads returns 0
17	EOW		End of word (EOW) count event when a channel is enabled using the FIFO buffer and the channel has sent the number of McSPI words defined by the MCSPI_XFERLEVEL[WCNT].
		Write 0	Event status bit is unchanged.
		Read 0	Event false.
		Write 1	Event status bit is reset.
		Read 1	Event is pending.
16	Reserved	0	Reserved
15	Reserved	0	Reads returns 0
14	RX3_FULL		Receiver register is full or almost full. Only when Channel 3 is enabled. This bit indicate FIFO almost full status when built-in FIFO is used for receive register (MCSPI_CH3CONF[FFE3R] is set).
		Write 0	Event status bit is unchanged.
		Read 0	Event false.
		Write 1	Event status bit is reset.
		Read 1	Event is pending.
13	TX3_UNDERFLOW		Transmitter register underflow. Only when Channel 3 is enabled. The transmitter register is empty (not updated by Host or DMA with new data) before its time slot assignment. Exception: No TX_underflow event when no data has been loaded into the transmitter register since channel has been enabled.
		Write 0	Event status bit is unchanged.
		Read 0	Event false.
		Write 1	Event status bit is reset.
		Read 1	Event is pending.

Table 24-15. McSPI Interrupt Status Register (MCSPI_IRQSTATUS) Field Descriptions (continued)

Bit	Field	Value	Description
12	TX3_EMPTY		Transmitter register is empty or almost empty. This bit indicate FIFO almost full status when built-in FIFO is used for transmit register (MCSPI_CH3CONF[FFE3W] is set).
			Note: Enabling the channel automatically raises this event.
		Write 0	Event status bit is unchanged.
		Read 0	Event false.
		Write 1	Event status bit is reset.
		Read 1	Event is pending.
11	Reserved	0	Reads returns 0
10	RX2_FULL		Receiver register full or almost full. Channel 2 This bit indicate FIFO almost full status when built-in FIFO is used for receive register (MCSPI_CH3CONF[FFE2R] is set).
		Write 0	Event status bit is unchanged.
		Read 0	Event false.
		Write 1	Event status bit is reset.
		Read 1	Event is pending.
9	TX2_UNDERFLOW		Transmitter register underflow. Channel 2
		Write 0	Event status bit is unchanged.
		Read 0	Event false.
		Write 1	Event status bit is reset.
		Read 1	Event is pending.
8	TX2_EMPTY		Transmitter register empty or almost empty. Channel 2. This bit indicate FIFO almost full status when built-in FIFO is used for transmit register (MCSPI_CH3CONF[FFE2W] is set).
		Write 0	Event status bit is unchanged.
		Read 0	Event false.
		Write 1	Event status bit is reset.
		Read 1	Event is pending.
7	Reserved	0	Reads returns 0
6	RX1_FULL		Receiver register full or almost full. Channel 1. This bit indicate FIFO almost full status when built-in FIFO is use for receive register (MCSPI_CH3CONF[FFE1R] is set).
		Write 0	Event status bit is unchanged.
		Read 0	Event false.
		Write 1	Event status bit is reset.
		Read 1	Event is pending.
5	TX1_UNDERFLOW		Transmitter register underflow. Channel 1.
		Write 0	Event status bit is unchanged.
		Read 0	Event false.
		Write 1	Event status bit is reset.
		Read 1	Event is pending.
4	TX1_EMPTY		Transmitter register empty or almost empty. Channel 1. This bit indicate FIFO almost full status when built-in FIFO is use for transmit register (MCSPI_CH3CONF[FFE1W] is set).
		Write 0	Event status bit is unchanged.
		Read 0	Event false.
		Write 1	Event status bit is reset.
		Read 1	Event is pending.
3	RX0_OVERFLOW		Receiver register overflow (slave mode only). Channel 0.
		Write 0	Event status bit is unchanged.
		Read 0	Event false.
		Write 1	Event status bit is reset.
		Read 1	Event is pending.

24.5.6 McSPI System Register (MCSPI_SYST)

This McSPI system register (MCSPI_SYST) is used to configure the system interconnect either internally to the peripheral bus or externally to the device I/O pads, when the module is configured in the system test (SYSTEST) mode. The MCSPI_SYST is shown in Figure 24-31 and described in Table 24-17.

Figure 24-31. McSPI System Register (MCSPI_SYST)

LEGEND: R/W = Read/Write; *-n* = value after reset

Table 24-17. McSPI System Register (MCSPI_SYST) Field Descriptions

Bit	Field	Value	Description
31-12	Reserved	0	Reads returns 0
11	SSB		Set status bit. This bit must be cleared prior attempting to clear a status bit of the MCSPI_ IRQSTATUS register.
		0	No action. Writing 0 does not clear already set status bits.
			This bit must be cleared prior attempting to clear a status bit of the <MCSPI_IRQSTATUS> register.
		1	Writing 1 sets to 1 all status bits contained in the MCSPI_IRQSTATUS register.
			Writing 1 into this bit sets to 1 all status bits contained in the <MCSPI_IRQSTATUS> register.
10	SPIENDIR		Sets the direction of the SPIEN[3:0] lines and SPICLK line.
		0	Output (as in master mode).
		1	Input (as in slave mode).
9	SPIDATDIR1		Sets the direction of the SPIDAT[1].
		0	Output
		1	Input
8	SPIDATDIR0		Sets the direction of the SPIDAT[0].
		0	Output
		1	Input
7	Reserved	0	Reserved
6	SPICLK		SPICLK line (signal data value)
			If MCSPI_SYST[SPIENDIR] = 1 (input mode direction), this bit returns the value on the CLKSPI line (high or low), and a write into this bit has no effect.
			If MCSPI_SYST[SPIENDIR] = 0 (output mode direction), the CLKSPI line is driven high or low according to the value written into this register.
5	SPIDAT_1		SPIDAT[1] line (signal data value)
			If MCSPI_SYST[SPIDATDIR1] = 0 (output mode direction), the SPIDAT[1] line is driven high or low according to the value written into this register.
			If MCSPI_SYST[SPIDATDIR1] = 1 (input mode direction), this bit returns the value on the SPIDAT[1] line (high or low), and a write into this bit has no effect.
4	SPIDAT_0		SPIDAT[0] line (signal data value)
			If MCSPI_SYST[SPIDATDIR0] = 0 (output mode direction), the SPIDAT[0] line is driven high or low according to the value written into this register.
			If MCSPI_SYST[SPIDATDIR0] = 1 (input mode direction), this bit returns the value on the SPIDAT[0] line (high or low), and a write into this bit has no effect.

Table 24-17. McSPI System Register (MCSPI_SYST) Field Descriptions (continued)

Bit	Field	Value	Description
3	SPIEN_3		SPIEN[3] line (signal data value) If MCSPI_SYST[SPIENDIR] = 0 (output mode direction), the SPIENT[3] line is driven high or low according to the value written into this register. If MCSPI_SYST[SPIENDIR] = 1 (input mode direction), this bit returns the value on the SPIEN[3] line (high or low), and a write into this bit has no effect.
2	SPIEN_2		SPIEN[2] line (signal data value) If MCSPI_SYST[SPIENDIR] = 0 (output mode direction), the SPIENT[2] line is driven high or low according to the value written into this register. If MCSPI_SYST[SPIENDIR] = 1 (input mode direction), this bit returns the value on the SPIEN[2] line (high or low), and a write into this bit has no effect.
1	SPIEN_1		SPIEN[1] line (signal data value) If MCSPI_SYST[SPIENDIR] = 0 (output mode direction), the SPIENT[1] line is driven high or low according to the value written into this register. If MCSPI_SYST[SPIENDIR] = 1 (input mode direction), this bit returns the value on the SPIEN[1] line (high or low), and a write into this bit has no effect.
0	SPIEN_0		SPIEN[0] line (signal data value) If MCSPI_SYST[SPIENDIR] = 0 (output mode direction), the SPIENT[0] line is driven high or low according to the value written into this register. If MCSPI_SYST[SPIENDIR] = 1 (input mode direction), this bit returns the value on the SPIEN[0] line (high or low), and a write into this bit has no effect.

24.5.7 McSPI Module Control Register (MCSPI_MODULCTRL)

This McSPI module control register (MCSPI_MODULCTRL) is used to configure the serial port interface. The MCSPI_MODULCTRL is shown in Figure 24-32 and described in Table 24-18.

Figure 24-32. McSPI Module Control Register (MCSPI_MODULCTRL)

31						16
Reserved						
R/W-0						

15					9	8
Reserved						FDAA
R/W-0						R/W-0

7	6	4	3	2	1	0
MOA	INITDLY		SYSTEM_TEST	MS	PIN34	SINGLE
R/W-0	R/W-0		R/W-0	R/W-0	R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 24-18. McSPI Module Control Register(MCSPI_MODULCTRL) Field Descriptions

Bit	Field	Value	Description
31-9	Reserved	0	
8	FDAA		FIFO DMA Address 256-bit aligned. This register is used when a FIFO is managed by the module and DMA connected to the controller provides only 256 bit aligned address. If this bit is set the enabled channel which uses the FIFO has its datas managed through MCSPI_DAFTX and MCSPI_DAFRX registers instead of MCSPI_TX(i) and MCSPI_RX(i) registers.
		0	FIFO data managed by MCSPI_TX(i) and MCSPI_RX(i) registers.
		1	FIFO data managed by MCSPI_DAFTX and MCSPI_DAFRX registers.
7	MOA		Multiple word ocp access. This register can only be used when a channel is enabled using a FIFO. It allows the system to perform multiple SPI word access for a single 32-bit OCP word access. This is possible for WL < 16.
		0	Multiple word access disabled
		1	Multiple word access enabled with FIFO
6-4	INITDLY		Initial SPI delay for first transfer. This register is an option only available in SINGLE master mode, The controller waits for a delay to transmit the first SPI word after channel enabled and corresponding TX register filled. This Delay is based on SPI output frequency clock, No clock output provided to the boundary and chip select is not active in 4 pin mode within this period.
		0	No delay for first SPI transfer
		1h	The controller wait 4 SPI bus clock
		2h	The controller wait 8 SPI bus clock
		3h	The controller wait 16 SPI bus clock
		4h	The controller wait 32 SPI bus clock
		5h-Fh	Reserved
3	SYSTEM_TEST		Enables the system test mode
		0	Functional mode
		1	System test mode (SYSTEST)
2	MS		Master/ Slave
		0	Master - The module generates the SPICLK and SPIEN[3:0]
		1	Slave - The module receives the SPICLK and SPIEN[3:0]
1	PIN34		Pin mode selection. This register is used to configure the SPI pin mode, in master or slave mode. If asserted the controller only use SIMO,SOMI and SPICLK clock pin for SPI transfers.
		0	SPIEN is used as a chip select.
		1	SPIEN is not used.
			In this mode all related option to chip select have no meaning.

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 24-19. McSPI Channel *(i)* Configuration Register (MCSPI_CH(i)CONF) Field Descriptions

Bit	Field	Value	Description
31-30	Reserved	0	Read returns 0
29	CLKG		Clock divider granularity. This register defines the granularity of channel clock divider: power of two or one clock cycle granularity.
			When this bit is set the register MCSPI_CHCTRL[EXTCLK] must be configured to reach a maximum of 4096 clock divider ratio. Then The clock divider ratio is a concatenation of MCSPI_CHCONF[CLKD] and MCSPI_CHCTRL[EXTCLK] values.
		0	Clock granularity of power of 2
		1	1 clock cycle granularity
28	FFER		FIFO enabled for receive. Only one channel can have this bit set.
		0	The buffer is not used to receive data.
		1	The buffer is used to receive data.
27	FFEW		FIFO enabled for transmit. Only one channel can have this bit set.
		0	The buffer is not used to transmit data.
		1	The buffer is used to transmit data.
26-25	TCS		Chip select time control. This 2-bits field defines the number of interface clock cycles between CS toggling and first or last edge of SPI clock.
		0	0.5 clock cycles
		1h	1.5 clock cycles
		2h	2.5 clock cycles
		3h	3.5 clock cycles
24	SBPOL		Start bit polarity.
		0	Start bit polarity is held to 0 during SPI transfer.
		1	Start bit polarity is held to 1 during SPI transfer.
23	SBE		Start bit enable for SPI transfer.
		0	Default SPI transfer length as specified by WL bit field.
		1	Start bit D/CX added before SPI transfer. Polarity is defined by MCSPI_CH(i)CONF[SBPOL].

Copyright © 2011, Texas Instruments Incorporated

Table 24-19. McSPI Channel *(i)* Configuration Register (MCSPI_CH(i)CONF) Field Descriptions (continued)

Bit	Field	Value	Description
22-21	SPIENSLV		Channel 0 only and slave mode only: SPI slave select signal detection. Reserved bits (read returns 0) for other cases.
		0	Detection enabled only on SPIEN[0]
		1h	Detection enabled only on SPIEN[1]
		2h	Detection enabled only on SPIEN[2]
		3h	Detection enabled only on SPIEN[3]
20	FORCE		Manual SPIEN assertion to keep SPIEN active between SPI words. (single channel master mode only)
		0	Writing 0 into this bit drives the SPIEN line when MCSPI_CHCONF(i)[EPOL]=0, and drives it high when MCSPI_CHCONF(i)[EPOL]=1.
		1	Writing 1 into this bit drives the SPIEN line when MCSPI_CHCONF(i)[EPOL]=0, and drives it low when MCSPI_CHCONF(i)[EPOL]=1
19	TURBO		Turbo mode.
		0	Turbo is deactivated (recommended for single SPI word transfer).
		1	Turbo is activated to maximize the throughput for multi-SPI word transfers.
18	IS		Input select
		0	Data line 0 (SPIDAT[0]) selected for reception.
		1	Data line 1 (SPIDAT[1]) selected for reception.
17	DPE1		Transmission enable for data line 1 (SPIDATAGZEN[1])
		0	Data line 1 (SPIDAT[1]) selected for transmission
		1	No transmission on data line 1 (SPIDAT[1])
16	DPE0		Transmission enable for data line 0 (SPIDATAGZEN[0])
		0	Data line 0 (SPIDAT[0]) selected for transmission
		1	No transmission on data line 0 (SPIDAT[0])
15	DMAR		DMA read request. The DMA read request line is asserted when the channel is enabled and new data is available in the receive register of the channel. The DMA read request line is deasserted on read completion of the receive register of the channel.
		0	DMA read request is disabled.
		1	DMA read request is enabled.
14	DMAW		DMA write request. The DMA write request line is asserted when the channel is enabled and the MCSPI_TX*n* register of the channel is empty. The DMA write request line is deasserted on load completion of the MCSPI_TX*n* register of the channel.
		0	DMA write request is disabled.
		1	DMA write request is enabled.
13-12	TRM		Transmit/receive modes.
		0	Transmit and receive mode
		1h	Receive-only mode
		2h	Transmit-only mode
		3h	Reserved

Table 24-19. McSPI Channel *(i)* Configuration Register (MCSPI_CH(i)CONF) Field Descriptions (continued)

Bit	Field	Value	Description
5-2	CLKD		Frequency divider for SPICLK. (only when the module is a Master SPI device). A programmable clock divider divides the SPI reference clock (CLKSPIREF) with a 4-bit value, and results in a new clock SPICLK available to shift-in and shift-out data. By default the clock divider ratio has a power of two granularity when MCSPI_CHCONF[CLKG] is cleared, Otherwise this register is the 4 LSB bit of a 12-bit register concatenated with clock divider extension MCSPI_CHCTRL[EXTCLK] register.
			The value description below defines the clock ratio when MCSPI_CHCONF[CLKG] is cleared to 0.
		0	Divide by 1.
		1h	2
		2h	4
		3h	8
		4h	16

24.5.9 McSPI Channel (*i*) Status Register (MCSPI_CH(i)STAT)

The McSPI channel *i* status register register (MCSPI_CH(i)STAT) provides status information about the McSPI channel *i* FIFO transmit buffer register (MCSPI_TX*n*) and the McSPI channel *i* FIFO receive buffer register (MCSPI_RX*n*) of channel *i*. The (MCSPI_CH(i)STAT) is shown in Figure 24-34 and described in Table 24-21.

Table 24-21. McSPI Channel *(i)* Status Register (MCSPI_CH(i)STAT) Field Descriptions

Bit	Field	Value	Description
31-7	Reserved	0	Read returns 0
6	RXFFF		Channel *i* FIFO receive buffer full status.
		0	FIFO receive buffer is not full.
		1	FIFO receive buffer is full.
5	RXFFE		Channel *i* FIFO receive buffer empty status.
		0	FIFO receive buffer is not empty.
		1	FIFO receive buffer is empty.
4	TXFFF		Channel *i* FIFO transmit buffer full status.
		0	FIFO transmit buffer is not full.
		1	FIFO transmit buffer is full.
3	TXFFE		Channel *i* FIFO transmit buffer empty status.
		0	FIFO transmit buffer is not empty.
		1	FIFO transmit buffer is empty.
2	EOT		Channel *i* end-of-transfer status. The definitions of beginning and end of transfer vary with master versus slave and the transfer format (transmit/receive mode, turbo mode).
		0	This flag is automatically cleared when the shift register is loaded with the data from the transmitter register (beginning of transfer).
		1	This flag is automatically set to one at the end of an SPI transfer.
1	TXS		Channel *i* transmitter register status. The bit is cleared when the host writes the most significant byte of the SPI word in the MCSPI_TX(i) register. The bit is set when enabling the channel *i* , and also when the SPI word is transferred from the MCSPI_TX(i) register to the shift register.
		0	Register is full.
		1	Register is empty.
0	RXS		Channel *i* receiver register status. The bit is cleared when enabling the channel *i*, and also when the host reads the most significant byte of the received SPI word from the MCSPI_RX(i) register. The bit is set when the received SPI word is transferred from the shift register to the MCSPI_RX(i) register.
		0	Register is empty.
		1	Register is full.

24.5.14 McSPI DMA Address Aligned FIFO Transmitter Register (MCSPI_DAFTX)

The McSPI DMA address aligned FIFO transmitter register (MCSPI_DAFTX) contains the SPI words to transmit on the serial link when FIFO is used and the DMA address is aligned on 256 bit. This register is an image of one of the MCSPI_TX(i) registers corresponding to the channel which have its FIFO enabled. The MCSPI_DAFTX register is shown in Figure 24-39 and described in Table 24-26.

NOTE: See Chapter Access to data registers for the list of supported accesses.

The SPI words are transferred with MSB first.

Figure 24-39. McSPI DMA Address Aligned FIFO Transmitter Register (MCSPI_DAFTX)

General-Purpose Input/Output

This chapter describes the GPIO of the device.

Topic **Page**

25.1 Introduction **4506**
25.2 Integration **4507**
25.3 Functional Description **4510**
25.4 GPIO Registers **4517**

Copyright © 2011, Texas Instruments Incorporated

25.1 Introduction

25.1.1 Purpose of the Peripheral

The general-purpose interface combines four general-purpose input/output (GPIO) modules. Each GPIO module provides 32 dedicated general-purpose pins with input and output capabilities; thus, the general-purpose interface supports up to 128 (4 × 32) pins. These pins can be configured for the following applications:

- Data input (capture)/output (drive)
- Keyboard interface with a debounce cell
- Interrupt generation in active mode upon the detection of external events. Detected events are processed by two parallel independent interrupt-generation submodules to support biprocessor operations.

25.1.2 GPIO Features

Each GPIO module is made up of 32 identical channels. Each channel can be configured to be used in the following applications:

- Data input/output
- Keyboard interface with a de-bouncing cell
- Synchronous interrupt generation (in active mode) upon the detection of external events (signal transition(s) and/or signal level(s))
- Wake-up request generation (in Idle mode) upon the detection of signal transition(s)

Global features of the GPIO interface are:

- Synchronous interrupt requests from each channel are processed by two identical interrupt generation sub-modules to be used independently by the ARM Subsystem
- Wake-up requests from input channels are merged together to issue one wake-up signal to the system
- Shared registers can be accessed through “Set & Clear” protocol

25.1.3 Unsupported GPIO Features

The wake-up feature of the GPIO modules is only supported on GPIO0.

Copyright © 2011, Texas Instruments Incorporated

25.2 Integration

The device instantiates four GPIO_V2 modules. Each GPIO module provides the support for 32 dedicated pins with input and output configuration capabilities. Input signals can be used to generate interruptions and wake-up signal. Two Interrupt lines are available for bi-processor operation. Pins can be dedicated to be used as a keyboard controller.

With four GPIO modules, the device allows for a maximum of 128 GPIO pins. (The exact number available varies as a function of the device configuration and pin muxing.) GPIO0 is in the Wakeup domain and may be used to wakeup the device via external sources. GPIO[1:3] are located in the peripheral domain.

Figure 25-1 and Figure 25-2 show the GPIO integration.

Figure 25-1. GPIO0 Module Integration

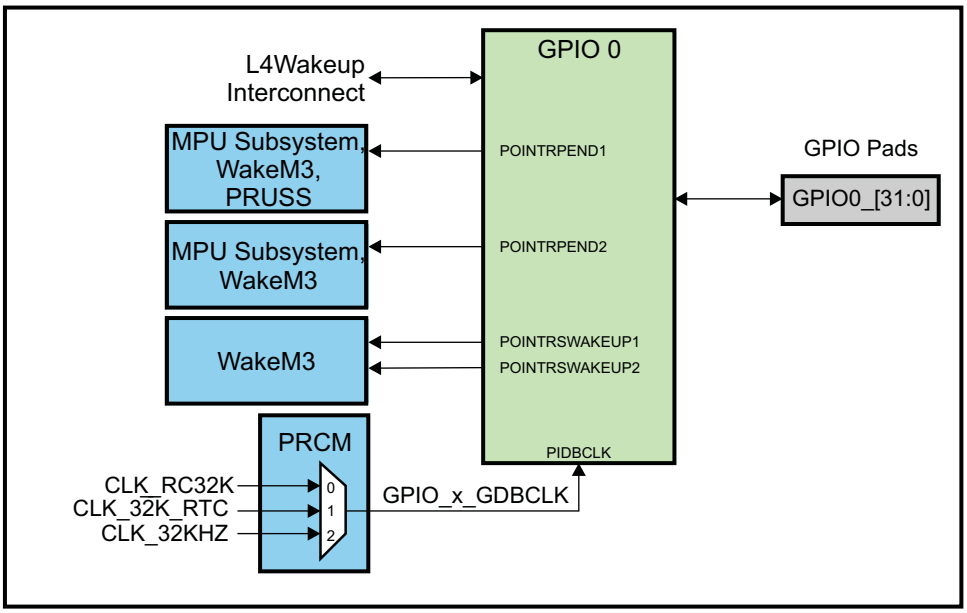

Figure 25-2. GPIO[1–3] Module Integration

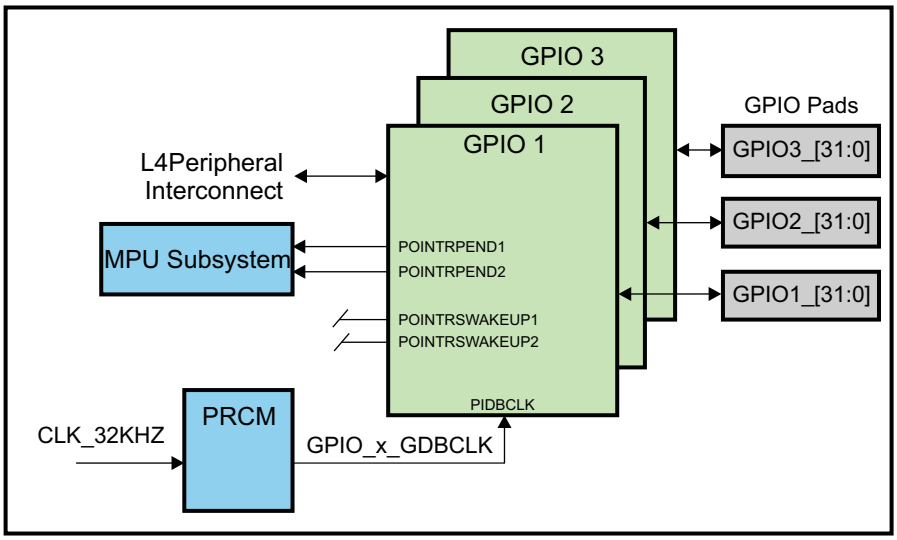

25.2.1 GPIO Connectivity Attributes

The general connectivity attributes for the GPIO modules in the device are shown in Table 25-1 and Table 25-2.

Table 25-1. GPIO0 Connectivity Attributes

Attributes	Type
Power Domain	Wakeup Domain
Clock Domain	PD_WKUP_L4_WKUP_GCLK (OCP) GPIO_0_GDBCLK (Debounce)
Reset Signals	WKUP_DOM_RST_N
Idle/Wakeup Signals	Smart Idle / Slave Wakeup
Interrupt Requests	Two Interrupts: INTRPEND1 (GPIOINT0A) to MPU subsystem, PRUSS (POINTRPEND1), and WakeM3 INTRPEND2 (GPIOINT0B) to MPU subsystem and WakeM3
DMA Requests	Interrupt Requests are redirected as DMA requests: 1 DMA request (GPIOEVT0)
Physical Address	L4 Wakeup slave port

Table 25-2. GPIO[1:3] Connectivity Attributes

Attributes	Type
Power Domain	Peripheral Domain
Clock Domain	PD_PER_L4LS_GCLK (OCP) GPIO_1_GDBCLK (GPIO1 Debounce) GPIO_2_GDBCLK (GPIO2 Debounce) GPIO_3_GDBCLK (GPIO3 Debounce)
Reset Signals	PER_DOM_RST_N
Idle/Wakeup Signals	Smart Idle
Interrupt Requests	Two Interrupts: INTRPEND1 (GPIOINTxA) to MPU subsystem INTRPEND2 (GPIOINTxB) to MPU subsystem
DMA Requests	Interrupt Requests are redirected as DMA requests: 1 DMA request only for GPIO1 (GPIOEVT1) and GPIO2 (GPIOEVT2)
Physical Address	L4 Peripheral slave port

25.2.2 GPIO Clock and Reset Management

The GPIO modules require two clocks: The de-bounce clock is used for the de-bouncing cells. The interface clock provided by the peripheral bus (L4 interface) is also the functional clock and is used through the entire GPIO module (except within the de-bouncing sub-module). It clocks the OCP interface and the internal logic. For GPIO0 the debounce clock is selected from one of three sources using the CLKSEL_GPIO0_DBCLK register in the PRCM:

- The on-chip ~32.768 KHz oscillator (CLK_RC32K)
- The PER PLL generated 32.768 KHz clock (CLK_32KHZ)
- The external 32.768 KHz oscillator/clock (CLK_32K_RTC)

Table 25-3. GPIO Clock Signals

Clock Signal	Max Freq	Reference / Source	Comments
GPIO0			
Functional / Interface clock	100 MHz	CORE_CLKOUTM4 / 2	pd_wkup_l4_wkup_gclk From PRCM
Debounce Functional clock	32.768 KHz	CLK_RC32K CLK_32KHZ (PER_CLKOUTM2 / 5859.375) CLK_32K_RTC	pd_wkup_gpio0_gdbclk From PRCM

Table 25-3. GPIO Clock Signals (continued)

Clock Signal	Max Freq	Reference / Source	Comments
Functional / Interface clock	100 MHz	CORE_CLKOUTM4 / 2	pd_per_l4ls_gclk From PRCM
Debounce Functional clock (GPIO1)	32.768 KHz	CLK_32KHZ (PER_CLKOUTM2 / 5859.375)	pd_per_gpio_1_gdbclk From PRCM
Debounce Functional clock (GPIO2)	32.768 KHz	CLK_32KHZ (PER_CLKOUTM2 / 5859.375)	pd_per_gpio_2_gdbclk From PRCM
Debounce Functional clock (GPIO3)	32.768 KHz	CLK_32KHZ (PER_CLKOUTM2 / 5859.375)	pd_per_gpio_3_gdbclk From PRCM

25.2.3 GPIO Pin List

Each GPIO module includes 32 interface I/Os. These signals are designated as shown in Table 25-4. Note that for this device, most of these signals will be multiplexed with functional signals from other interfaces.

Table 25-4. GPIO Pin List

Pin	Type	Description
GPIO0		
GPIO0_[31:0]	I/O	General Purpose Input-Output pins
GPIO1		
GPIO1_[31:0]	I/O	General Purpose Input-Output pins
GPIO2		
GPIO2_[31:0]	I/O	General Purpose Input-Output pins
GPIO3

25.3 Functional Description

This section discusses the operational details and basic functions of the GPIO peripheral.

25.3.1 Operating Modes

Four operating modes are defined for the module:

- **Active mode:** the module is running synchronously on the interface clock, interrupt can be generated according to the configuration and the external signals.
- **Idle mode:** the module is in a waiting state, interface clock can be stopped , no interrupt can be generated. Check the chip top-level functional specification for the availability of the debouncing clock while in Idle mode.
- **Inactive mode:** the module has no activity, interface clock can be stopped, no interrupt can be generated.
- **Disabled mode:** the module is not used, internal clock paths are gated, no interrupt request can be generated.

The Idle and Inactive modes are configured within the module and activated on request by the host processor through system interface sideband signals. The Disabled mode is set by software through a dedicated configuration bit. It unconditionally gates the internal clock paths not use for the system interface. All module registers are 8, 16 or 32-bit accessible through the OCP compatible interface (little endian encoding). In active mode, the event detection (level or transition) is performed in the GPIO module using the interface clock. The detection's precision is set by the frequency of this clock and the selected internal gating scheme.

25.3.2 Clocking and Reset Strategy

25.3.2.1 Clocks

GPIO module runs using two clocks:

- The debouncing clock is used for the debouncing sub-module logic (without the corresponding configuration registers). This module can sample the input line and filters the input level using a programmed delay.
- The interface clock provided by the peripheral bus (OCP compatible system interface). It is used through the entire GPIO module (except within the debouncing sub-module logic). It clocks the OCP interface and the internal logic. Clock gating features allow adapting the module power consumption to the activity.

25.3.2.2 Clocks, Gating and Active Edge Definitions

The interface clock provided by the peripheral bus (OCP compatible system interface) is used through the entire GPIO module. Two clock domains are defined: the OCP interface and the internal logic. Each clock domain can be controlled independently. Sampling operations for the data capture and for the events detection are done using the rising edge. The data loaded in the data output register (GPIO_DATAOUT) is set at the output GPIO pins synchronously with the rising edge of the interface clock.

Five clock gating features are available:

- Clock for the system interface logic can be gated when the module is not accessed, if the AUTOIDLE configuration bit in the system configuration register (GPIO_SYSCONFIG) is set. Otherwise, this logic is free running on the interface clock.
- Clock for the input data sample logic can be gated when the data in register is not accessed.
- Four clock groups are used for the logic in the synchronous events detection. Each 8 input GPIO_V2 pins group will have a separate enable signal depending on the edge/level detection register setting. If a group requires no detection, then the corresponding clock will be gated. All channels are also gated using a 'one out of N' scheme. N can take the values 1, 2, 4 or 8. The interface clock is enabled for this logic one cycle every N cycles. When N is equal to 1, there is no gating and this logic is free running on the interface clock. When N is between 2 to 8, this logic is running at the equivalent frequency of interface clock frequency divided by N.

Copyright © 2011, Texas Instruments Incorporated

- In Inactive mode, all internal clock paths are gated.
- In Disabled mode, all internal clock paths not used for the system interface are gated. All GPIO registers are accessible synchronously with the interface clock.

25.3.2.3 Sleep Mode Request and Acknowledge

Upon a Sleep mode request issued by the host processor, the GPIO module goes to the Idle mode according to the IDLEMODE field in the system configuration register (GPIO_SYSCONFIG).

- IDLEMODE = 0 (Force-Idle mode): the GPIO goes in Inactive mode independently of the internal module state and the Idle acknowledge is unconditionally sent. In Force-Idle mode, the module is in Inactive mode.
- IDLEMODE = 1h (No-Idle mode): the GPIO does not go to the Idle mode and the Idle acknowledge is never sent.
- IDLEMODE = 2h (Smart-Idle mode) or IDLEMODE = 3h (Smart-Idle mode): the GPIO module evaluates its internal capability to have the interface clock switched off. Once there is no more internal activity (the data input register completed to capture the input GPIO pins, there is no pending interrupt, all interrupt status bits are cleared, and there is no write access to GPIO_DEBOUNCINGTIME register pending to be synchronized), the Idle acknowledge is asserted and the GPIO enters Idle mode. When the system is awake, the Idle Request goes inactive, the Idle acknowledge signals are immediately de-asserted.

NOTE: Idle mode request and Idle acknowledge are system interface sideband signals. Once the GPIO acknowledges the Sleep mode request (Idle acknowledge has been sent), the interface clock can be stopped anytime.

Upon a Sleep mode request issued by the host processor, the GPIO module goes to the Idle mode only if there is no active bit in GPIO_IRQSTATUS_RAW_n registers.

25.3.2.4 Reset

The OCP hardware Reset signal has a global reset action on the GPIO. All configuration registers, all DFFs clocked with the Interface clock or Debouncing clock and all internal state machines are reset when the OCP hardware Reset is active (low level). The RESETDONE bit in the system status register (GPIO_SYSSTATUS) monitors the internal reset status: it is set when the Reset is completed on both OCP and Debouncing clock domains. The software Reset (SOFTRESET bit in the system configuration register) has the same effect as the OCP hardware Reset signal, and the RESETDONE bit in GPIO_SYSSTATUS is updated in the same condition.

25.3.3 Interrupt Features

25.3.3.1 Functional Description

In order to generate an interrupt request to a host processor upon a defined event (level or logic transition) occurring on a GPIO pin, the GPIO configuration registers have to be programmed as follows:

- Interrupts for the GPIO channel must be enabled in the GPIO_IRQSTATUS_SET_0 and/or GPIO_IRQSTATUS_SET_1 registers.
- The expected event(s) on input GPIO to trigger the interrupt request has to be selected in the GPIO_LEVELDETECT0, GPIO_LEVELDETECT1, GPIO_RISINGDETECT, and GPIO_FALLINGDETECT registers.

For instance, interrupt generation on both edges on input k is configured by setting to 1 the *k*th bit in registers GPIO_RISINGDETECT and GPIO_FALLINGDETECT along with the interrupt enabling for one or both interrupt lines (GPIO_IRQSTATUS_SET_n).

NOTE: All interrupt sources (the 32 input GPIO channels) are merged together to issue two synchronous interrupt requests 1 and 2.

Copyright © 2011, Texas Instruments Incorporated

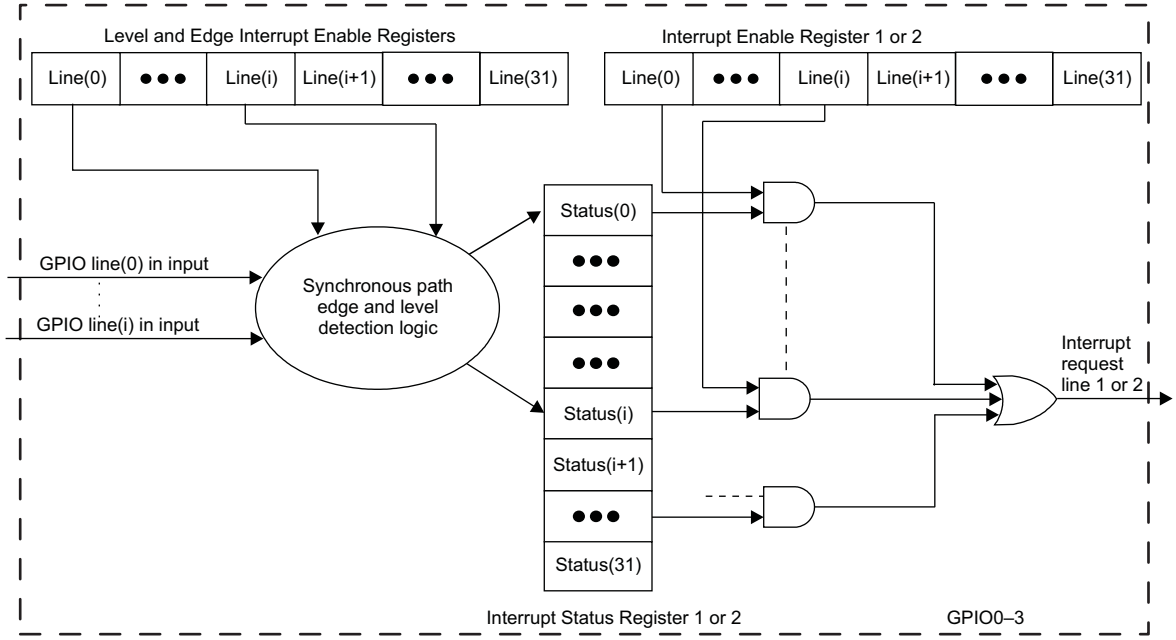
25.3.3.2 Synchronous Path: Interrupt Request Generation

In Active mode, once the GPIO configuration registers have been set to enable the interrupt generation, a synchronous path (Figure 25-3) samples the transitions and levels on the input GPIO with the internally gated interface clock. When an event matches the programmed settings, the corresponding bit in the GPIO_IRQSTATUS_RAW_n registers is set to 1 and, on the following interface clock cycle, the interrupt lines 1 and/or 2 are activated (depending on the GPIO_IRQSTATUS_SET_n registers).

Due to the sampling operation, the minimum pulse width on the input GPIO to trigger a synchronous interrupt request is two times the internally gated interface clock period (the internally gated interface clock period is equal to N times the interface clock period). This minimum pulse width has to be met before and after any expected level transition detection. Level detection requires the selected level to be stable for at least two times the internally gated interface clock period to trigger a synchronous interrupt.

As the module is synchronous, latency is minimal between the expected event occurrence and the activation of the interrupt line(s). This should not exceed 3 internally gated interface clock cycles + 2 interface clock cycles when the debouncing feature is not used. When the debouncing feature is active, the latency depends on the GPIO_DEBOUNCINGTIME register value and should be less than 3 internally gated interface clock cycles + 2 interface clock cycles + GPIO_DEBOUNCINGTIME value debouncing clock cycles + 3 debouncing clock cycles.

Figure 25-3. Interrupt Request Generation



Copyright © 2011, Texas Instruments Incorporated

25.3.3.3 Interrupt Line Release

When the host processor receives an interrupt request issued by the GPIO module, it can read the corresponding GPIO_IRQSTATUS_n register to find out which input GPIO has triggered the interrupt. After servicing the interrupt, the processor resets the status bit and releases the interrupt line by writing a 1 in the corresponding bit of the GPIO_IRQSTATUS_n register. If there is still a pending interrupt request to serve (all bits in the GPIO_IRQSTATUS_RAW_n register not masked by the GPIO_IRQSTATUS_SET_n, which are not cleared by setting the GPIO_IRQSTATUS_CLR_n), the interrupt line will be re-asserted.

25.3.4 General-Purpose Interface Basic Programming Model

25.3.4.1 Power Saving by Grouping the Edge/Level Detection

Each GPIO module implements four gated clocks used by the edge/level detection logic to save power. Each group of eight input GPIO pins generates a separate enable signal depending on the edge/level detection register setting (because the input is 32 bits, four groups of eight inputs are defined for each GPIO module). If a group requires no edge/level detection, then the corresponding clock is gated (cut off). Grouping the edge/level enable can save the power consumption of the module as described in the following example.

If any of the registers:

- GPIO_LEVELDETECT0
- GPIO_LEVELDETECT1
- GPIO_RISINGDETECT
- GPIO_FALLINGDETECT

are set to 0101 0101h, then all clocks are active (power consumption is high);

are set to 0000 00FFh, then a single clock is active.

NOTE: When the clocks are enabled by writing to the GPIO_LEVELDETECT0, GPIO_LEVELDETECT1, GPIO_RISINGDETECT, and GPIO_FALLINGDETECT registers, the detection starts after 5 clock cycles. This period is required to clean the synchronization edge/level detection pipeline.

The mechanism is independent of each clock group. If the clock has been started before a new setting is performed, the following is recommended: first, set the new detection required; second, disable the previous setting (if necessary). In this way, the corresponding clock is not gated and the detection starts immediately.

25.3.4.2 Set and Clear Instructions

The GPIO module implements the set-and-clear protocol register update for the data output and interrupt enable registers. This protocol is an alternative to the atomic test and set operations and consists of writing operations at dedicated addresses (one address for setting bit[s] and one address for clearing bit[s]). The data to write is 1 at bit position(s) to clear (or to set) and 0 at unaffected bit(s).

Registers can be accessed in two ways:

- Standard: Full register read and write operations at the primary register address
- Set and clear (recommended): Separate addresses are provided to set (and clear) bits in registers. Writing 1 at these addresses sets (or clears) the corresponding bit into the equivalent register; writing a 0 has no effect.

Therefore, for these registers, three addresses are defined for one unique physical register. Reading these addresses has the same effect and returns the register value.

Copyright © 2011, Texas Instruments Incorporated

25.3.4.2.1 Clear Instruction

25.3.4.2.1.1 Clear Interrupt Enable Registers (GPIO_IRQSTATUS_CLR_0 and GPIO_IRQSTATUS_CLR_1):

- A write operation in the clear interrupt enable1 (or enable2) register clears the corresponding bit in the interrupt enable1 (or enable2) register when the written bit is 1; a written bit at 0 has no effect.
- A read of the clear interrupt enable1 (or enable2) register returns the value of the interrupt enable1 (or enable2) register.

25.3.4.2.1.2 Clear Data Output Register (GPIO_CLEARDATAOUT):

- A write operation in the clear data output register clears the corresponding bit in the data output register when the written bit is 1; a written bit at 0 has no effect.
- A read of the clear data output register returns the value of the data output register.

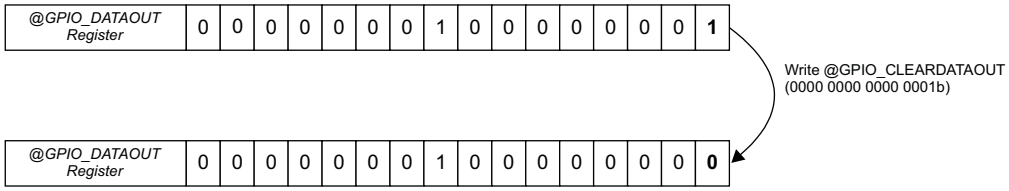
25.3.4.2.1.3 Clear Instruction Example

Assume the data output register (or one of the interrupt enable registers) contains the binary value, 0000 0001 0000 0001h, and you want to clear bit 0.

With the clear instruction feature, write 0000 0000 0000 0001h at the address of the clear data output register (or at the address of the clear interrupt enable register). After this write operation, a reading of the data output register (or the interrupt enable register) returns 0000 0001 0000 0000h; bit 0 is cleared.

NOTE: Although the general-purpose interface registers are 32-bits wide, only the 16 least-significant bits are represented in this example.

Figure 25-4. Write @ GPIO_CLEARDATAOUT Register Example



25.3.4.2.2 Set Instruction

25.3.4.2.2.1 Set Interrupt Enable Registers (GPIO_IRQSTATUS_SET_0 and GPIO_IRQSTATUS_SET_1):

- A write operation in the set interrupt enable1 (or enable2) register sets the corresponding bit in the interrupt enable1 (or enable2) register when the written bit is 1; a written bit at 0 has no effect.
- A read of the set interrupt enable1 (or enable2) register returns the value of the interrupt enable1 (or enable2) register.

25.3.4.2.2.2 Set Data Output Register (GPIO_SETDATAOUT):

- A write operation in the set data output register sets the corresponding bit in the data output register when the written bit is 1; a written bit at 0 has no effect.
- A read of the set data output register returns the value of the data output register.

Copyright © 2011, Texas Instruments Incorporated

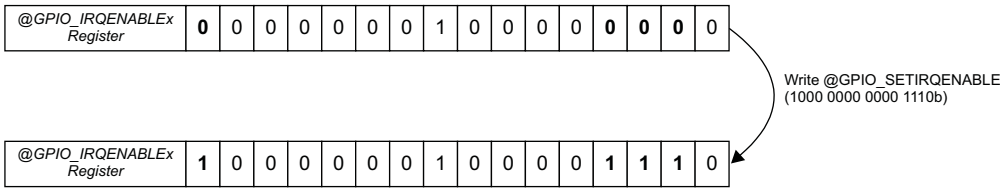
25.3.4.2.2.3 Set Instruction Example

Assume the interrupt enable1 (or enable2) register (or the data output register) contains the binary value, 0000 0001 0000 0000h, and you want to set bits 15, 3, 2, and 1.

With the set instruction feature, write 1000 0000 0000 1110h at the address of the set interrupt enable1 (or enable2) register (or at the address of the set data output register). After this write operation, a reading of the interrupt enable1 (or enable2) register (or the data output register) returns 1000 0001 0000 1110h; bits 15, 3, 2, and 1 are set.

NOTE: Although the general-purpose interface registers are 32-bits wide, only the 16 least-significant bits are represented in this example.

Figure 25-5. Write @ GPIO_SETIRQENABLEx Register Example



25.3.4.3 Data Input (Capture)/Output (Drive)

The output enable register (GPIO_OE) controls the output/input capability for each pin. At reset, all the GPIO-related pins are configured as input and output capabilities are disabled. This register is not used within the module; its only function is to carry the pads configuration.

When configured as an output (the desired bit reset in GPIO_OE), the value of the corresponding bit in the GPIO_DATAOUT register is driven on the corresponding GPIO pin. Data is written to the data output register synchronously with the interface clock. This register can be accessed with read/write operations or by using the alternate set and clear protocol register update feature. This feature lets you set or clear specific bits of this register with a single write access to the set data output register (GPIO_SETDATAOUT) or to the clear data output register (GPIO_CLEARDATAOUT) address. If the application uses a pin as an output and does not want interrupt generation from this pin, the application must properly configure the interrupt enable registers.

When configured as an input (the desired bit set to 1 in GPIO_OE), the state of the input can be read from the corresponding bit in the GPIO_DATAIN register. The input data is sampled synchronously with the interface clock and then captured in the data input register synchronously with the interface clock. When the GPIO pin levels change, they are captured into this register after two interface clock cycles (the required cycles to synchronize and to write data). If the application uses a pin as an input, the application must properly configure the interrupt enable registers to the interrupt as needed.

25.3.4.4 Debouncing Time

To enable the debounce feature for a pin, the GPIO configuration registers must be programmed as follows:

- The GPIO pin must be configured as input in the output enable register (write 1 to the corresponding bit of the GPIO_OE register).
- The debouncing time must be set in the debouncing value register (GPIO_DEBOUNCINGTIME). The GPIO_DEBOUNCINGTIME register is used to set the debouncing time for all input lines in the GPIO module. The value is global for all the ports of one GPIO module, so up to six different debouncing values are possible. The debounce cell is running with the debounce clock (32 kHz). This register represents the number of the clock cycle(s) (one cycle is 31 microseconds long) to be used.

  The following formula describes the required input stable time to be propagated to the debounced output:

  Debouncing time = (DEBOUNCETIME + 1) × 31 µs

Copyright © 2011, Texas Instruments Incorporated

Where the DEBOUNCETIME field value in the GPIO_DEBOUNCINGTIME register is from 0 to 255.

- The debouncing feature must be enabled in the debouncing enable register (write 1 to the corresponding DEBOUNCEENABLE bit in the GPIO_DEBOUNCENABLE register).

25.3.4.5 GPIO as a Keyboard Interface

The general-purpose interface can be used as a keyboard interface (Figure 25-6). You can dedicate channels based on the keyboard matrix = * c). Figure 25-6 shows row channels configured as inputs with the input debounce feature enabled. The row channels are driven high with an external pull-up. Column channels are configured as outputs and drive a low level.

When a keyboard matrix key is pressed, the corresponding row and column lines are shorted together and a low level is driven on the corresponding row channel. This generates an interrupt based on the proper configuration (see Section 25.3.3).

When the keyboard interrupt is received, the processor can disable the keyboard interrupt and scan the column channels for the key coordinates.

- The scanning sequence has as many states as column channels: For each step in the sequence, the processor drives one column channel low and the others high.
- The processor reads the values of the row channels and thus detects which keys in the column are pressed.

At the end of the scanning sequence, the processor establishes which keys are pressed. The keyboard interface can then be reconfigured in the interrupt waiting state.

25.4 GPIO Registers

All module registers are 8-, 16-, or 32-bit accessible through the L4 interconnect (little-endian encoding). Access to registers is direct; no shadow registers are implemented.

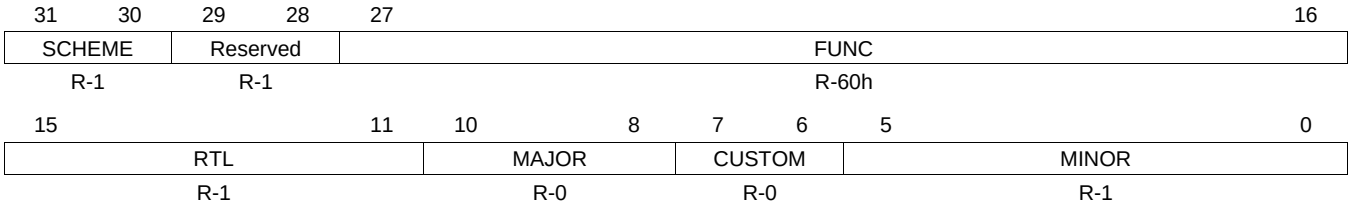
25.4.1 GPIO_REVISION Register

The GPIO revision register is a read only register containing the revision number of the GPIO module. A write to this register has no effect, the same as the reset. The GPIO_REVISION register is shown in Figure 25-7 and described in Table 25-6.

Figure 25-7. GPIO_REVISION Register



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 25-6. GPIO_REVISION Register Field Descriptions

Bit	Field	Value	Description
31-30	SCHEME	1	Used to distinguish between old Scheme and current.
29-28	Reserved	1	Reserved
27-16	FUNC	0-FFFh	Indicates a software compatible module family.
15-11	RTL	0-1Fh	RTL version
10-8	MAJOR	0-7h	Major Revision
7-6	CUSTOM	0-3h	Indicates a special version for a particular device.
5-0	MINOR	0-3Fh	Minor Revision

25.4.2 GPIO_SYSCONFIG Register

The GPIO_SYSCONFIG register controls the various parameters of the L4 interconnect. The GPIO_SYSCONFIG register is shown in Figure 25-8 and described in Table 25-7.

NOTE: When the AUTOIDLE bit is set, the GPIO_DATAIN read command has a 3 OCP cycle latency due to the data in sample gating mechanism. When the AUTOIDLE bit is not set, the GPIO_DATAIN read command has a 2 OCP cycle latency.

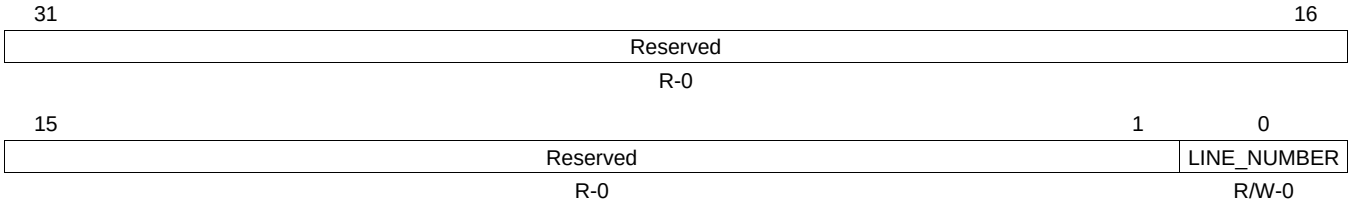
25.4.3 GPIO_EOI Register

The GPIO_EOI register provides software end of interrupt (EOI) control. The GPIO_EOI register is shown in Figure 25-9 and described in Table 25-8.

Figure 25-9. GPIO_EOI Register



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

0	LINE_NUMBER		Software End Of Interrupt (EOI) control. Write number of interrupt output.
		Write 0	EOI for interrupt output line #0
		Write 1	EOI for interrupt output line #1
		Read 0	Reads always 0 (no EOI memory)

Copyright © 2011, Texas Instruments Incorporated

25.4.4 GPIO_IRQSTATUS_RAW_n Register

The GPIO_IRQSTATUS_RAW_n register provides core status information for the interrupt handling, showing all active events (enabled and not enabled). The fields are read-write. Writing a 1 to a bit sets it to 1, that is, triggers the IRQ (mostly for debug). Writing a 0 has no effect, that is, the register value is not be modified. Only enabled, active events trigger an actual interrupt request on the IRQ output line. The GPIO_IRQSTATUS_RAW_n register is shown in Figure 25-10 and described in Table 25-9.

Figure 25-10. GPIO_IRQSTATUS_RAW_n Register

		0	No effect
		1	IRQ is triggered.

25.4.5 GPIO_IRQSTATUS_n Register

The GPIO_IRQSTATUS_n register provides core status information for the interrupt handling, showing all active events (enabled and not enabled). The fields are read-write. Writing a 1 to a bit clears the bit to 0, that is, clears the IRQ. Writing a 0 has no effect, that is, the register value is not modified. Only enabled, active events trigger an actual interrupt request on the IRQ output line. The GPIO_IRQSTATUS_n register is shown in Figure 25-11 and described in Table 25-10.

25.4.6 GPIO_IRQSTATUS_SET_n Register

All 1-bit fields in the GPIO_IRQSTATUS_SET_n register enable a specific interrupt event to trigger an interrupt request. Writing a 1 to a bit enables the interrupt field. Writing a 0 has no effect, that is, the register value is not modified. The GPIO_IRQSTATUS_SET_n register is shown in Figure 25-12 and described in Table 25-11.

25.4.8 GPIO_SYSSTATUS Register

The GPIO_SYSSTATUS register provides the reset status information about the GPIO module. It is a read-only register; a write to this register has no effect. The GPIO_SYSSTATUS register is shown in Figure 25-14 and described in Table 25-13.

Figure 25-14. GPIO_SYSSTATUS Register

25.4.9 GPIO_CTRL Register

The GPIO_CTRL register controls the clock gating functionality. The DISABLEMODULE bit controls a clock gating feature at the module level. When set, this bit forces the clock gating for all internal clock paths. Module internal activity is suspended. System interface is not affected by this bit. System interface clock gating is controlled with the AUTOIDLE bit in the system configuration register (GPIO_SYSCONFIG). This bit is to be used for power saving when the module is not used because of the multiplexing configuration selected at the chip level. This bit has precedence over all other internal configuration bits. The GPIO_CTRL register is shown in Figure 25-15 and described in Table 25-14.

		3h	Functional clock is interface clock divided by 8.
0	DISABLEMODULE		Module Disable
		0	Module is enabled, clocks are not gated.
		1	Module is disabled, clocks are gated.

25.4.10 GPIO_OE Register

The GPIO_OE register is used to enable the pins output capabilities. At reset, all the GPIO related pins are configured as input and output capabilities are disabled. This register is not used within the module, its only function is to carry the pads configuration. When the application is using a pin as an output and does not want interrupt generation from this pin, the application can/has to configure properly the Interrupt Enable registers. The GPIO_OE register is shown in Figure 25-16 and described in Table 25-15.

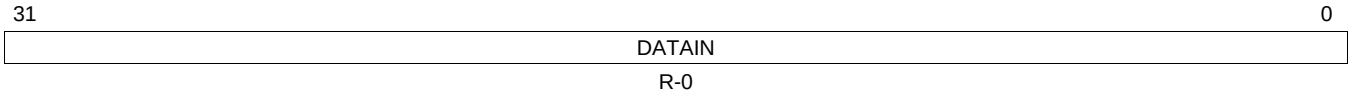
25.4.11 GPIO_DATAIN Register

The GPIO_DATAIN register is used to register the data that is read from the GPIO pins. The GPIO_DATAIN register is a read-only register. The input data is sampled synchronously with the interface clock and then captured in the GPIO_DATAIN register synchronously with the interface clock. So, after changing, GPIO pin levels are captured into this register after two interface clock cycles (the required cycles to synchronize and to write the data). The GPIO_DATAIN register is shown in Figure 25-17 and described in Table 25-16.

NOTE: When the AUTOIDLE bit in the system configuration register (GPIO_SYSCONFIG) is set, the GPIO_DATAIN read command has a 3 OCP cycle latency due to the data in sample gating mechanism. When the AUTOIDLE bit is not set, the GPIO_DATAIN read command has a 2 OCP cycle latency.

Figure 25-17. GPIO_DATAIN Register



LEGEND: R = Read only; -*n* = value after reset

Table 25-16. GPIO_DATAIN Register Field Descriptions

Bits	Field	Value	Description
31-0	DATAIN	0-FFFF FFFFh	Sampled Input Data

25.4.12 GPIO_DATAOUT Register

The GPIO_DATAOUT register is used for setting the value of the GPIO output pins. Data is written to the GPIO_DATAOUT register synchronously with the interface clock. This register can be accessed with direct read/write operations or using the alternate 'Set/Clear' feature. This feature enables to set or clear specific bits of this register with a single write access to the set data output register (GPIO_SETDATAOUT) or to the clear data output register (GPIO_CLEARDATAOUT) address. The GPIO_DATAOUT register is shown in Figure 25-18 and described in Table 25-17.

25.4.13 GPIO_LEVELDETECT0 Register

The GPIO_LEVELDETECT0 register is used to enable/disable for each input lines the low-level (0) detection to be used for the interrupt request generation. The GPIO_LEVELDETECT0 register is shown in Figure 25-19 and described in Table 25-18.

NOTE: Enabling at the same time high-level detection and low-level detection for one given pin makes a constant interrupt generator.

Figure 25-19. GPIO_LEVELDETECT0 Register

LEGEND: R/W = Read/Write; -*n* = value after reset

Table 25-18. GPIO_LEVELDETECT0 Register Field Descriptions

Bits	Field	Value	Description
31-0	LEVELDETECT0[*n*]		Low Level Interrupt Enable
		0	Disable the IRQ assertion on low-level detect.
		1	Enable the IRQ assertion on low-level detect.

25.4.14 GPIO_LEVELDETECT1 Register

The GPIO_LEVELDETECT1 register is used to enable/disable for each input lines the high-level (1) detection to be used for the interrupt request generation. The GPIO_LEVELDETECT1 register is shown in Figure 25-20 and described in Table 25-19.

NOTE: Enabling at the same time high-level detection and low-level detection for one given pin makes a constant interrupt generator.

25.4.15 GPIO_RISINGDETECT Register

The GPIO_RISINGDETECT register is used to enable/disable for each input lines the rising-edge (transition 0 to 1) detection to be used for the interrupt request generation. The GPIO_RISINGDETECT register is shown in Figure 25-21 and described in Table 25-20.

Figure 25-21. GPIO_RISINGDETECT Register

25.4.19 GPIO_CLEARDATAOUT Register

Writing a 1 to a bit in the GPIO_CLEARDATAOUT register clears to 0 the corresponding bit in the GPIO_DATAOUT register; writing a 0 has no effect. A read of the GPIO_CLEARDATAOUT register returns the value of the data output register (GPIO_DATAOUT). The GPIO_CLEARDATAOUT register is shown in Figure 25-25 and described in Table 25-24.

Figure 25-25. GPIO_CLEARDATAOUT Register

Initialization

This chapter describes the initialization of the device.

Topic **Page**

26.1 Functional Description **4532**

Copyright © 2011, Texas Instruments Incorporated

26.1 Functional Description

This chapter describes the booting functionality of the device, referred hereafter as ROM Code. The booting functionality covers the following features:

Memory Booting: Booting the device by starting code stored on permanent memories like flash-memory or memory cards. This process is usually performed after either device cold or warm reset.

Peripheral Booting: Booting the device by downloading the executable code over a communication interface like UART, USB or Ethernet. This process is intended for flashing a device.

The device always starts up in secure mode. The ROM Code takes care of early initialization. The ROM code switches the device into public mode. Hence the Public ROM Code provides run-time services for cache maintenance.

26.1.1 Architecture

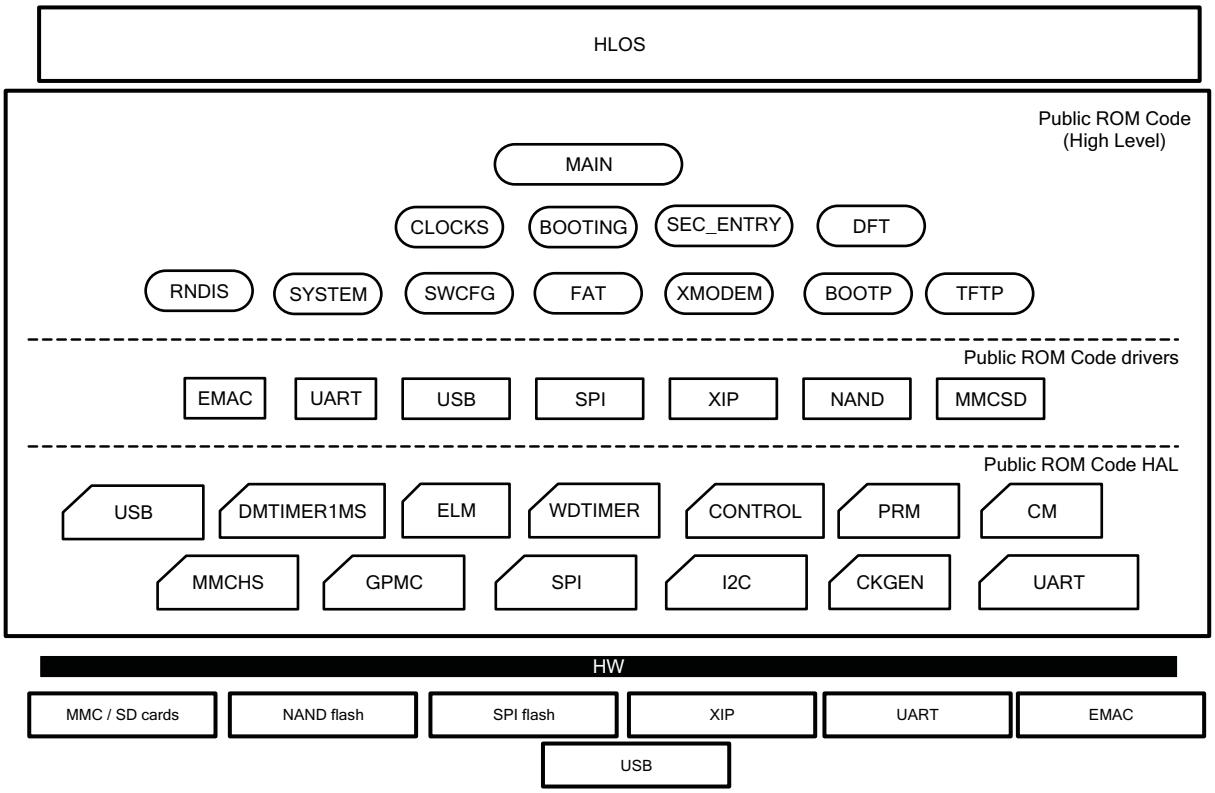
The architecture of the Public ROM Code is shown in Figure 26-1. It is split into three main layers with a top-down approach: high-level, drivers, and hardware abstraction layer (HAL). One layer communicates with a lower level layer through a unified interface.

The high level layer is in charge of the main tasks of the Public ROM Code: watchdog & clocks configuration and main booting routine.

The drivers layer implements the logical and communication protocols for any booting device in accordance with the interface specification.

Finally the HAL implements the lowest level code for interacting with the hardware infrastructure IPs. End booting devices are attached to device IO pads.

Figure 26-1. Public ROM Code Architecture



26.1.2 Functionality

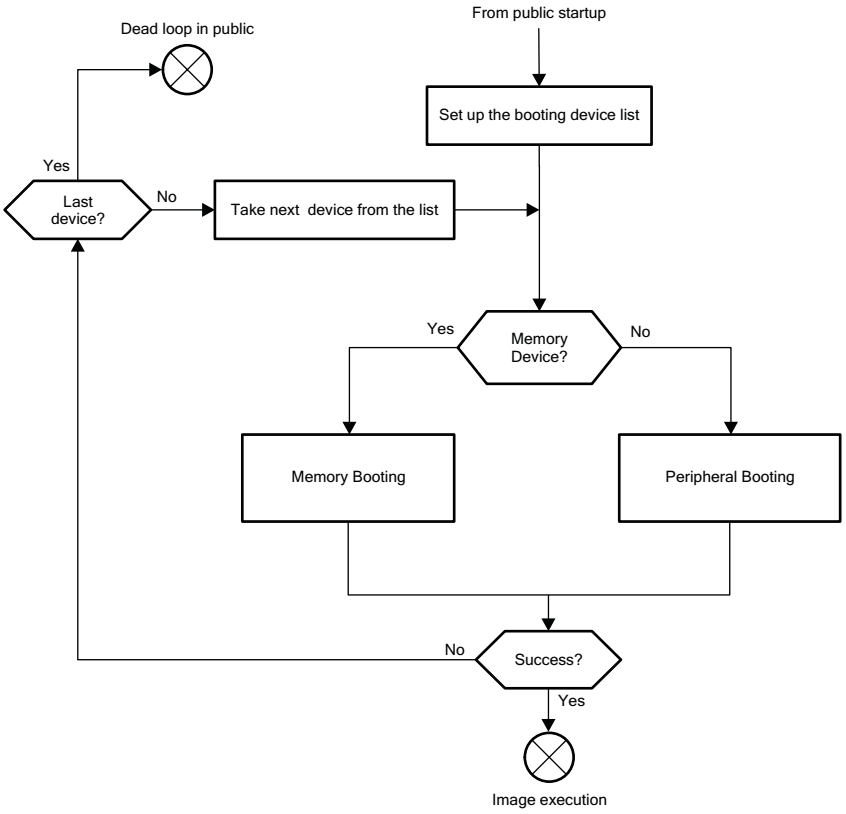
Figure 26-2 illustrates the high level flow for the Public ROM Code booting procedure. The ROM Code performs platform configuration and initialization as part of the public start-up procedure.

Copyright © 2011, Texas Instruments Incorporated

The booting device list is created based on the **SYSBOOT** pins. A booting device can be a **memory booting device** (soldered flash memory or temporarily booting device like memory card) or a **peripheral interface** connected to a host.

The main loop of the booting procedure goes through the booting device list and tries to search for an image from the currently selected booting device. This loop is exited if a valid booting image is found and successfully executed or upon watchdog expiration.

Figure 26-2. Public ROM Code Boot Procedure



26.1.3 Memory Map

26.1.3.1 Public ROM Memory Map

The on-chip ROM memory map is shown in Figure 26-3. The Public ROM Code mapping consists in the following:

- Exception vectors
- CRC
- Dead loops collection

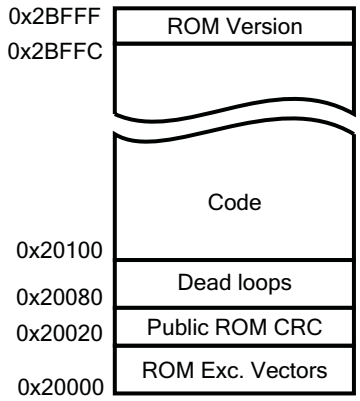
Figure 26-3. ROM Memory Map



Public ROM Exception Vectors

Table 26-1 lists the Public ROM exception vectors. The reset exception is redirected to the Public ROM Code startup. Other exceptions are redirected to their RAM handlers by loading appropriate addresses into the PC register.

Copyright © 2011, Texas Instruments Incorporated

Table 26-1. ROM Exception Vectors

Address	Exception	Content
20000h	Reset	Branch to the Public ROM Code startup
20004h	Undefined	PC = 4030CE04h
20008h	SWI	PC = 4030CE08h
2000Ch	Pre-fetch abort	PC = 4030CE0Ch
20010h	Data abort	PC = 4030CE10h
20014h	Unused	PC = 4030CE14h
20018h	IRQ	PC = 4030CE18h
2001Ch	FIQ	PC = 4030CE1Ch

Public ROM Code CRC

The Public ROM Code CRC is calculated as 32 bit CRC code (CRC-32-IEEE 802.3) for the address range 20000h–2BFFFh. The four bytes CRC code is stored at location 20020h.

Dead Loops

Built-in dead loops are used for different purposes as shown in below Table 26-2. All dead loops are branch instructions coded in ARM mode. The fixed location of these dead loops facilitates debugging and testing. The first seven dead loops are default exception handlers linked with RAM exception vectors. The dead loops might be called directly from the user code. However there exists a special function which can be called from ROM Code in order to execute a dead loop. The function is an assembly code in ARM mode which takes the dead loop address from R0 register. The main purpose of the function is to go in a dead loop until the watchdog expires and resets the device. The function is located at address 200C0h. In addition the function clears global cold reset status upon issuing the global SW reset.

Table 26-2. Dead Loops

Address	Purpose
20080h	Undefined exception default handler
20084h	SWI exception default handler
20088h	Pre-fetch abort exception default handler
2008Ch	Data abort exception default handler
20090h	Unused exception default handler
20094h	IRQ exception default handler
20098h	FIQ exception default handler
2009Ch	Validation tests PASS
200A0h	Validation tests FAIL
200A4h	Reserved
200A8h	Image not executed or returned.
200ACh	Reserved
200B0h	Reserved
200B4h	Reserved
200B8h	Reserved
200BCh	Reserved

Code

This space is used to hold code and constant data.

Public ROM Code Version

The ROM Code version consists of two decimal numbers: major and minor. It can be used to identify the ROM Code release version in a given IC (e.g., useful to identify an IC version). The ROM Code version is a 32bits hexadecimal value located at address 2BFFCh.

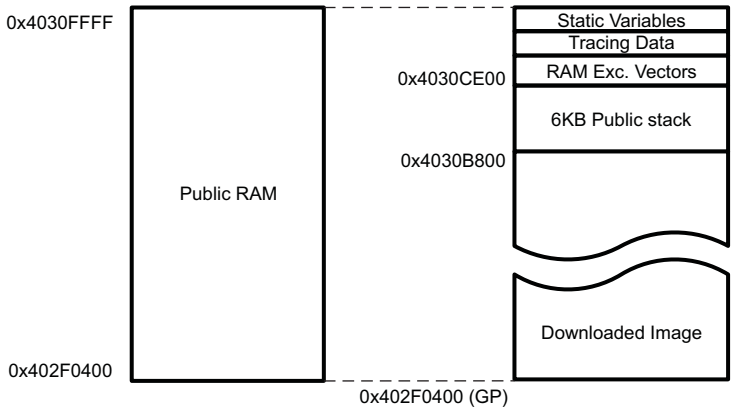
26.1.3.2 Public RAM Memory Map

The Public ROM Code makes use of the on chip RAM module connected to the L3 interconnect (further referred to as **L3 RAM**). Its usage is shown in Figure 26-4. The Public RAM memory map ranges from address 402F0400h to 4030FFFFh on a **GP Device**.

Figure 26-4. Public RAM Memory Map



Download Image

This area is used by the Public ROM Code to store the downloaded boot image. It can be up to 110KB.

Public Stack

Space reserved for stack.

RAM Exception Vectors

The RAM exception vectors enable a simple means for redirecting exceptions to custom handlers. Table 26-3 shows content of the RAM space reserved for RAM vectors. The first seven addresses are ARM instructions which load the value located in the subsequent seven addresses into the PC register. Theses instructions are executed when an exception occurs since they are called from the ROM exception vectors. Undefined, SWI, Unused and FIQ exceptions are redirected to a hardcoded dead loop. Pre-fetch abort, data abort, and IRQ exception are redirected to pre-defined ROM handlers. User code can redirect any exception to a custom handler either by writing its address to the appropriate location from 4030CE24h to 4030CE3Ch or by overriding the branch (load into PC) instruction between addresses from 4030CE04h to 4030CE1Ch.

Table 26-3. RAM Exception Vectors

Address	Exception	Content
4030CE00h	Reserved	Reserved
4030CE04h	Undefined	PC = [4030CE24h]
4030CE08h	SWI	PC = [4030CE28h]
4030CE0Ch	Pre-fetch abort	PC = [4030CE2Ch]
4030CE10h	Data abort	PC = [4030CE30h]
4030CE14h	Unused	PC = [4030CE34h]
4030CE18h	IRQ	PC = [4030CE38h]
4030CE1Ch	FIQ	PC = [4030CE3Ch]
4030CE20h	Reserved	20090h
4030CE24h	Undefined	20080h
4030CE28h	SWI	20084h

Copyright © 2011, Texas Instruments Incorporated

Table 26-3. RAM Exception Vectors (continued)

Address	Exception	Content
4030CE2Ch	Pre-fetch abort	Address of default pre-fetch abort handler(1)
4030CE30h	Data abort	Address of default data abort handler(1)
4030CE34h	Unused	20090h
4030CE38h	IRQ	Address of default IRQ handler
4030CE3Ch	FIQ	20098h

(1) The default handlers for pre-fetch and data abort are performing reads from CP15 debug registers to retrieve the reason of the abort:
- In case of pre-fetch abort: the IFAR register is read from CP15 and stored into R0. The IFSR register is read and stored into the R1 register. Then the ROM Code jumps to the pre-fetch abort dead loop (20088h).
- In case of data abort: the DFAR register is read from CP15 and stored into R0. The DFSR register is read and stored into the R1 register. Then the ROM Code jumps to the data abort dead loop (2008Ch).

Tracing Data

This area contains trace vectors reflecting the execution path of the public boot. Section 26.1.12 describes the usage of the different trace vectors and lists all the possible trace codes.

Table 26-4. Tracing Data

Address	Size[bytes]	Description
4030CE40h	4	Current tracing vector, word 1
4030CE44h	4	Current tracing vector, word 2
4030CE48h	4	Current tracing vector, word 3
4030CE4Ch	4	Current copy of the PRM_RSTST register (reset reasons)
4030CE50h	4	Cold reset run tracing vector, word 1
4030CE54h	4	Cold reset run tracing vector, word 2
4030CE58h	4	Cold reset run tracing vector, word 3
4030CE5Ch	4	Reserved
4030CE60h	4	Reserved
4030CE64h	4	Reserved

Static Variables

This area contains the ROM Code static variables used during boot time.

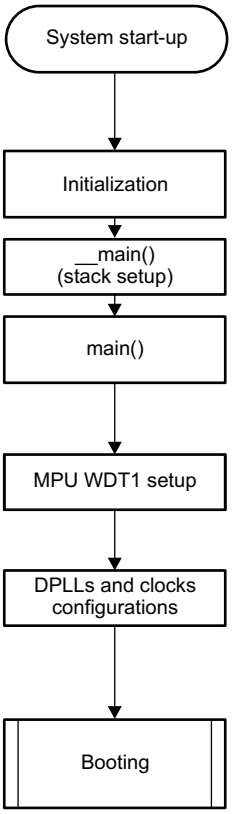
26.1.4 Start-up and Configuration

26.1.4.1 ROM Code Start-up

The Public ROM Code is physically located at the address 20000h.

Copyright © 2011, Texas Instruments Incorporated

Figure 26-5. ROM Code Startup Sequence



Upon system startup, the CPU performs the public-side initialization and stack setup (compiler auto generated C- initialization or “scatter loading”). Then it configures the watchdog timer 1 (set to three minutes), performs system clocks configuration. Finally it jumps to the booting routine.

26.1.4.2 CPU State at Public Startup

The CPU **L1 instruction cache** and **branch prediction** mechanisms are not activated as part of the public boot process. The public vector base address is configured to the reset vector of Public ROM Code (20000h). MMU is left switched off during the public boot (hence L1 data cache off).

26.1.4.3 Clocking Configuration

The device supports the following frequencies based on SYSBOOT[15:14]

Table 26-5. Crystal Frequencies Supported

SYSBOOT[15:14]	Crystal Frequency
00b	19.2 MHz
01b	24 MHz
10b	25 MHz
11b	26 MHz

The ROM Code configures the clocks and DPLLs which are necessary for ROM Code execution:

- L3 ADPLLS locked to provide 200MHz clocks for peripheral blocks.
- DDR DPLL locked to provide 400MHz.
- MPU ADPLLS is locked to provide 500 MHz for the A8.
- PER ADPLLLJ is locked to provide 960MHz and 192MHz for peripheral blocks.

Copyright © 2011, Texas Instruments Incorporated

Table 26-6 summarizes the ROM Code default settings for clocks. This default configuration enables all the ROM Code functionalities with minimized needs on power during boot.

Table 26-6. ROM Code Default Clock Settings

Clock	Frequency [MHz]	Source
L3F_CLK	200	CORE_CLKOUTM4
SPI_CLK	48	PER_CLKOUTM2
MMC_CLK	96	PER_CLKOUTM2
UART_CLK	48	PER_CLKOUTM2
I2C_CLK	48	PER_CLKOUTM2
MPU_CLK	500	MPU_PLL
USB_PHY_CLK	960 MHz	PER_CLKDCOLDO

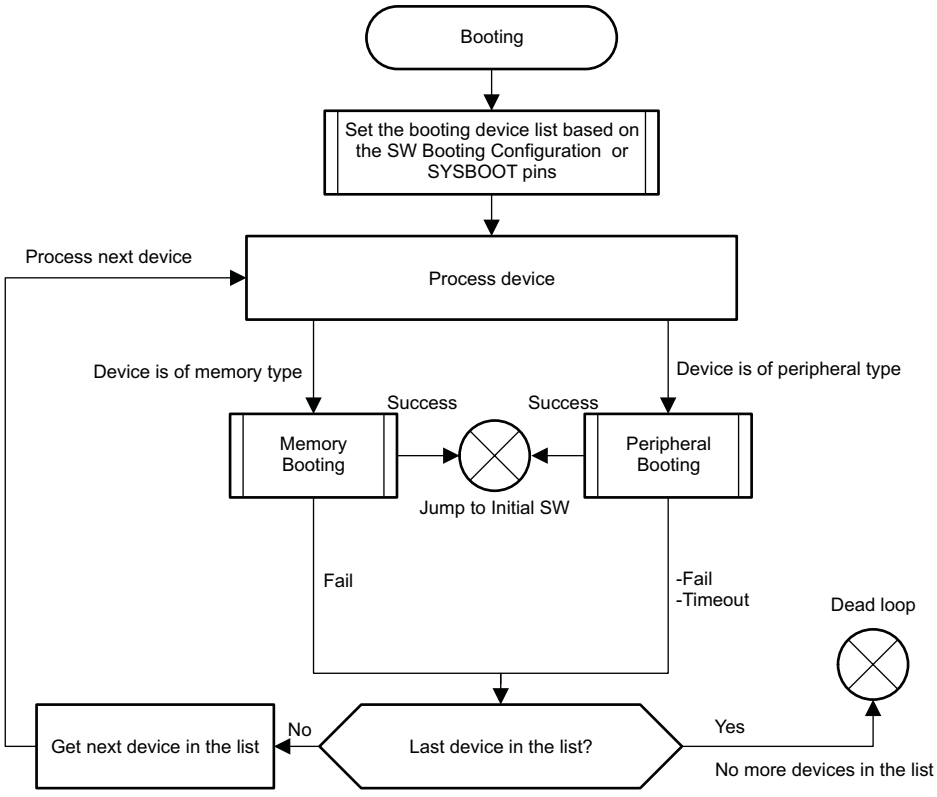
The DPLLs and PRCM clock dividers are configured with the ROM Code default values after cold or warm reset in order to give the same working conditions to the Public ROM Code sequence.

26.1.5 Booting

26.1.5.1 Overview

Figure 26-6 shows the booting procedure. First a **booting device list** is created. The list consists of all devices which will be searched for a booting image. The list is filled in based on the **SYSBOOT**.

Figure 26-6. ROM Code Booting Procedure



Once the booting device list is set up, the booting routine examines the devices enumerated in the list sequentially and either executes the memory booting or peripheral booting procedure depending on the booting device type. The memory booting procedure is executed when the booting device type is one of NOR, NAND, MMC or SPI-EEPROM. The peripheral booting is executed when the booting device type is Ethernet, USB or UART.

Copyright © 2011, Texas Instruments Incorporated

The memory booting procedure reads data from a memory type device. If a valid booting image is found and successfully read from the external memory device, the code begins to execute.

The peripheral booting procedure downloads data from a host (commonly a PC) to the device device by means of Ethernet, USB or UART links. The ROM Code uses a host-slave logical protocol for synchronization. Upon successful UART, USB or Ethernet connection the host sends the image binary contents. The peripheral booting procedure is described in detail in Section 26.1.8.

If the memory or peripheral booting fails for all devices enumerated in the device list then the ROM Code gets into a loop, waiting for the watchdog to reset the system.

Copyright © 2011, Texas Instruments Incorporated

26.1.5.2 Device List

The ROM Code creates the **device list** based on information gathered from the **SYSBOOT configuration pins** sensed in the control module. The pins are used to index the device table from which the list of devices is extracted

26.1.5.2.1 SYSBOOT Configuration Pins

Table 26-7 contains the SYSBOOT configuration pins.

SYSBOOT Configuration Pins Notes:

1. The buswidth field in the I2C EEPROM for NANDI2C boot mode will override this value.
2. WAIT is monitored on GPMC_WAIT0.
3. MUX1 and MUX2 are defined in Section 26.1.7.2, *XIP Memory*.
4. Note that even though some bits may be a "don't care" for ROM code, all SYSBOOT values are latched into the CONTROL_STATUS register and may be used by software after ROM execution has completed.
5. Boot mode is **not** a permanent booting device. All other boot modes are and will be included in subsequent booting sequences after each watchdog timeout.

Copyright © 2011, Texas Instruments Incorporated

6. SYSBOOT[15:0] terminals are respectively LCD_DATA[15:0] inputs, latched on the rising edge of PWRONRSTn.

Copyright © 2011, Texas Instruments Incorporated

The ROM Code uses the row pointed by the SYSBOOT pins value. The device list is filled in with the 1st to 4th devices.

Table 26-7 is the decoding table for SYSBOOT pin configuration. The following shortcuts are used in the table:

- MMC1: MMC or SD card (MMC port 1)
- MMC0: MMC or SD card (MMC port 0)
- NAND / NANDI2C: NAND flash memory / read geometry from EEPROM on I2C0
- XIP: NOR or other XIP device without wait monitoring
- XIP w/ WAIT: NOR or other XIP device with wait monitoring
- MUX1: Boot with XIP_MUX1 signals detailed in Table 26-9
- MUX2: Boot with XIP_MUX2 signals detailed in Table 26-9
- UART0: UART interface (UART port 0)
- EMAC1: Ethernet interface (EMAC port 1)
- SPI0: SPI EEPROM (SPI 0, CS0)
- USB0: USB interface (USB0)

Note: For any SYSBOOT value that is selected, please be aware of the pin muxing implications. For example, if the boot mode selected is EMAC1, NAND, SPI0, NANDI2C, the device will drive EMAC, GPMC, SPI and I2C pins, in that order, depending on which boot device finally succeeds. Ensure that if a specific boot mode in the sequence chosen is not used that the components using those particular signals do not conflict with the ROM driving those signals (or external components are not in contention with the ROM using these signals). For specific details of the pins driven by each device, please refer the description of that boot device later in this chapter.

To extend the boot flow to boot from devices that are not natively supported by the ROM, SPI boot can be used. For example, to be able to boot from a USB stick, the system can be configured to boot from a SPI flash, and the code for configuring the USB and booting from a USB stick can be loaded into the SPI flash. This is known as a secondary boot.

The values corresponding to SYSBOOT[4:0]= x1111 provide a bypass mode booting feature.

The fast external boot feature consists of minimal execution by the ROM Code for configuring the GPMC interface and then directly jump to the code contained in the connected NOR flash device.

26.1.6 Fast External Booting

26.1.6.1 Overview

The Fast External boot feature:

- Consists of a blind jump in ARM mode to address 0x00000000 in an external XIP device connected to CS0
- The jump is performed with minimum on-chip ROM Code execution (only configures GPMC interface), without configuring any PLL
- Allows the customer to create its own booting code
- Is set up by means of the configuration pins, see Table 26-7.
- Addr/Data muxed device or a non-muxed (selected using SYSBOOT[11:10]) device in connected in MUX1 configuration
- Bus width selected by SYSBOOT[8]
- CS0 chip select
- Device wait signal connected to the WAIT0 GPMC signal (if used)
- The wait monitoring enable/disable is based on the value of SYSBOOT[9]

Copyright © 2011, Texas Instruments Incorporated

26.1.6.2 External Booting

Figure 26-7 shows the Fast External Boot procedure. The code does not make use of RAM and is designed for fast execution.

Figure 26-7. Fast External Boot

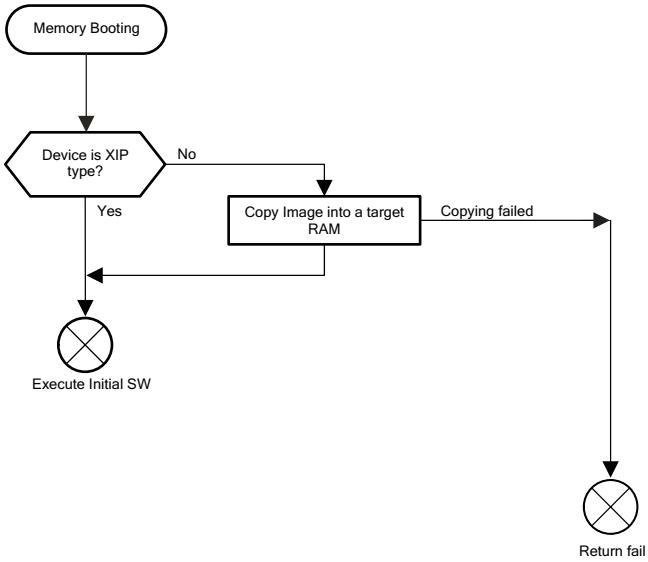
26.1.7 Memory Booting

26.1.7.1 Overview

The memory booting procedure takes care of starting an external code located in memory device types.

Figure 26-8. Memory Booting



There are two groups of memory booting devices distinguished by the need of **code shadowing**. The code shadowing means copying a code from a non-directly addressable device into a location (typically a RAM area) from where the code can be executed. Devices which are directly addressable are called eXecute In Place (XIP) devices.

The Memory Booting flowchart is shown in Figure 26-8. The second step is about performing the shadowing of the image that is copying the image from external mass storage (non-XIP) into internal RAM. Failure in image copy results in Memory Booting returning to the main booting procedure which will select the next device for booting. The next sections detail procedures for device initialization and detection in addition to the description of the sector read routine for each supported device type. A sector is a logical unit of 512 bytes.

The detection of whether an image is present or not on a selected device depends on the first few bytes. On a **GP Device** type a booting image is considered to be present when the first four bytes of the sector is not equal to 0000 0000h or FFFF FFFFh.

During the first read sector call, sectors are copied to a temporary RAM buffer. Once the image is found and destination address is known, the content of the temporary buffer is moved to the target RAM location so it is needed to re-read the first image sector. On a **GP Device** the GP header is discarded, therefore only executable code is located in RAM with the first executable instruction located at the destination address.

The Image authentication and execution is detailed in Section 26.1.10. For more information about image formats and contents, see Section 26.1.9

MMC/SD cards and NAND devices can hold up to four copies of the booting image. Therefore the ROM Code searches for one valid image out of the four if present by walking over the first four blocks of the mass storage space. Other XIP devices (NOR) use only one copy of the booting image.

Copyright © 2011, Texas Instruments Incorporated

26.1.7.2 XIP Memory

The ROM Code can boot directly from XIP devices. A typical XIP device is a NOR flash memory. Support for XIP devices is performed under the following assumptions:

- Uses GPMC as the communication interface
- Up to 1Gbit (128Mbytes) memories can be connected
- Both x8 and x16 data bus width
- Asynchronous protocol
- Supports address/data multiplexed mode and non-muxed mode
- GPMC clock is 50-MHz
- Device connected to CS0 mapped to address 0x8000000h
- Wait pin signal WAIT0 monitored depending on the SYSBOOT pin configuration (XIP / XIP w/ WAIT).
- Flexible muxing options for gpmc_a0-gpmc_a11 for non-muxed XIP devices

Depending on the SYSBOOT pins, the GPMC is configured to use the WAIT signal connected on the WAIT0 pin or not. Wait pin polarity is set to stall accessing memory when the WAIT0 pin is low. The wait monitoring is intended to be used with memories which require long time for initialization after reset or need to pause while reading data. The boot procedure from XIP device can be described as such:

- Configure GPMC for XIP device access.
- Set the image location to 0x8000000h
- Verify if bootable image is present at the image location.
- If the image has been found, start the execution.
- If the image has not been found, return from XIP booting to the main booting loop.

26.1.7.2.1 XIP Initialization and Detection

- GPMC initialization

Figure 26-9 and Table 26-8 describe the GPMC timing settings set for XIP boot and other address-data accessible devices.

Copyright © 2011, Texas Instruments Incorporated

Figure 26-9. GPMC XIP Timings

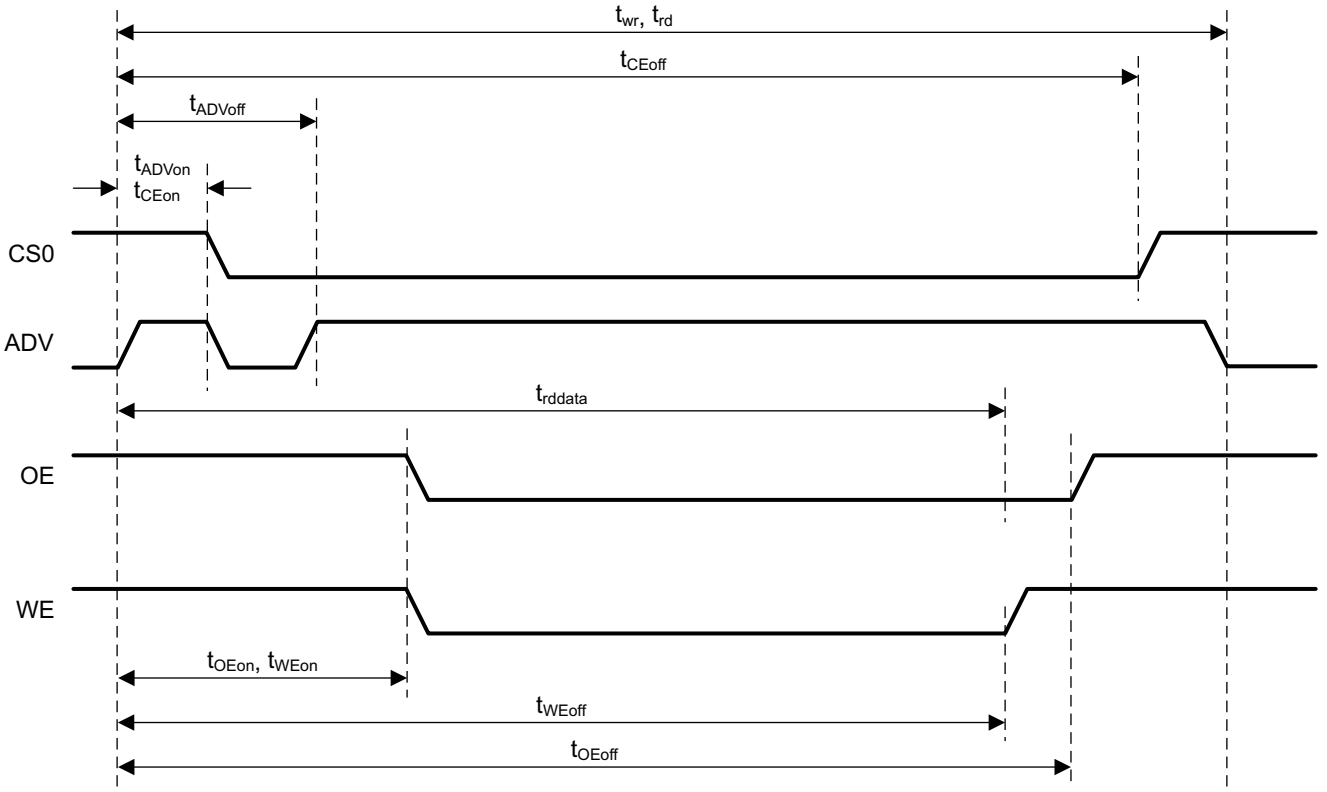


Table 26-8. XIP Timings Parameters

Parameter	Description	Value [clock cycles]
t_{wr}	write cycle period	17
t_{rd}	read cycle period	17
t_{CEon}	CE low time	1
t_{CEoff}	CE high time	16
t_{ADVon}	ADV low time	1
t_{ADVoff}	ADV high time	2
t_{OEon}	OE low time	3
t_{WEon}	WE low time	3
t_{rddata}	data latch time	15
t_{OEoff}	OE high time	16
t_{WEoff}	WE high time	15

Copyright © 2011, Texas Instruments Incorporated

The one clock cycle is 20ns, which corresponds to 50-MHz frequency.

- Device detection

There is no specific identification routine executed prior to booting from an XIP device.

26.1.7.2.2 Pins Used

The list of device pins that are configured by the ROM incase of NOR boot mode are as follows. Please note that all the pins might not be driven at boot time. The decision as to which pins need to be driven is done based on the type of NOR flash selected. The pins that are not listed below are not configured by the ROM code and are left at power-on defaults. Specifically, external logic is needed to isolate the upper address lines (A12–A27) of the NOR flash from the device pins and drive them low during boot. Once the initial software starts running, it can appropriately configure the pinmux setting for the lines and remove the isolation to allow GPMC to drive all the address lines.

Table 26-9. Pins Used for NOR Boot

Signal name	Pin used in XIP_MUX1 mode	Pin used in XIP_MUX2 mode
CS0	GPMC_CSN0	GPMC_CSN0
ADVN_ALE	GPMC_ADVN_ALE	GPMC_ADVN_ALE
OEN_REN	GPMC_OEN_REN	GPMC_OEN_REN
BEN0_CLE	GPMC_BEN0_CLE	GPMC_BEN0_CLE
WEN	GPMC_WEN	GPMC_WEN
WAIT	GPMC_WAIT0	GPMC_WAIT0
AD0 - AD15	GPMC_AD0 - GPMC_AD15	GPMC_AD0 - GPMC_AD15
A0	GPMC_A0	LCD_DATA0
A1	GPMC_A1	**LCD_DATA1**
A2	**GPMC_A2**	**LCD_DATA2**
A3	**GPMC_A3**	**LCD_DATA3**
A4	**GPMC_A4**	**LCD_DATA4**
A5	GPMC_A5	LCD_DATA5
A6	**GPMC_A6**	**LCD_DATA6**
A7	**GPMC_A7**	LCD_DATA7
A8	**GPMC_A8**	LCD_VSYNC
A9	**GPMC_A9**	LCD_HSYNC
A10	**GPMC_A10**	LCD_PCLK
A11	**GPMC_A11**	LCD_AC_BIAS_EN

26.1.7.2.3 Sysboot Pins

Some of the SYSBOOT pins have special meanings when NOR boot is selected.

Table 26-10. Special SYSBOOT Pins for NOR Boot

SYSBOOT[n]	Description
[8]	0 = 8-bit device 1 = 16-bit device
[11:10]	00b = Non-muxed device 10b = Muxed device x1b = Reserved

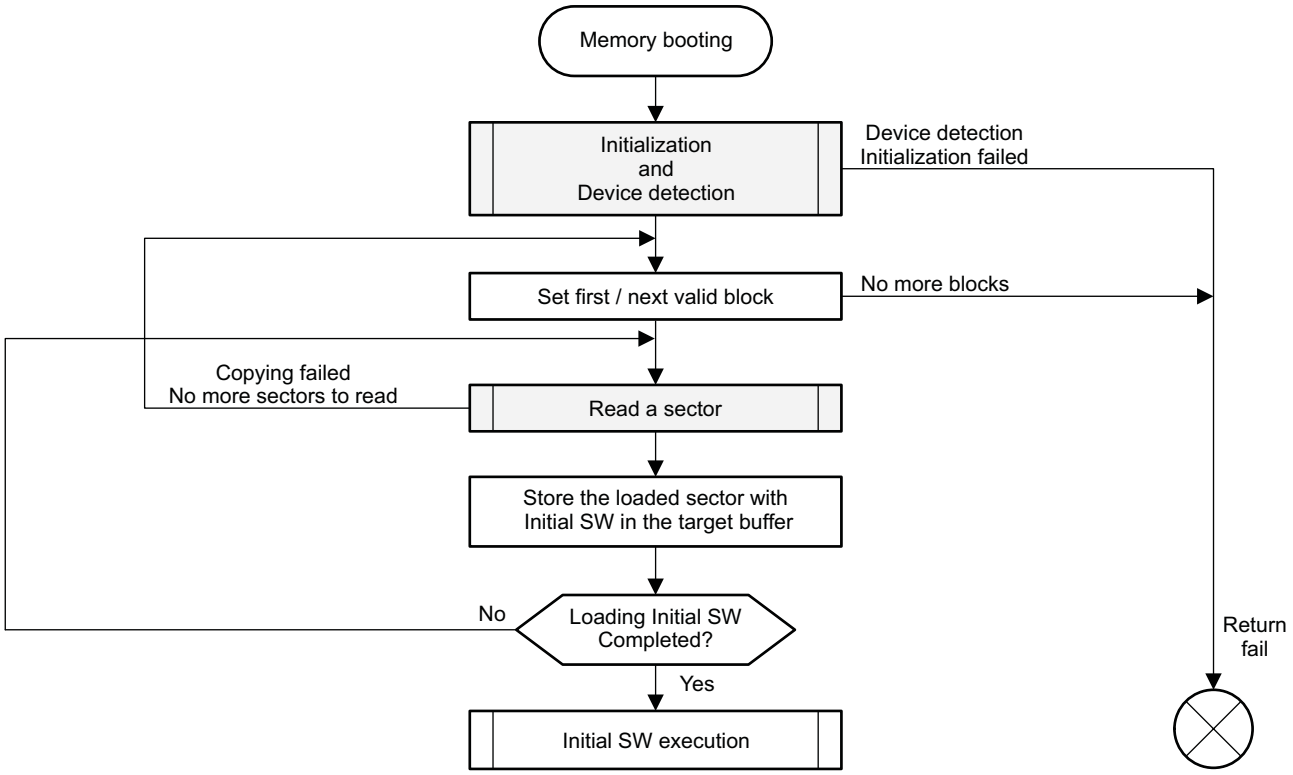
26.1.7.2.4 Image Shadowing for Non-XIP Memories

26.1.7.2.4.1 Shadowing on GP Device

The **GP Device** shadowing uses the following approach.

Copyright © 2011, Texas Instruments Incorporated

Figure 26-10. Image Shadowing on GP Device



26.1.7.2.5 NAND

The NAND flash memory is not XIP and requires shadowing before the code can be executed.

26.1.7.2.5.1 Features

- Uses GPMC as the communication interface
- Device from 512Mbit (64MByte)
- x8 and x16 bus width
- Support for large page size (2048 bytes + 64 spare bytes) or very large page size 4096 bytes + 128 / 218 spare bytes)
- Only supports devices where Chip Select can be de-asserted during read, program or erase cycles, without interrupting the operation
- Single Level Cell (SLC) and Multiple Level Cell (MLC) devices
- Device Identification based on ONFI or ROM table
- ECC correction : 8 bits/sector for most devices (16b/sector for devices with large spare area)
- Support for disabling ECC correction, so than the in-built ECC correction mechanisms on some NANDs can be used.
- GPMC timings adjusted for NAND access
- GPMC clock is 50MHz
- Device connected to GPMC_CSN0
- Wait pin signal GPMC_WAIT0 connected to NAND BUSY output
- Four physical blocks are searched for an image. The block size depends on device.

Copyright © 2011, Texas Instruments Incorporated

26.1.7.2.5.2 Initialization and Detection

The initialization routine for NAND devices consists in three parts: GPMC initialization, device detection with parameters determination and finally bad block detection.

ONFI Support

The NAND identification starts with ONFI detection. For more information on ONFI standard, see the Open NAND Flash Interface Specification (http://www.onfi.org).

GPMC Initialization

The GPMC interface is configured as such it can be used for accessing NAND devices. The address bus is released since a NAND device does not use it. The data bus width is initially set to 8 bits; and changed to 16 bits if needed after device parameters determination. The following scheme is applied since NAND devices require different timings when compared to regular NOR devices:

Figure 26-11. GPMC NAND Timings

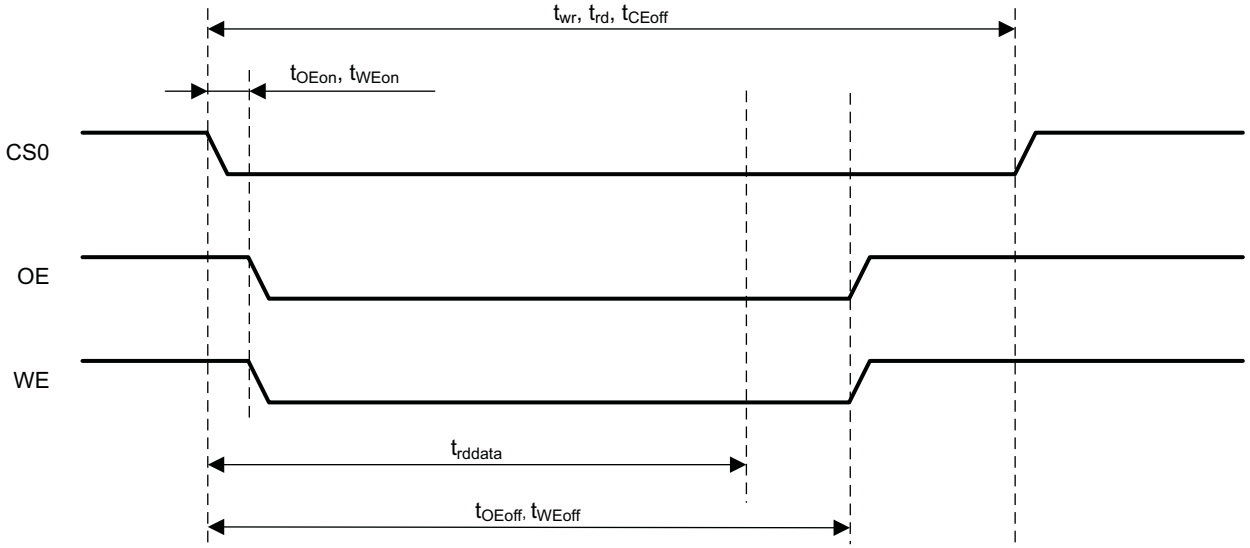


Table 26-11. NAND Timings Parameters

Parameter	Description	Value [clock cycles]
t_{wr}	write cycle period	30
t_{rd}	read cycle period	30
t_{CEon}	CE low (not marked on the figure)	0
t_{OEon}	CE low to OE low time	7
t_{WEon}	CE low to WE low time	5
t_{rddata}	CE low to data latch time	21
t_{OEoff}	CE low to OE high time	24
t_{WEoff}	CE low to WE high time	22

Copyright © 2011, Texas Instruments Incorporated

Figure 26-11 and Table 26-11 describes the timings configured for NAND device access. The one clock cycle is 20 ns, which correspond to 50-MHz frequency.

Device Detection and Parameters

The ROM Code first performs an initial wait for device auto initialization (with 250ms timeout) with polling of the ready information. Then, it needs to identify the NAND type connected to the GPMC interface. The GPMC is initialized using 8 bits, asynchronous mode. The NAND device is reset (command FFh) and its status is polled until ready for operation (with 200ms timeout). The ONFI Read ID (command 90h / address 20h) is sent to the NAND device. If it replies with the ONFI signature (4 bytes) then a Read parameters page (command ECh) is sent. If the parameters page does not have the ONFI signature, then the ONFI identification fails. If the ONFI identification passes, the information shown in Table 26-12 is then extracted: page size, spare area size, number of pages per block, and the addressing mode. The remaining data bytes from the parameters page stream are simply ignored.

Table 26-12. ONFI Parameters Page Description

Offset	Description	Size (bytes)
6	Features supported	2
80	Number of data bytes per page	4
84	Number of spare bytes per page	2
92	Number of pages per block	4
101	Number of address cycles	1

If the ONFI Read ID command fails (it will be the case with any device not supporting ONFI) then the device is reset again with polling for device to be ready (with 200ms timeout). Then, the standard Read ID (command 90h / address 00h) is sent. If the Device ID (2nd byte of the ID byte stream) is recognized as being a supported device then the device parameters are extracted from an internal ROM Code table. The list of supported devices is shown in Table 26-13.

Table 26-13. Supported NAND Devices

Capacity	Device ID	Bus Width	Page size
512 Mb	F0	x8	2048
512 Mb	C0	x16	2048

32 Gb	97	x16	2048
64 Gb	DE	x8	2048/4096
64 Gb	CE	x16	2048/4096
64 Gb	AE	x8	2048/4096
64 Gb	BE	x16	2048/4096

When the parameters are retrieved from the ROM table: page size and block size is updated based on 4th byte of NAND ID data. Due to inconsistency amongst different manufacturers, only devices which has been recognized to be at least 2Gb (included) have these parameters updated. Therefore, the ROM Code supports 4kB page devices but only if their size, according to the table, is at least 2Gb. Devices which are smaller than 2Gb have the block size parameter fixed to 128kB. Table 26-14 shows the 4th ID Data byte encoding used in ROM Code.

Table 26-14. 4th NAND ID Data Byte

Item	Description	I/O #							
		7	6	5	4	3	2	1	0

Reading NAND Geometry From I2C EEPROM

ROM supports a special boot mode called NANDI2C to support NAND devices whose geometry cannot be detected by the ROM automatically using methods described in the previous section. If this boot mode is selected, the ROM code tries to read NAND geometry from an I2C EEPROM. If the read is successful, ROM code then proceeds to next steps of NAND boot, beginning with reading bad blocks information.

Note: The NAND bus width configuration mentioned in the I2C EEPROM overrides the BUSWIDTH configuration selected by SYSBOOT[8] pin.

The list of device pins that are configured by the ROM incase of NANDI2C boot mode. (This is in addition to the NAND boot pins described in the previous sections.)

Table 26-15. Pins Used for NANDI2C Boot for I2C EEPROM Access

Signal name	Pin Used in Device
I2C SCL	**i2c0_scl**
I2C SDA	**i2c0_sda**

ROM accesses the I2C EEPROM at I2C slave address **0x50** and reads 7 bytes starting from address offset **0x80**. The format of this (NAND geometry information) is as follows:

Table 26-16. NAND Geometry Information on I2C EEPROM

Byte address	Information	
	Upper nibble	Lower nibble
0x80	Magic Number – 0x10	
0x81	Magic Number – 0xb3	
0x82	Magic Number – 0x57	
0x83	Magic Number – 0xa6	
0x84	NAND column address (word/byte offset within a page) size in bytes, Example: 2	NAND row address (page offset) size in bytes. Example: 3
0x85	Page size (2^N) exponent “N”. Example (for page size of 2048): 11	Pages per block (2^N) exponent “N”Example (for number of blocks 64): 6
0x86	NAND bus width 0 = 8-bit device 1 = 16-bit device	ECC Type 00b = No ECC 01b = BCH8 10b = BCH16 11b = Reserved

- ECC correction

The default ECC correction applied is BCH 8b/sector using the GPMC and ELM hardware.

For device ID codes D3h, C3h, D5h, C5h, D7h, C7h, DEh, CEh when manufacturer code (first ID byte) is 98h the Cell type information is checked in the 4th byte of ID data. If it is equal to 10b then the ECC correction applied is BCH 16b/sector.

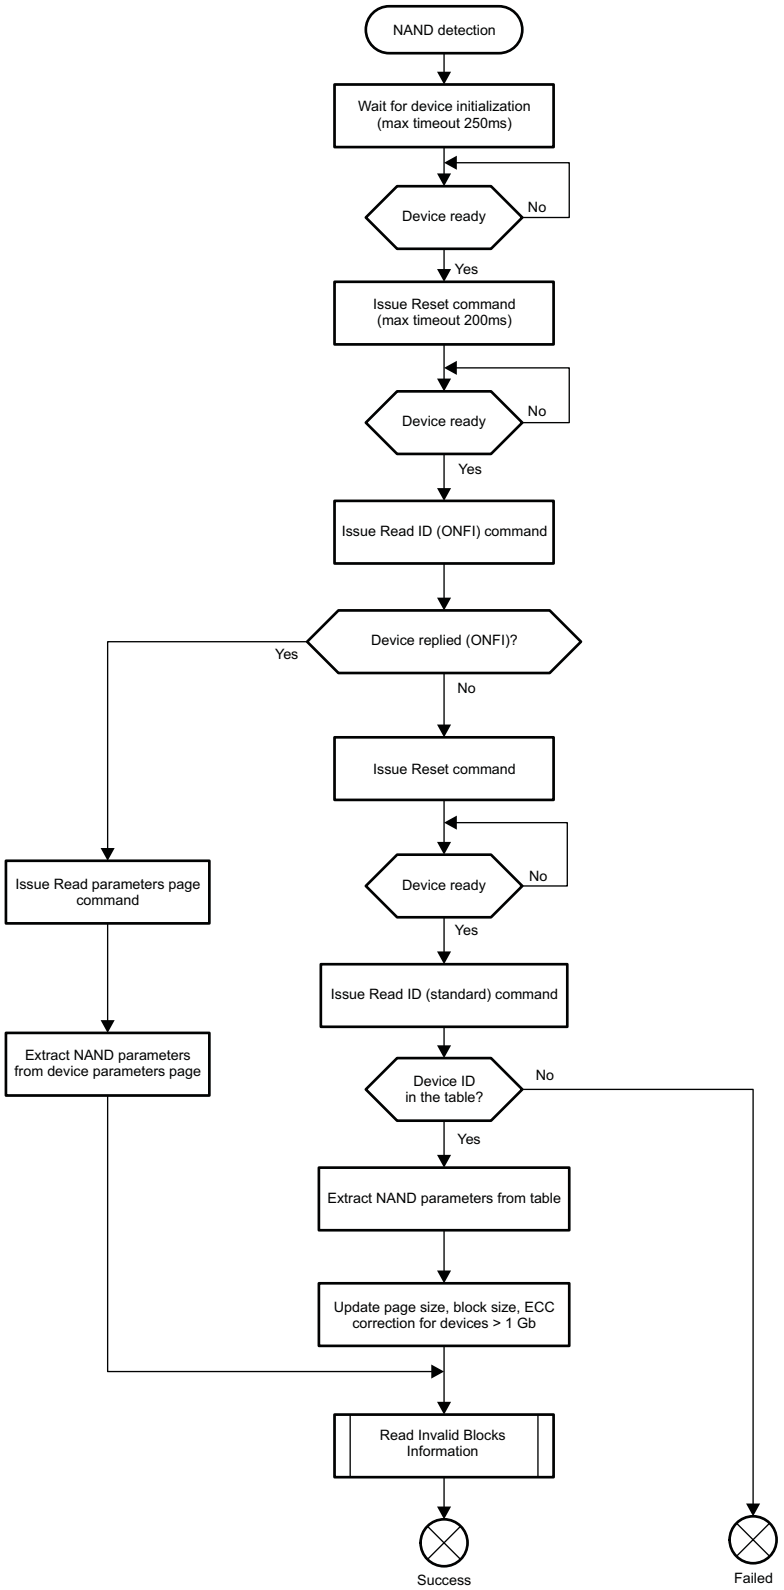
In addition ECC computation done by the ROM can be turned off completely by using SYSBOOT[9]. This is particularly useful when interfacing with NAND devices that have built in ECC engines.

Table 26-17. ECC Configuration for NAND Boot

SYSBOOT[9]	ECC Computation
0	ECC done by ROM
1	ECC handled by NAND

Copyright © 2011, Texas Instruments Incorporated

Figure 26-12. NAND Device Detection



The detection procedure is described in Figure 26-12. Once the device has been successfully detected, the ROM Code changes GPMC to 16-bit bus width if necessary.

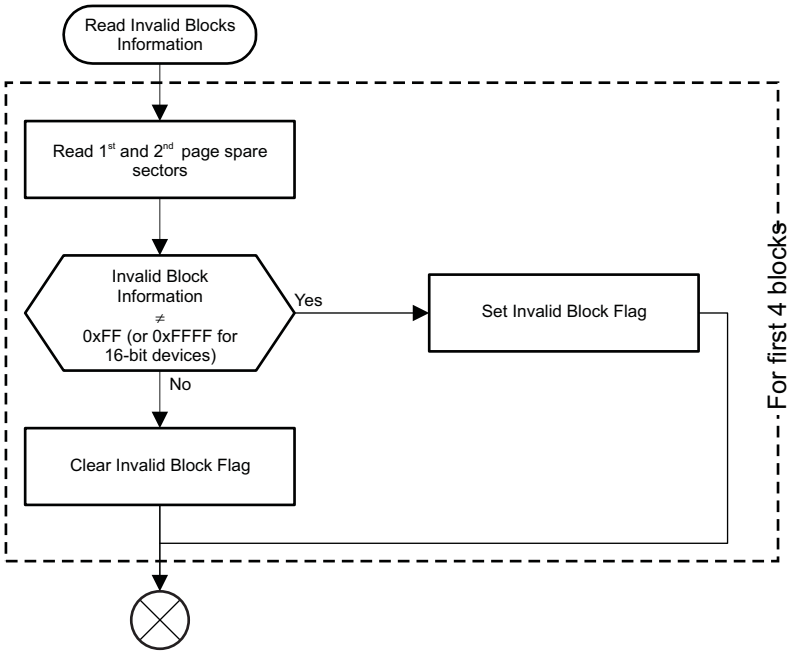
Copyright © 2011, Texas Instruments Incorporated

Bad Block Verification

Invalid blocks are blocks which contain invalid bits whose reliability cannot be guaranteed by the manufacturer. Those bits are identified in the factory or during the programming and reported in the initial invalid block information located in the spare area on the 1st and 2nd page of each block. Since the ROM Code is looking for an image in the first four blocks, it must detect block validity status of these blocks. Blocks which are detected as invalid are not accessed later on. Blocks validity status is coded in the spare areas of the first two pages of a block (first byte equal to FFh in 1st and 2nd pages for an 8 bits device / first word equal to FFFFh in 1st and 2nd page for a 16bits device).

Figure 26-13 depicts the invalid block detection routine. The routine consists in reading spare areas and checking validity data pattern.

Figure 26-13. NAND Invalid Blocks Detection



26.1.7.2.5.2.1 NAND Read Sector Procedure

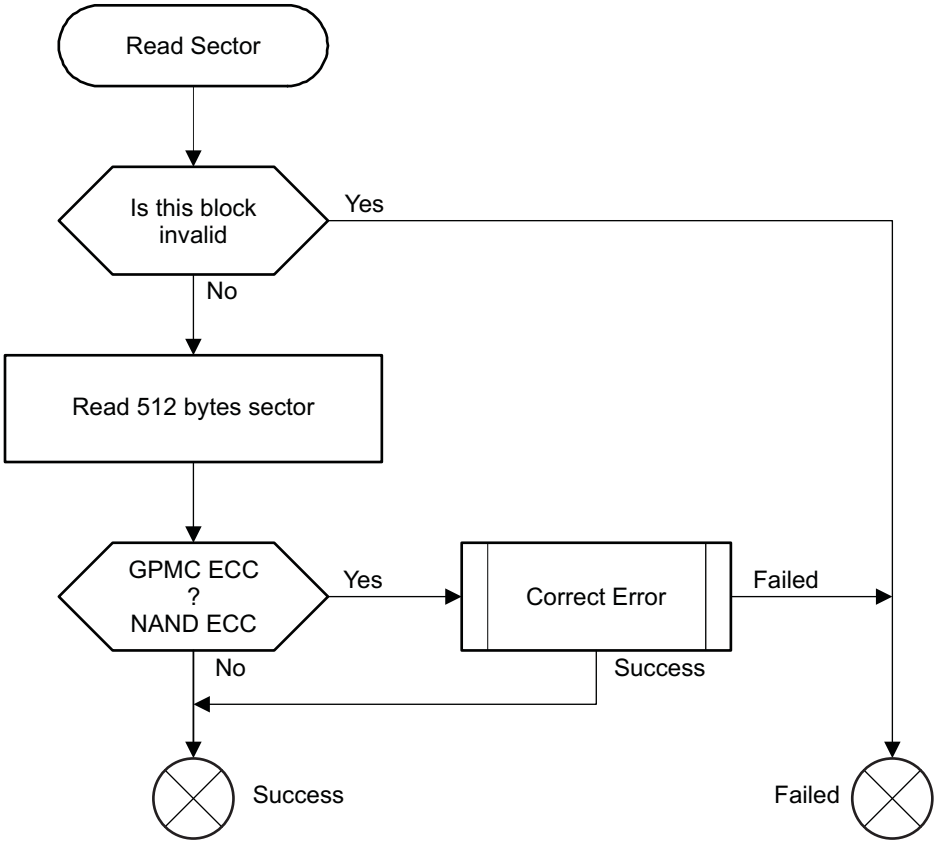
The ROM Code reads data from NAND devices in 512 bytes sectors. The read function fails in two cases:

- The accessed sector is within a block marked as invalid
- The accessed sector contains an error which cannot be corrected with ECC

Figure 26-14 shows the read sector routine for NAND devices. The ROM Code uses normal read (command 00h 30h) for reading NAND page data.

Copyright © 2011, Texas Instruments Incorporated

Figure 26-14. NAND Read Sector Procedure



Page data can contain errors due to memory alteration. The ROM Code uses an ECC correction algorithm to detect and possibly correct those errors. The ECC algorithm used is BCH with capability for correcting 8b or 16b errors per sector. The BCH data is automatically calculated by the GPMC on reading each 512 bytes sector. The computed ECC is compared against ECC stored in the spare area for the corresponding page. Depending on the page size, the amount of ECC data bytes stored in the corresponding spare area is different. Figure 26-15 and Figure 26-16 show the mapping of ECC data inside the spare area for respectively 2KB-page and 4KB- page devices. If both ECC data are equal then the Read Sector function returns the read 512 bytes sector without error. Otherwise the ROM Code tries to correct error(s) in the corresponding sector (this procedure is assisted by the ELM hardware) and returns the data if successful. If errors are uncorrectable, the function returns with FAIL.

26.1.7.2.5.2.3 Sysboot Pins

Some of the SYSBOOT pins have special meanings when NAND boot is selected.

Table 26-19. Special SYSBOOT Pins for NAND Boot

SYSBOOT[n]	Description
[8]	0 = 8-bit NAND 1 = 16-bit NAND
[11:10]	Must be 0

26.1.7.2.6 MMC / SD Cards

26.1.7.2.6.1 Overview

The ROM Code supports booting from MMC / SD cards in the following conditions:

- MMC/SD Cards compliant to the Multimedia Card System Specification and Secure Digital I/O Card Specification of low and high capacities.
- MMC/SD cards connected to MMC0 or MMC1.
- Support for 3.3/1.8 V on MMC0, or 1.8 V on MMC1.
- Initial 1-bit MMC Mode, optional 4-bit mode, if device supports it.
- Clock Frequency: identification mode: 400 KHz; data transfer mode up to 10 MHz.
- Only one card connected to the bus.
- Raw mode, image data read directly from sectors in the user area.
- File system mode (FAT12/16/32 supported with or without Master Boot Record), image data is read from a booting file.

26.1.7.2.6.2 System Interconnection

An MMC/SD card can be connected to the **MMC0 interface** typically through a card cage.

An eMMC/eSD/managed NAND memory device can be connected to **MMC1 interface**.

Note:

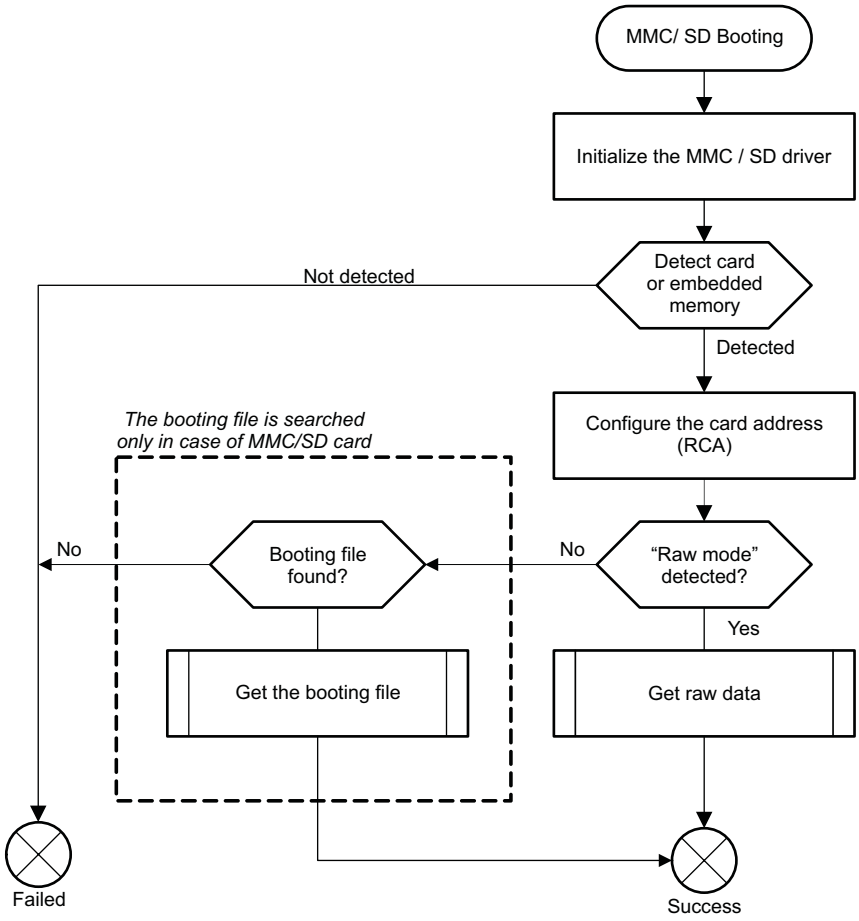
- The ROM Code does not handle the card detection feature on card cage.
- If MMC1 is used the GPMC interface is not usable, due to pin muxing options.
- MMC1 supports sector mode without querying the card.

26.1.7.2.6.3 Booting Procedure

The high level flowchart of the eMMC / eSD and MMC/SD booting procedure is depicted in Figure 26-17. The booting file is searched only in case of booting from a card. eMMC/eSD embedded memories only support raw mode.

Copyright © 2011, Texas Instruments Incorporated

Figure 26-17. MMC/SD Booting



26.1.7.2.6.4 Initialization and Detection

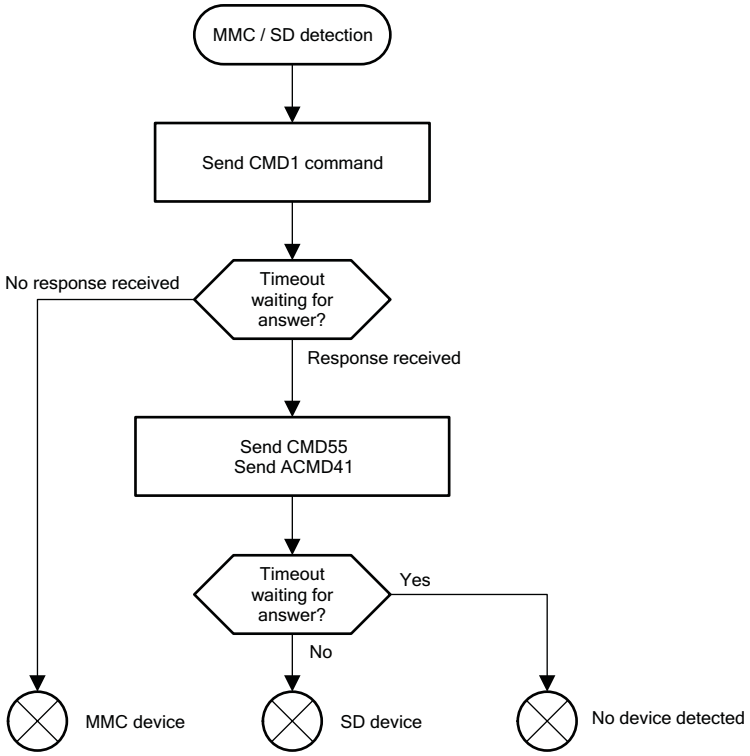
The ROM Code initializes the memory device or card connected on MMC interface using the standard High-Voltage range (3.3 V). If neither memory device nor card is detected then the ROM Code carries on to the next booting device. The standard identification process and **Relative Card Address (RCA)** assignment are used. However, the ROM Code assumes that only one memory or card is present on the bus. This first sequence is done using the CMD signal which is common to SD and MMC devices.

MMC and SD standards detail this phase as **initialization phase**. Both standards differ in the first commands involved: **CMD1** and **ACMD41**. The ROM Code uses this difference in command set to discriminate between MMC and SD devices: CMD1 is supported only by the MMC standard whereas ACMD41 is only supported by SD standard. The ROM Code first sends a CMD1 to the device and gets a response only if an MMC device is connected. If no response is received then ACMD41 (ACMD41 is made out of CMD55 and ACMD41) is sent and a response is expected from an SD device. If no response is received then it is assumed that no device is connected and the ROM Code exits the MMC/SD Booting procedure with FAIL. This is detection procedure shown in Figure 26-18.

Another point to note is the difference in the arguments to CMD1 between MMC0 and MMC1. At first the ROM queries the card with CMD1, ARG = 0, to get the OCR from the card. On MMC0, the response from the card is simply reflected back to the card as the argument for all subsequent CMD1, till the card is in the READY state. On MMC1, Bit30 of the response received from the card is set to 1 by the ROM, and this modified value is used as the argument for subsequent CMD1. This is done to indicate to the card that the ROM supports sector addressing. This mode might not be compatible with older (older than v4.4) versions of cards.

Copyright © 2011, Texas Instruments Incorporated

Figure 26-18. MMC/SD Detection Procedure



As previously mentioned the contents of an MMC/SD card may be formatted as raw binary or within a FAT filesystem. eMMC / eSD devices only support raw mode. The ROM Code reads out raw sectors from image or the booting file within the file system and boots from it.

26.1.7.2.6.5 MMC/SD Read Sector Procedure in Raw mode

In raw mode the booting image can be located at one of the four consecutive locations in the main area: offset 0x0 / 0x20000 (128 KB) / 0x40000 (256 KB) / 0x60000 (384 KB). For this reason, a booting image shall not exceed 128KB in size. However it is possible to flash a device with an image greater than 128KB starting at one of the aforementioned locations. Therefore the ROM Code does not check the image size. The only drawback is that the image will cross the subsequent image boundary.

The raw mode is detected by reading sectors #0, #256, #512, #768. The content of these sectors is then verified for presence of a TOC structure as described in Section 26.1.9. In the case of a **GP Device**, a Configuration Header (CH) **must** be located in the first sector followed by a **GP header**. The CH might be void (only containing a CHSETTINGS item for which the Valid field is zero).

26.1.7.2.6.6 MMC/SD Read Sector Procedure in FAT Mode

MMC/SD Cards may hold a FAT file system which ROM Code is able to read and process. The image used by the booting procedure is taken from a specific booting file named “MLO”. This file has to be located in the root directory on an active primary partition of type FAT12/16 or FAT32.

An MMC/SD card can be configured either as floppy-like or hard-drive-like.

- When acting as floppy-like, the content of the card is a single file system without any Master Boot Record (MBR) holding a partition table
- When acting as hard-drive-like, an MBR is present in the first sector of the card. This MBR holds a table of partitions, one of which must be FAT12/16/32, primary and active.

Copyright © 2011, Texas Instruments Incorporated

The card should always hold an MBR except for MMC cards using floppy-like file system (please refer to the CSD internal Register fields FILE_FORMAT_GRP and FILE_FORMAT in the MultiMedia Card System Specification). However, depending on the used operating system the MMC/SD card will be formatted either with partition(s) (using an MBR) or without. The ROM Code supports both types; this is described in the following section.

The ROM Code retrieves a map of the booting file from the FAT table. The booting file map is a collection of all FAT table entries related to the booting file (a FAT entry points to a cluster holding part of the file). The booting procedure uses this map to access any 512 byte sector within the booting file without involving ROM Code FAT module.

The sector read procedure utilizes standard MMC/SD raw data read function. The sector address is generated based on the booting memory file map collected during the initialization. Hence the ROM Code can address sectors freely within the booting file space.

26.1.7.2.6.7 FAT File system

This paragraph describes functions which are used by the ROM Code, it is not intended to fully describe the Master Boot Record and the FAT file system:

- How to recognize if a sector is the 1st sector of an MBR
- How to recognize if a sector is the 1st sector of a FAT12/16/32
- How to find the 1st cluster of the booting file
- How to buffer the booting file FAT entries.

Some memory devices which support file systems can be formatted with or without MBR, therefore the first task of the ROM Code is to detect whether or not the device is holding an MBR in the first sector.

If this is the case, an active FAT12/16/32 partition is searched in all 4 MBR partition entries, based on the Type field. If the MBR entries are not valid or if no useable partition is found then the ROM Code returns to the Booting procedure with FAIL. The Extended partitions are not checked, the booting file must reside in a primary partition.

If a partition is found then its first sector is read and used further on. If no MBR is present (in case of a floppy-like system), the first sector of the device is read and used further on.

The read sector is checked to be a valid FAT12/16 or FAT32 partition. If this fails, in case another partition type is used (i.e. Linux FS or any other) or if the partition is not valid, the ROM Code returns with FAIL.

Otherwise, the Root Directory entries are searched for a file named depending on the booting device. The Long File Names (LFN) format is not used and **only File Names in 8.3 Format are searched for**. If no valid file is found, the ROM Code returns with FAIL.

Once the file has been found, the ROM Code reads the File Allocation Table (FAT) and buffers the singly-linked chain of clusters in a FAT Buffer which will be used by the Booting Procedure to access the file directly sector by sector. For FAT12/16 and for FAT32 (valid if a specific flag has been set in the FAT32 Boot Sector), there exist multiples copies of the FAT (ROM Code supports only 2 copies). When buffering FAT entries, the 2 FATs are compared. If they are not the same, only entries from the last FAT are used. The FAT Buffer holds sector numbers and not cluster numbers. The ROM Code converts each cluster entry to one or several sector entries if applicable.

The whole process is described in Figure 26-19. Every part related to MBR or FAT12/16/32 is described in the next paragraph.

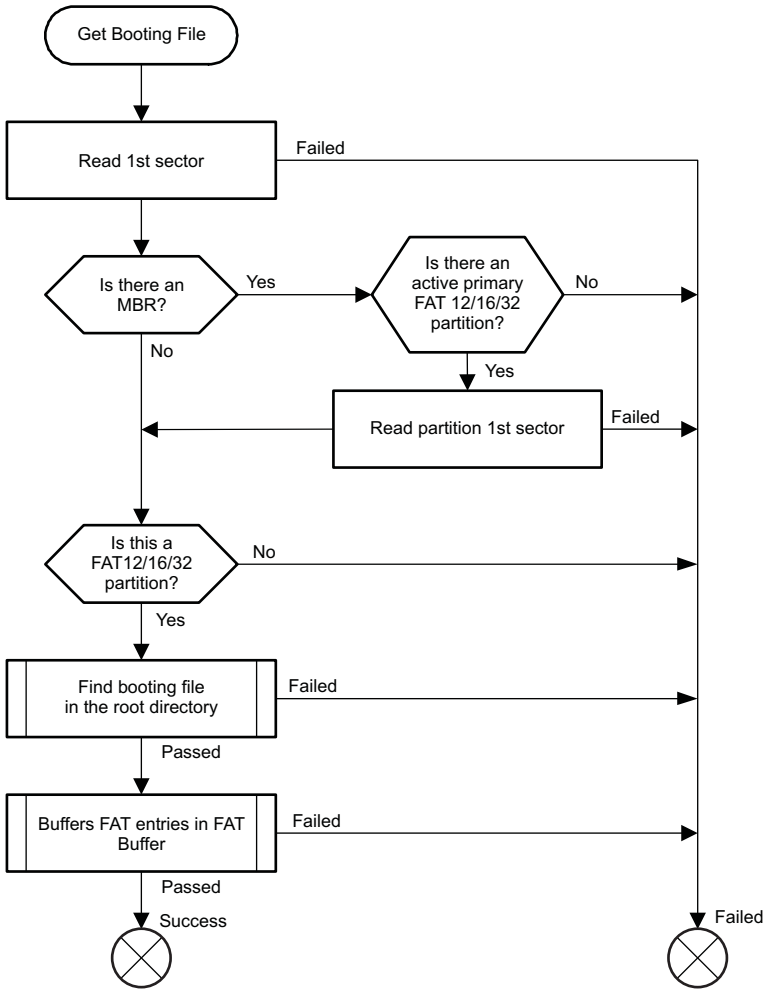
Figure 26-19. MMC/SD Booting, Get Booting File



26.1.7.2.6.7.1 Master Boot Record (MBR)

The Master Boot Record is the 1st sector of a memory device. It is made out of some executable code and 4 partition entries. The aim of such a structure is to be able to divide the hard disk in partitions mostly used to boot different systems (i.e. Microsoft Windows™, Linux, …). Its structure is described in Table 26-20 and Table 26-21. The valid partition types searched by the ROM Code are described in Table 26-22.

Table 26-20. Master Boot Record Structure

Offset	Length[bytes]	Entry Description	Value
0000h	446	Optional Code	
01BEh	16	Partition Table Entry	(see Table 26-21)
01CEh	16	Partition Table Entry	(see Table 26-21)
01DEh	16	Partition Table Entry	(see Table 26-21)
01EEh	16	Partition Table Entry	(see Table 26-21)
01FEh	2	Signature	AA55h

Copyright © 2011, Texas Instruments Incorporated

Table 26-21. Partition Entry

Offset	Length[bytes]	Entry Description	Value
0000h	1	Partition State	00h: Inactive80h: Active
0001h	1	Partition Start Head	H_s
0002h	2	Partition Start Cylinder and Sector	C_s[7:0]-C_s[9:8]-S_s[5:0]
0004h	1	Partition Type	See Table 26-22 for partial partition types
0005h	16	Partition End Head	H_e
0006h	2	Partition End Cylinder and Sector	C_e[7:0]-C_e[9:8]-S_e[5:0]
0008h	4	First sector position relative to the beginning of media	$LBA_s=C_s.H.S+ H_s.S+ S_s-1$
000Ch	4	Number of sectors in partition	$LBA_e=C_e.H.S+ H_e.S+ S_e-1Nbs= LBA_e-LBA_s+1$

Table 26-22. Partition Types

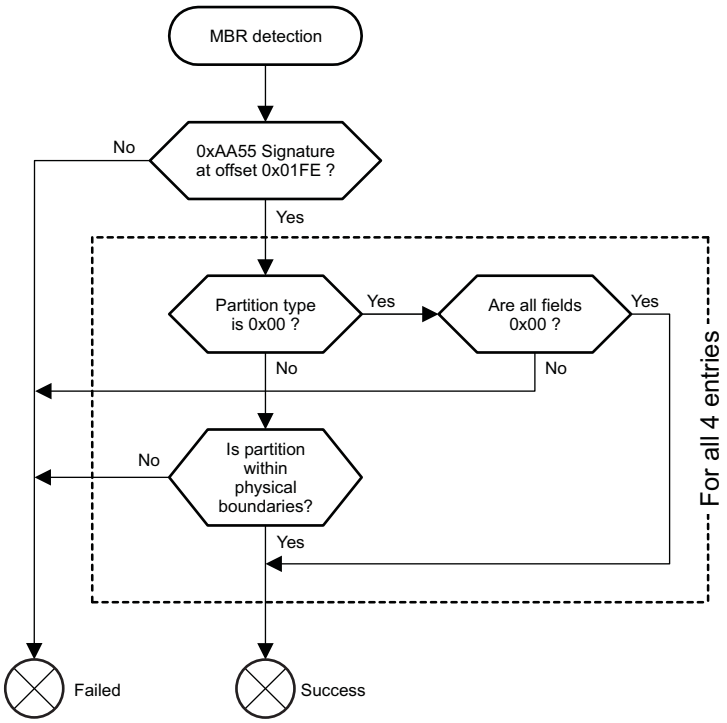
Partition Type	Description
01h	FAT12
04h, 06h, 0Eh	FAT16
0Bh, 0Ch, 0Fh	FAT32

The way the ROM Code detects whether a sector is the 1st sector of an MBR or not is described in Figure 26-20.

The ROM Code first checks if the signature is present. Each partition entry is checked:

- If its type is set to 00h then all fields in the entry must be 00h
- The partition is checked to be within physical boundaries, i.e. the partition is located inside and it's size fits the total physical sectors.

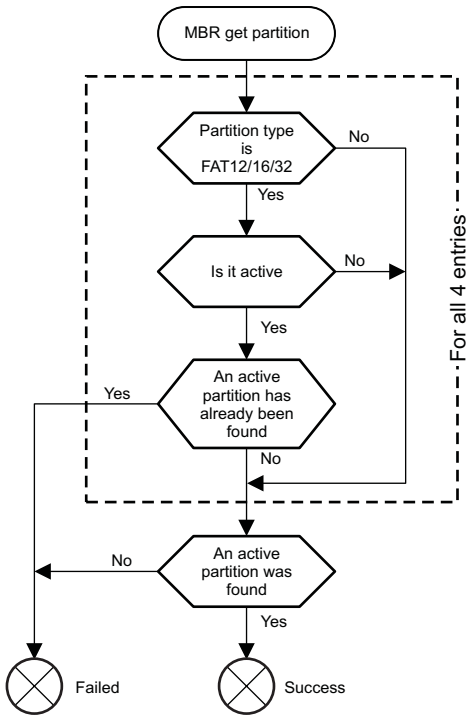
Figure 26-20. MBR Detection Procedure



Copyright © 2011, Texas Instruments Incorporated

Once identified, the ROM Code gets the partition using the procedure described in Figure 26-21. The partition type is checked to be FAT12/16 or FAT32. Its state must be 00h or 80h (if there are more than one active partition the test fails). The ROM Code returns with FAIL if no active primary FAT12/16/32 could be found.

Figure 26-21. MBR, Get Partition



26.1.7.2.6.7.2 FAT12/16/32 Boot Sector

The FAT file system is made out of several parts:

- Boot Sector which holds the BIOS Parameter Block (BPB)
- File Allocation Table (FAT) which describes the use of each cluster of the partition
- Data Area which holds the Files, Directories and Root Directory (for FAT12/16, the Root Directory has a specific fixed location).

The Boot Sector is described in Table 26-23.

Note: In the following description, all the fields whose names start with BPB_ are part of the BPB. All the fields whose names start with BS_ are part of the Boot Sector and not really part of the BPB (not mandatory), they are not used at all by the ROM Code.

Table 26-23. FAT Boot Sector

Offset	Length[bytes]	Name	Description
0000h	3	BS_jmpBoot	Jump Instruction to Boot Code (not used)
0003h	8	BS_OEMName	Name of the System which created the partition
000Bh	2	BPB_BytsPerSec	Counts of Bytes per sector (usually 512)
000Dh	1	BPB_SecPerClus	Number of sectors per allocation unit
000Eh	2	BPB_RsvdSecCnt	Number of reserved sectors for the Boot SectorFor FAT12/16 is 1, for FAT32, usually 32
0010h	1	BPB_NumFATs	Number of copies of FAT, usually 2

Copyright © 2011, Texas Instruments Incorporated

Table 26-23. FAT Boot Sector (continued)

Offset		Length[bytes]	Name	Description
0011h		2	BPB_RootEntCnt	For FAT12/16, number of 32 bytes entries in the Root Directory (multiple of BPB_BytsPerSec/32)For FAT32 this value is 0
0013h		2	BPB_TotSec16	Total Count of sectors on the volume. If the size is bigger than 10000h or for FAT32, this field is 0 and BPB_TotSec32 holds the value
0015h		1	BPB_Media	Media Type, usually F8h: fixed, non-removable
0016h		2	BPB_FATSz16	For FAT12/16, size in sectors of one FATFor FAT32, holds 0
0018h		2	BPB_SecPerTrk	Number of sectors per track, 63 for SD/MMC
001Ah		2	BPB_NumHeads	Number of heads, 255 for SD/MMC
001Ch		4	BPB_HiddSec	Number of sectors preceeding the partition
0020h		4	BPB_TotSec32	Total Count of sectors on the volume. If the size is smaller than 10000h (for FAT12/16), this field is 0 and BPB_TotSec16 is valid
FAT12/16	0024h	1	BS_DrvNum	Drive Number
	0025h	1	BS_Reserved1	00h
	0026h	1	BS_BootSig	Extended Boot Signature 29h. Indicates that the following 3 fields are present
	0027h	4	BS_VolID	Volume Serial Number
	002Bh	11	BS_VolLab	Volume Label
	0036h	8	BS_FilSysType	File system Type: “FAT12”, “FAT16”, “FAT32”.Note: This field is not mandatory (i.e BS_) therefore it cannot be used to indentify the partition type.

Copyright © 2011, Texas Instruments Incorporated

Table 26-23. FAT Boot Sector (continued)

Offset		Length[bytes]	Name	Description	
FAT32	0024h	4	BPB_FATSz32	Size in sectors of one FAT. Field BPB_FATSz16 must be 0	
	0028h	2	BPB_ExtFlags	FAT Flags:	
				[7]:	0=FAT is mirrored; 1=Only one FAT is used
				[3:0]:	Number of used FAT if no mirroring used
	002Ah	2	BPB_FSVer	File system Version Number	
	002Ch	4	BPB_RootClus	First Cluster number of the Root Directory	
	0030h	2	BPB_FSInfo	Sector number of FSINFO Structure in the reserved-area, usually 1	
	0032h	2	BPB_BkBootSec	If non-zero, indicates the sector number in the reserved-area of a copy of the Boot Sector	
	0034h	12	BPB_Reserved	Reserved, set to 00h	
	0040h	1	BS_DrvNum	Drive Number	
	0041h	1	BS_Reserved1	00h	
	0042h	1	BS_BootSig	Extended Boot Signature 29h. Indicates that the following 3 fields are present	
	0043h	4	BS_VolID	Volume Serial Number	
	0047h	11	BS_VolLab	Volume Label	
	0052h	8	BS_FilSysType	File system Type: “FAT12”, “FAT16”, “FAT32”.Note: This field is not mandatory (i.e BS_) therefore it cannot be used to indentify the partition type.	
01FEh		2	BPB_Signature	AA55h	

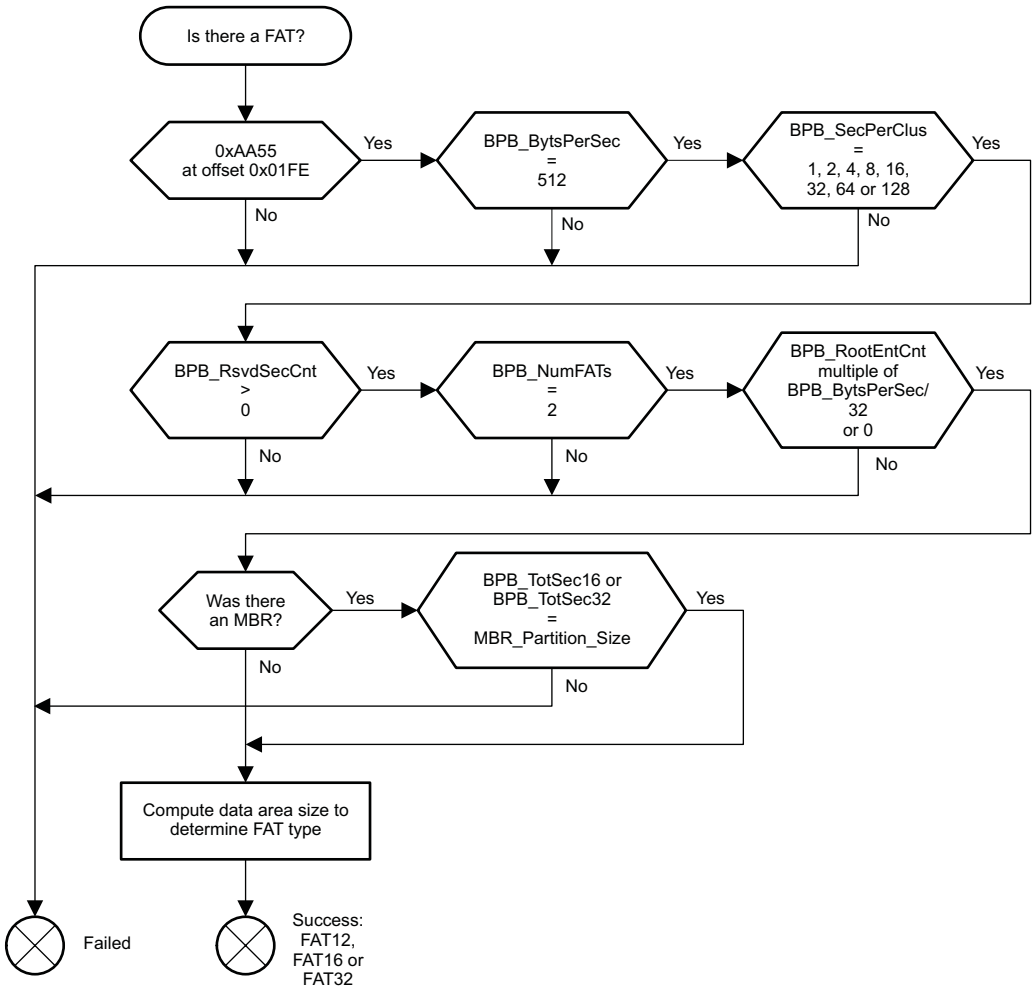
To check whether or not a sector holds a valid FAT12/16/32 partition, only fields starting with BPB can be checked as they are mandatory. The fields starting from offset 0024h to 01FDh cannot be used for the check as they will differ if using FAT12/16 or FAT32. The procedure is described in Figure 30. First the ROM Code checks if the *BPB_Signature* is equal to AA55h. Then it checks some fields which must have some specific values (*BPB_BytsPerSec, BPB_SecPerClus, BPB_RsvdSecCnt, BPB_NumFATs, BPB_RootEntCnt*) If the geometry of the device is known (valid CHS for device size < 4Gbytes) then it is compared against *BPB_SecPerTrk* and *BPB_NumHeads* fields. If an MBR was found before, the partition size is also checked:

The field *BPB_ToSec16* is used if the total number of sectors is below 65518 (in this case *BPB_TotSec32*=0), otherwise *BPB_TotSec32* is used (*BPB_TotSec16*=0). The partition sector offset is also checked: *BPB_HiddSec = MBR_Partition_Offset* (if this value is not 0 as some operating systems do not update this field correctly). The last step is to decide which type of FAT file system it is. The ROM Code computes the number of clusters in the Data Area part of the partition:

Where *Nb clusters* is given by the size of the Data Area:

Copyright © 2011, Texas Instruments Incorporated

Figure 26-22. FAT Detection Procedure



26.1.7.2.6.7.3 FAT12/16/32 Root Directory

The next task for the ROM Code is to find the booting file named “MLO” inside the Root Directory of the FAT12/16/32 file system. The file is not searched in any other location.

For a FAT12/16 file system, the Root Directory has a fixed location which is cluster 0. For a FAT32 file system, its cluster location is given by *BPB_RootClus*. The general formulae to find the sector number (relative to device sector 0, not partition sector 0) of a cluster is given by:

$$Cluster_{sector} = BPB_RsvdSecCnt + BPB_NumFATs \times BPB_FATSz + Cluster \times BPB_SecPerClus$$

Note: BPB_FatSz is BPB_FatSz16 for FAT12/16 or BPB_FatSz32 for FAT32

Note: the *BPB_HiddSec* field can contain 0 even though the FAT file system is located somewhere other than on sector 0 (floppy-like). The ROM Code actually uses the partition offset taken from the MBR instead of this field which can be wrong. If no MBR was found (floppy-like) the value 0 is used.

Each entry in the Root Directory is 32 bytes long and hold information about the file, i.e. filename, date of creation, rights, cluster location etc. This is described in Table 26-24.

The ROM Code checks each entry in the Root Directory until either the booting file is found or the entry is empty (first byte is 00h) or when the end of the Root Directory has been reached. Entries with ATTR_LONG_NAME attribute (LFN) and with first byte at E5h (erased file) are ignored. When found, the first cluster offset of the file is read from the DIR_FstClusHi/DIR_FstClusLo fields.

Copyright © 2011, Texas Instruments Incorporated

There is a slight difference between FAT12/16 and FAT32 when handling the Root Directory. On FAT12/16, this directory has a fixed location (see above) and length fixed by *BPB_RootEntCnt* which is the total number of 32 bytes entries. Handling this directory is therefore straight forward. On FAT32, the Root Directory is like a standard file, the File Allocation Table (FAT) has to be used in order to retrieve each sector of the Directory. The way the FAT is handled is described in the next paragraph.

Table 26-24. FAT Directory Entry

Offset	Length[bytes]	Name	Description	
0000h	11	DIR_Name	Short Name (8+3)	
000Bh	1	DIR_Attr	File Attributes:	
			ATTR_READ_ONLY	01h
			ATTR_HIDDEN	02h
			ATTR_SYSTEM	04h
			ATTR_VOLUME_ID	08h
			ATTR_DIRECTORY	10h
			ATTR_ARCHIVE	20h
			ATTR_LONG_NAME	ATTR_READ_ONLY | ATTR_HIDDEN | ATTR_SYSTEM | ATTR_VOLUME_ID
000Ch	1	DIR_NTRes	Reserved, set to 00h	
000Dh	1	DIR_CrtTimeTenth	Millisecond stamp at file creation	
000Eh	2	DIR_CrtTime	Time file was created	
0010h	2	DIR_CrtDate	Date file was created	
0012h	2	DIR_LstAccDate	Last Access date	
0014h	2	DIR_FstClusHi	High word of this entry's first cluster number	
0016h	2	DIR_WrtTime	Time of last write	
0018h	2	DIR_WrtDate	Date of last write	
001Ah	2	DIR_FstClusLo	Low word of this entry's first cluster number	
001Ch	4	DIR_FileSize	File size in bytes	

26.1.7.2.6.7.4 FAT12/16/32 File Allocation Table

The ROM Code needs to read the FAT in order to retrieve sectors either for the booting file or for the Root Directory (in case the file system is FAT32).

There can be multiple copies of the FAT inside the file system (ROM Code supports only 2) located after the Boot Sector:

$FATn_{sector}$ = *BPB_HiddSec+BPB_RsvdSecCnt+BPB_FatSz x n*

Its size is given by *BPB_FATSz16* or *BPB_FATSz32*. The ROM Code checks each copy of the FAT if identical. In case the values are different, the ROM Code uses the value from the last FAT copy.

With FAT32 file system, the copy system can be disabled according to a flag located in *BPB_ExtFlags[7]*. If this flag is set then FAT *BPB_ExtFlags[3:0]* is used. In this case no verification is made by the ROM Code with other copies of FAT.

The FAT is a simple array of values each refering to a cluster located in the Data Area. One entry of the array is 12, 16 or 32 bits depending on the file system in use.

The value inside an entry defines whether the cluster is being used or not and if another cluster has to be taken into account. This creates a singly-linked chain of clusters defining the file. The meaning of an entry is described in Table 26-25.

Note: For compatibility reasons, clusters 0 and 1 are not used for files and those entries must contain FF8h and FFFh (for FAT12); FFF8h and FFFFh (for FAT16); ?FFFFFF8h and ?FFFFFFFh (for FAT32).

Copyright © 2011, Texas Instruments Incorporated

Table 26-25. FAT Entry Description

FAT12	FAT16	FAT32	Description
000h	0000h	?0000000h	Free Cluster
001h	0001h	?0000001h	Reserved Cluster
002h-FEFh	0002h-FFEFh	00000002h-?FFFFFEFh	Used Cluster; value points to next cluster
FF0h-FF6h	FFF0h-FFF6h	?FFFFFF0h-?FFFFFF6h	Reserved values
FF7h	FFF7h	?FFFFFF7h	Bad Cluster
FF8h-FFFh	FFF8h-FFFFh	?FFFFFF8h-?FFFFFFFh	Last Cluster in File

Note: FAT32 uses only bits [27:0], the upper 4 bits are usually 0 and should be left untouched.

When accessing the Root Directory for FAT32, the ROM Code just starts from the Root Directory Cluster entry and follows the linked chain to retrieve the clusters.

When the booting file has been found, the ROM Code buffers each FAT entry corresponding to the file in a sector way. This means each cluster is translated to one or several sectors depending on how many sectors are in a cluster (*BPB_SecPerClus*). This buffer is used later on by the booting procedure to access the file.

26.1.7.2.6.8 Pins Used

The list of device pins that are configured by the ROM incase of MMC boot mode are as follows. Please note that all the pins might not be driven at boot time.

Table 26-26. Pins Used for MMC0 Boot

Signal name	Pin Used in Device
clk	**mmc0_clk**
cmd	**mmc0_cmd**
dat0	**mmc0_dat0**
dat1	**mmc0_dat1**
dat2	**mmc0_dat2**
dat3	**mmc0_dat3**

Table 26-27. Pins Used for MMC1 Boot

Signal name	Pin Used in Device
clk	gpmc_csn1
cmd	gpmc_csn2
dat0	gpmc_ad0
dat1	gpmc_ad1
dat2	gpmc_ad2
dat3	gpmc_ad3

26.1.7.2.7 SPI

SPI EEPROMs or SPI flashes have an EEPROM or NOR flash backend and they connect to the device using the serial SPI protocol.

These devices typically operate in three stages: the command stage, the address stage and the data transfer stage. The command is usually an 8 bit value followed by the address (depending on the size of the device) followed by the data to be read or written.

Because of the need for fewer pins, these devices are comparatively inexpensive, easy for board layout, and are the devices of choice when cost, complexity and form factor are critical considerations.

Copyright © 2011, Texas Instruments Incorporated

26.1.7.2.7.1 Features

- Supports 12-MHz clock (50% duty cycle)
- Supports only SPI Mode 3 (clock polarity = 1, clock phase = 1)
- Supports only 24 bit addressable EEPROMs
- Supports only 4-pin SPI mode (CS, CLK, Serial Input, Serial Output)
- The boot devices must be connected to chip select 0 and must support the read command (03h)
- The boot image is copied into internal memory and then executed.

26.1.7.2.7.2 Initialization and Detection

The ROM Code initializes the SPI controller, pin muxing and clocks for communicating with the SPI device. The controller is initialized in Mode 3 and the clock is setup to operate at 12 MHz. There is no specific device identification routine that is executed by the ROM code to identify whether a boot device is preset or not. If no SPI device is present, the sector read will return only 0xFFFFFFFF and the SPI boot will be treated as failed.

26.1.7.2.7.3 SPI Read Sector Procedure

The ROM Code reads SPI data from the boot device in 512 byte sectors. For each call to the SPI Read Sector routine, the SPI Read Command (0x03) is sent along with the 24 bit start address of the data to be read.

Form the next iteration onwards, a dummy value is transmitted on the master out line and the data is received on the master in line. This needs to be done because SPI protocol always operated in full duplex mode. The dummy data transmitted by the ROM is the Read Command appended to the start address. The data from the boot device is received MSB first.

As the A8 is a little-endian processor, and SPI operates in a big-endian format, this means that while writing to the flash, care needs to be taken to write the image in a big-endian format. This way we can avoid doing the endian conversion at boot time, thus improving boot performance.

26.1.7.2.7.4 Pins Used

The list of device pins that are configured by the ROM incase of SPI boot mode are as follows. Please note that all the pins might not be driven at boot time.

Table 26-28. Pins Used for SPI Boot

Signal name	Pin Used in Device
cs	spi0_cs0
miso	spi0_d0
mosi	spi0_d1
clk	spi0_sclk

26.1.7.3 Blocks and Sectors Search Summary

Table 26-29 summarizes numbers of blocks and sectors which are searched during the memory booting from devices requiring image shadowing. NAND is organized with blocks, which are erasable units.

Table 26-29. Blocks and Sectors Searched on Non-XIP Memories

Memory	Maximum Number of Blocks Checked	Number of Sectors Searched
NAND	first 4	Number of sectors in one block(1)
SPI, eMMC/eSD and MMC/SD cards (raw mode)	first 4	1

(1) Depends on NAND geometry

Copyright © 2011, Texas Instruments Incorporated

Regarding MMC/SD card booting in FAT mode, the file system area is searched for one file.

26.1.8 Peripheral Booting

26.1.8.1 Overview

The ROM Code can boot from four different peripheral interfaces:

- EMAC: 1000/100/10 Mbps Ethernet, using standard TCP/IP network boot protocols BOOTP and TFTP
- USB: Full speed, client mode
- UART: 115.2Kbps, 8 bits, even parity, 1 stop bit, no flow control

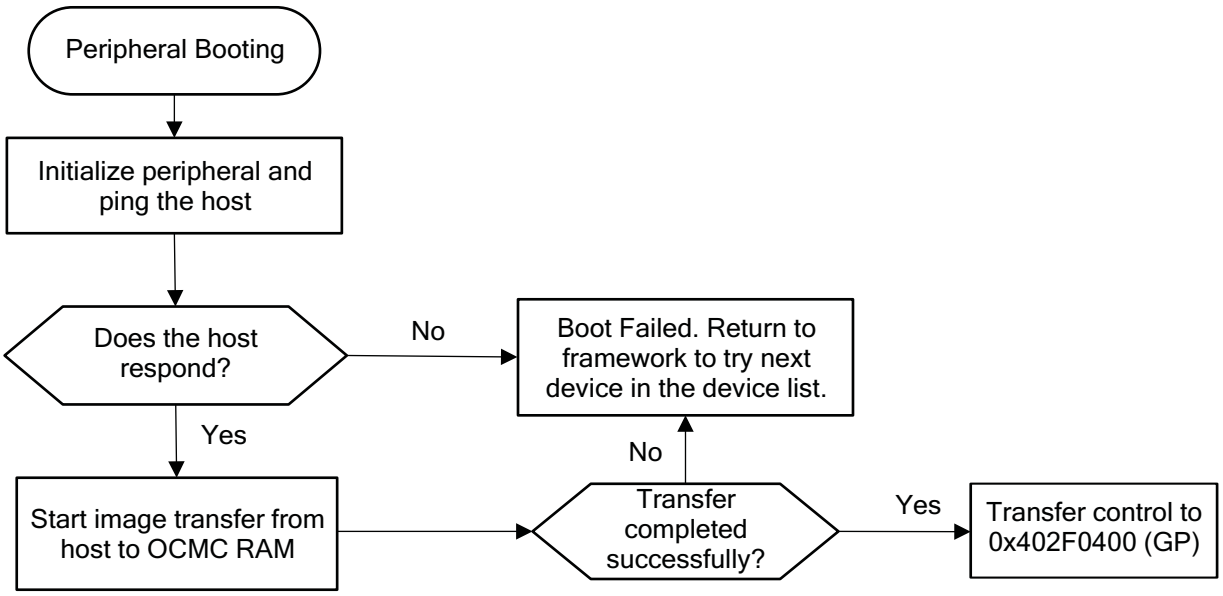
The purpose of booting from a **peripheral interface** is to download a **boot image** from an external host (typically a PC). This booting method is mostly used for programming flash memories connected to the device (e.g. in the case of initial flashing, firmware update or servicing).

26.1.8.2 Boot Image Location and Size

The boot image is downloaded directly into internal RAM at the location 0x402F0000 on GP devices. The maximum size of downloaded image is 110 KB.

26.1.8.3 Peripheral Boot Procedure Overview

Figure 26-23. Peripheral Booting Procedure



26.1.8.4 EMAC Boot Procedure

26.1.8.4.1 Device Initialization

- EMAC boot uses the CPGMAC port 1 of the device.
- Supports connection to external Ethernet PHY using the MII, RMII, RGMII and MDIO pins, based on SYSBOOT pin settings.
- Device uses EFUSE register MAC_ID0 for Ethernet MAC address of the device.
- Device detects if the PHY is alive on the MDIO interface and
  - Reads the STATUS register to check if Ethernet link is active
  - Reads the CONTROL register to detect the auto-negotiated mode of operation
    - Is the mode full-duplex or half duplex

Copyright © 2011, Texas Instruments Incorporated

- Speed of operation, 1000/100/10 Mbps.

– Waits for five seconds for auto negotiation to complete before timing out.

26.1.8.4.2 BOOTP (RFC 951)

The device then proceeds to obtain the IP and Boot information using BOOTP protocol. The device prepares and broadcasts the BOOTP message that has the following information:

- Device MAC address in “chaddr” field – to uniquely identify the device to the server.
- “vender-class-identifier” option number 60 (RFC 1497, RFC 1533). Servers could use this information to identify the device type. The value present is "**AM335x ROM v1.0**". (Note: Version may change in future devices.)
- “Client-identifier” option number 61 (RFC 1497, RFC 1533). This has the **ASIC-ID** structure which contains additional info for the device.

The device then expects a BOOTP response that provides the following information for the booting to proceed

- Device IP address from “yiaddr” field
- Subnetmask from extended option 1 (RFC 1497, RFC 1533)
- Gateway IP from extended option number 3 (RFC 1497, RFC 1533) or from “giaddr” field of BOOTP response.
- Boot image filename from “file” field
- TFTP server IP address from the “siaddr” field

Timeouts and retries

- Exponentially increasing timeouts starting from 4s, doubling for each retry.
- 5 retries

26.1.8.4.3 TFTP (RFC 1350)

After a successful BOOTP completion, the device initiates the TFTP download of the boot image into SRAM. The device has the capability to reach TFTP server within the local subnet or outside, though the gateway.

Timeouts and retries:

- Timeout of 1s to receive a response for the READ request
- 5 retries for the READ request
- Retries are managed by server once data transfer starts (server re-sends a data packet if the ACK was not received within a timeout value)
- Device has a 60s timeout to complete the data transfer, to handle the scenario if the server dies in the middle of a data transfer

26.1.8.4.4 Pins Used

The list of device pins that are configured by the ROM incase of EMAC boot mode are as follows. Please note that all the pins might not be driven at boot time.

Table 26-30. Pins Used for EMAC Boot in MII Mode

Signal name	Pin Used in Device
col	mii1_col
crs	mii1_crs
rx_clk	mii1_rxclk
rxd0-rxd3	mii1_rxd0-rxd3
rxdv	mii1_rxdv
rxerr	mii1_rxerr
tx_clk	mii1_txclk
txd_0-txd3	mii1_txd0-txd3
txen	mii1_txen
mclk	mdio_clk
mdio	mdio_data

Table 26-31. Pins Used for EMAC Boot in RGMII Mode

Signal name	Pin Used in Device
rxclk	mii1_rxclk
rxctl	mii1_rxdv
txclk	mii1_txclk
txctl	mii1_txen
rxd0	mii1_rxd0 – rxd3
txd0	mii1_txd0 –txd3
mclk	mdio_clk
mdio	mdio_data

Table 26-32. Pins Used for EMAC Boot in RMII Mode

Signal name	Pin Used in Device
refclk	mii1_refclk (driven by SOC)
crs	mii1_crs
rxerr	mii1_rxerr
txen	mii1_txen
rxd0	mii1_rxd0 – rxd1
txd0	mii1_txd0 – txd1
mclk	mdio_clk
mdio	mdio_data

26.1.8.4.5 SYSBOOT Pins

Some of the SYSBOOT pins have special meanings when EMAC boot is selected.

Table 26-33. Ethernet PHY Mode Selection

SYSBOOT[7:6]	PHY Mode
00b	MII
01b	RMII
10b	RGMII with internal delay

Table 26-33. Ethernet PHY Mode Selection (continued)

SYSBOOT[7:6]	PHY Mode
11b	RGMII without internal delay

26.1.8.5 UART Boot Procedure

26.1.8.5.1 Device Initialization

- UART boot uses UART0.
- UART0 is configured to run at 115200 baud, 8-bits, even parity, 1 stop bit and no flow control.

26.1.8.5.2 Boot Image Download

- UART boot uses x-modem client protocol to receive the boot image.
- Utilities like hyperterm, teraterm, minicom can be used on the PC side to download the boot image to the board
- With x-modem packet size of 1K throughout is roughly about 4KBytes/Sec.
- The ROM code will ping the host 10 times in 3s to start x-modem transfer. If host does not respond, UART boot will timeout.
- Once the transfer has started, if the host does not send any packet for 3s, UART boot will time out
- If the delay between two consecutive bytes of the same packet is more than 2ms, the host is requested to re-transmit the entire packet again
- Error checking using the CRC-16 support in x-modem. If an error is detected, the host is requested to re-transmit the packet again.

26.1.8.5.3 Pins Used

The list of device pins that are configured by the ROM incase of UART boot mode are as follows. Please note that all the pins might not be driven at boot time.

Table 26-34. Pins Used for UART Boot

Signal name	Pin Used in Device
rx	uart0_rxd
tx	uart0_txd

26.1.8.6 USB Boot Procedure

26.1.8.6.1 Device Initialization

The ROM Code supports booting from the USB interface under the following conditions:

- Using the High Speed USB OTG (USBOTGHS) IP through USB0 interface.
- USB operates in Full Speed, Client mode.
- USB will operate only in device powered mode.
- **Integrated transceiver** (through UTMI).
- The enumeration default timeout is **3s** (Timeout Usb).

Even though using an OTG capable hardware, the ROM Code does not handle any OTG specific feature.

26.1.8.6.1.1 Overview

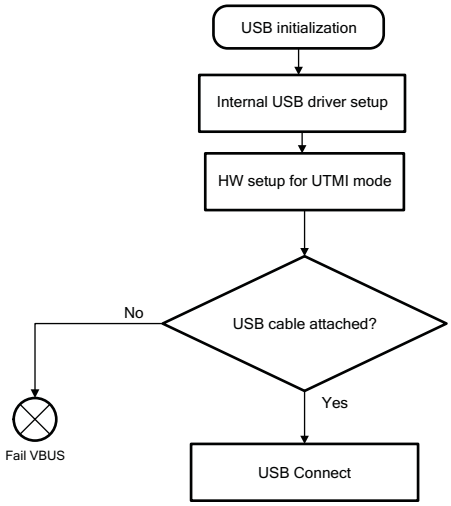
In case of boot from USB is chosen by the SYSBOOT pin configuration:

- The USBOTGHS hardware and PRCM clocks are configured for UTMI mode

Copyright © 2011, Texas Instruments Incorporated

- The ROM Code continues with the USB procedure only if the USB cable is detected present (i.e. VBUS is detected at transceiver level and communicated as such through the UTPI traffic). If not, the initialization procedure is aborted.
- The ROM code implements the RNDIS class driver
- From users perspective, USB boot is indistinguishable from Ethernet boot.
- The USB initialization procedure is shown in Figure 26-24.

Figure 26-24. USB Initialization Procedure



26.1.8.6.1.2 Enumeration Descriptors

The device descriptor parameters which are used during enumeration are listed in Table 26-35. The default Vendor ID and Product ID can be automatically overridden by the customer by programming the Efuses that are used to store these values.

Table 26-35. Customized Descriptor Parameters

Parameter	Size [bytes]	TI Default Values
Device ID code	2	0000h
Device Class	1	02h
Device Sub-Class	1	FFh
Device Protocol	1	FFh
Manufacturer	String	“Texas Instruments”
Product	String	“USBRNDIS”
Serial number	String	“N/A”

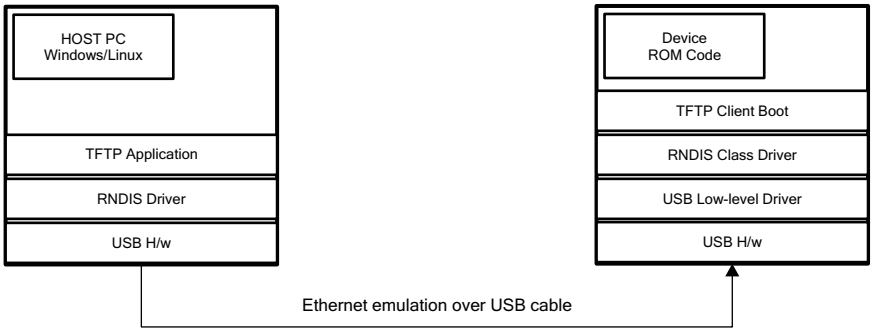
.

26.1.8.6.2 Image Download Procedure

- The device supports USB client boot only.
- The ROM implements as RNDIS class driver, so the device enumerates as an ethernet port.
- Standard RNDIS drivers present on Linux and Windows are picked up during the enumeration, no special drivers need to be installed.
- Once the enumeration is complete, the customer can download the boot image using any standard TFTP server application.

Copyright © 2011, Texas Instruments Incorporated

Figure 26-25. Image Transfer for USB Boot



26.1.8.6.3 Pins Used

The list of the device pins that are configured by the ROM incase of USB boot mode are as follows. Please note that all the pins might not be driven at boot time.

Table 26-36. Pins Used for USB Boot

Signal name	Pin Used in Device
dm	usb0_dm
dp	usb0_dp
id	usb0_id
vbus	usb0_drvvbus

26.1.8.7 ASIC ID structure

The ASIC ID size is 58 Bytes for UART and 81 Bytes for others. The fields of this structure are unused. This structure is included purely for legacy purposes.

26.1.9 Image Format

26.1.9.1 Overview

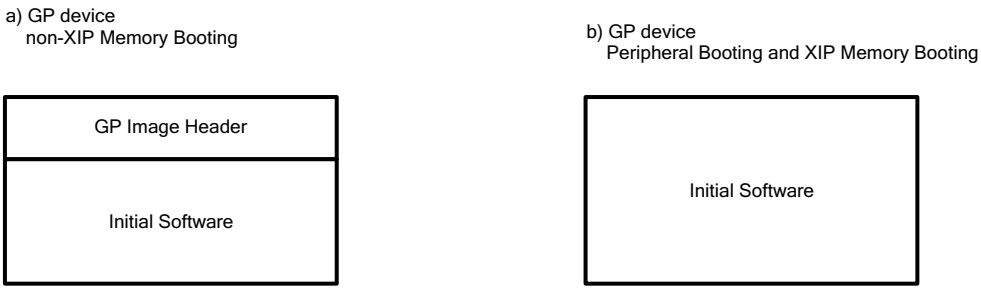
All preceding sections describe how the ROM Code searches and detects a boot image from a memory or a peripheral device type. This chapter describes the format of the boot image itself.

A boot image is basically made out of two major parts:

- The software to execute
- A header containing the destination address and size of the image for non XIP memory devices

The mandatory section of a boot image contains the software which will be loaded into the memory and executed. An overview of the image formats is shown in Figure 26-26:

Figure 26-26. Image Formats on GP Devices



Copyright © 2011, Texas Instruments Incorporated

a) GP non - XIP Memory Booting

Used for memories which require shadowing (e.g. MMC). Image must begin with a GP header which contains information on image size and destination address.

b) GP Peripheral Booting and XIP Memory Booting

When memory device is of XIP type (e.g. NOR) the GP header is not needed and the image can contain code for direct execution. . The same image format is used for peripheral booting (where the code is transferred to internal RAM).

26.1.9.2 Image Format for GP Device

When the booting memory device is non-XIP (e.g. MMC) the image must contain a small header (referred as GP header) with the size of the software to load and the destination address where to store it.

The GP header is not needed when booting from an XIP memory device (e.g. NOR) or in case of peripheral booting. In this case, the peripheral or memory booting image starts directly with executable code.

Table 26-37. GP Device Image Format

Field	non XIP device	XIP device	Size[bytes]	Description
	Offset	Offset		
Size	0000h	-	4	Size of the image
Destination	0004h	-	4	Address where to store the image / code entry point
Image	0008h	0000h	x	Executable code

Note: The “Destination” address field stands for both:

- Target address for the image copy from the non-XIP storage to the target XIP location (e.g., internal RAM or SDRAM)
- Entry point for image code

In other words the user must take care to locate the code entry point to the target address for image copy.

26.1.10 Code Execution

26.1.10.1 Overview

One of the early steps of the Public ROM Code execution is to search for a boot image from the requested medium (configured by the SYSBOOT pins) and copy it to RAM if needed. If the device is of GP type and boot interface is non-XIP then the image is simply copied to the provided destination address (internal or external RAM) and then executed. If the boot interface is of XIP type then the image copy is not needed and execution is directly given to the XIP memory.

26.1.10.2 Execution

The image is executed at the time the ROM Code performs the branch to the first executable instruction inside the Initial SW. For a **GP Device** in non-XIP the execution address is the first word after the GP header. The branch is performed in public ARM supervisor mode. The R0 register points to the Booting Parameters structure which contains various information about the booting execution. Table 26-38 details this structure.

Copyright © 2011, Texas Instruments Incorporated

Table 26-38. Booting Parameters Structure

Offset	Field	Size[bytes]	Description
00h	Reserved	4	Reserved
04h	Memory booting device descriptor address	4	Pointer to the memory device descriptor that has been used during the memory booting process
05h	Current Booting Device	1	Code of device used for booting 00h – void, no device 01h – XIP MUX1 memory 02h – XIPWAIT MUX 1 (wait monitoring on) 03h – XIP MUX2 memory 04h – XIPWAIT MUX 2 (wait monitoring on) 05h – NAND 06h – NAND with I2C 08h – MMC/SD port 0 09h – MMC/SD port 1 15h – SPI 41h – UART0 44h – USB 46h – CPGMAC0
06h	Reset Reason	1	Current reset reason bit mask (bit=1-event present)[0] – power-on reset [1] – global software reset [3] – Reserved [4] – MPU watchdog reset [5] – Reserved [6] – external warm reset Other bits – reserved
07h	Reserved	1	Reserved

26.1.11 Wakeup

26.1.11.1 Overview

The device supports a comprehensive set of low-powered states to meet aggressive power budget requirements. The different low-power modes supported, from the lowest power consumption state to the highest power consumption state are

- RTC Only
- Deep Sleep 0
- Deep Sleep 1
- Deep Sleep 2
- Standby
- Active

Of these states, the ROM code come into the picture only in the first three, as the A8 registers (particularly the PC) are preserved in all the other states. So for these modes, on wake up, execution will resume from the next instruction following the WFI.

In the RTC only mode, the ROM code involvement is trivial, as a wakeup from the RTC only mode, for the ROM perspective, is indistinguishable from a power on reset. In Deep Sleep 0 and Deep Sleep 1 state, it is the ROM codes responsibility to detect wakeup has occurred, and branch to a user defined return address, rather than doing a full boot.

Copyright © 2011, Texas Instruments Incorporated

26.1.11.2 Wakeup Booting by ROM code

In this device, when the A8 is in OFF mode, execution begins from the reset vector on wakeup. As the reset vector lies in the ROM code, the ROM code is the first software entity that takes control of the A8 on a wakeup.

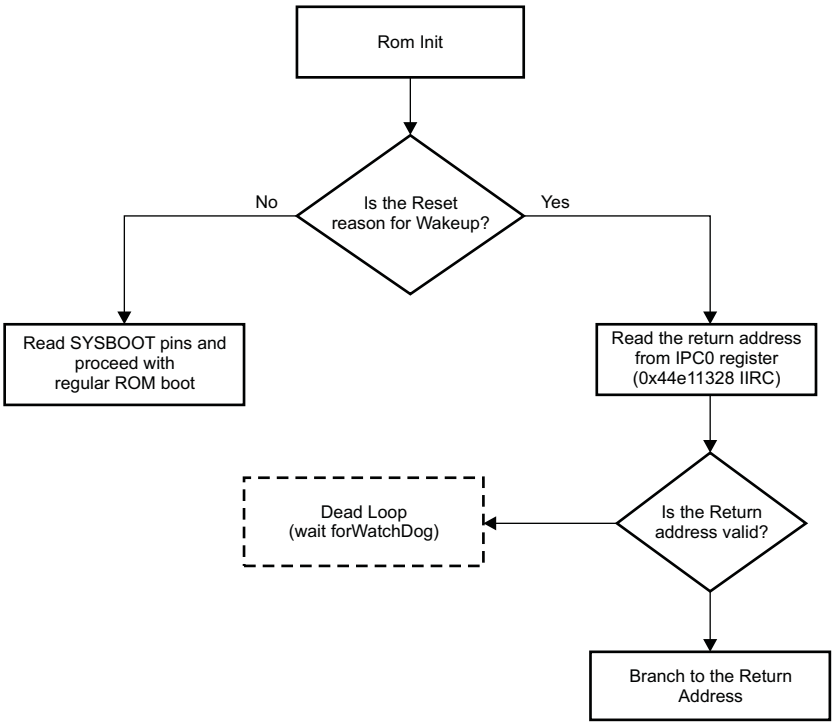
It must be noted here that in the device, in all the modes other than RTC only, the A8 internal SRAM and the L3 OCMC RAM are held in retention. This is a fundamental assumption of the ROM code. As the contents of these RAMs are not lost in the Deep Sleep modes, it is possible to return to a location in these memories.

This does away with the need of the ROM having to restore PLL and EMIF settings, which would have been needed if the ROM had to return to an DRAM address, as DRAM is held in self refresh. The job of dialing up the PLLs and restoring EMIF and other peripheral register values is the responsibility of the user code. The recommendation is that such restoration code be placed in the OCMC RAM.

In the past, having complex PLL and EMIF restore code in the ROM has made wakeup debugging very complicated. This has also traditionally been a source of many bugs, as the wakeup procedures are complicated and difficult to test exhaustively in pre-silicon.

The current architecture does away with these problems. The flow in the ROM on wakeup is kept simple and to the minimal. It only involves identifying that the reset reason is a Wakeup, and then branching to a return address, rather than proceeding with a full boot. This also helps in improving the time required to wakeup a system that is in Deep Sleep.

Figure 26-27. Wakeup Booting by ROM



26.1.12 Tracing

Tracing in the Public ROM Code consist in three 32 bit vectors for which each bit corresponds to a particular “way point” in the ROM Code execution sequence (see Table 26-4). Tracing vectors are initialized at the very beginning of the startup phase and updated all along the boot process.

There are two sets of tracing vectors. The first set is the current trace information (after cold or warm reset). The second set holds a copy of trace vectors collected at the first ROM Code run after cold reset. As a consequence after a warm reset it is possible to have visibility on the boot scenario that occurred during cold reset.

Revision History

Table A-1 lists the changes made from the original version of this document.

Table A-1. Document Revision History

Reference	Additions/Modifications/Deletions
Chapter 2, *Memory Map*	Updated Table 2-1, *L3 Memory Map*.
	Added PRM_IRQ register link to Table 2-2, *L4_WKUP Peripheral Memory Map*.
Chapter 3, *ARM MPU Subsystem*	Added first sentence to Section 3.1.3.1, *Clock Distribution*.
Chapter 4, *PRUSS*	Updated PRUSS integration figure and connectivity attributes table in Section 4.2, *Integration*.
	PRU
	Updated the PRU attributes table in Section 4.5.1, *Introduction*.
	Changed PRU2 references to PRUv2 in , *Basic Programming Model*.
Chapter 5, *SGX*	Updated SGX register content.
Chapter 6, *Interrupts*	Updated table and added note for Table 6-1, *Arm Cortex A8 Interrupts*.
Chapter 7, *Memory Subsystem*	Removed (i = 0 to 7) references.
	EMIF
	Updated memory device capacity listed in Section 7.3.1.1, *Features*.
	GPMC
	Updated features, including external memory clock performance and maximum addressing capability, in Section 7.1.1.1, *Features*.
	Updated signal list in Table 7-4, *GPMC Signal List*.
	Updated figures in Section 7.1.3.2, *GPMC Modes*.
	Updated Table 7-5, *GPMC Pin Multiplexing Options*.
	Updated GPMC address and data bus information in Section 7.1.3.3.7, *GPMC Address and Data Bus*.
	Added table note 3 that applies to GPMC_ECCj_RESULT in Table 7-55, *GPMC Registers*.
Chapter 8, *PRCM*	Updated information for cold and warm reset in Section 8.1, *Power Management and Clock Module (PRCM)*.
	Updated description of RTC-Only mode in Section 8.1.1.4.3.6, *RTC-Only*.
	Changed PRUSS RFT_CLK to CPTS_RFT_CLK in Figure 8-9, *Core PLL*.
	Added step to Section 8.1.1.7.3.2, *PORz Sequence*, for IO cell control
	Updated Table 8-24, *Reset Sources*.
	Updated Section 8.1.2.3.8, *CM_CPTS_RFT_CLKSEL Register*.
	Added PRM IRQ registers in Section 8.1.3.1.
Chapter 9, *Control Module*	Updated content on mode selection in Section 9.2, *Functional Description*.
Chapter 10, *Interconnects*	Updated Figure 10-1, *L3 Topology*, and Figure 10-2, *L4 Topology*.
Chapter 11, *EDMA*	Added table note to Table 11-23, *Direct Mapped*.
Chapter 12, *Touchscreen Controller*	Added note to Figure 12-1, *TSC_ADC Integration*.

Copyright © 2011, Texas Instruments Incorporated

Table A-1. Document Revision History (continued)

Reference	Additions/Modifications/Deletions
Chapter 14, *Ethernet Subsystem*	Updated Section 14.2, *Integration*. Updated Section 14.3.1.2.1, *Modes of Operation*. Updated Section 14.3.1.3, *Interrupts*, regarding receive/transmit interrupt masked interrupt status. Updated register references, including: • RX_EN→C*n*_RX_EN • TX_EN→C*n*_TX_EN • MISC_STAT→C*n*_MISC_STAT • TS_LOAD_VAL→CPTS_LOAD_VAL • TS_LOAD_EN→CPTS_LOAD_EN • TS_PUSH→CPTS_TS_PUSH • Event_Low→CPTS_EVENT_LOW • Event_High→CPTS_EVENT_HIGH • TS_Int_enable→ CPTS_INT_ENABLE • TS_Intstat_raw→CPTS_INTSTAT_RAW Added descriptions to Section 14.3.2, *CPSW_3G*, including Media Independent Interface (GMII) and Device Level Ring (DLR) Support. Added DLR Unicast entry to Section 14.3.2.7.1.4, *Unicast Address Table Entry*. Added Ingress, Egress, VLAN Aware and VLAN Unaware processes to Section 14.3.2.7.2, *Packet Forwarding Processes*. Added additional descriptions, including Section 14.3.2.11, *Packet Padding*, Section 14.3.2.10.3, *Rate Limit Mode*, and Section 14.3.4, *Command Idle*. Added Tx- and Rx-Statistics descriptions to Section 14.3.2.20, *CPSW_3G Network Statistics*. Updated Section 14.3.7, *Common Platform Time Sync (CPTS)*, including Figure 14-12, *CPTS Block Diagram*, and Section 14.3.7.2, *Time Sync Overview*. Updated types of sync events listed in Section 14.3.7.2.4, *Time Sync Events*, to include Hardware Time Stamp Push Event. Added description to Section 14.3.7.2.4.3, *Time Stamp Counter Half-Rollover Event*. Changed four RCLK periods in Section 14.3.7.3, *Interrupt Handling*, to eight CPTS_RFT_CLK periods. Updated type to R/W1toSet in Section 14.6.28, *RX_INTMASK_SET Register*. Updated type to R/W1toClr in Section 14.6.29, *RX_INTMASK_CLEAR Register*. Updated descriptions for PORT_NUMBER and SEQUENCE_ID in Section 14.7.11, *CPTS_EVENT_HIGH Register*.
Chapter 16, *USB*	Updated USB features in Section 16.1.1.1. Updated USB integration figure, Figure 16-1.
Chapter 20, *Timers*	**RTC** Updated procedures in Section 20.3.4, *Use Cases*.
Chapter 22, *McASP*	Updated number of serializer pins. Added McASP CFG and Data registers.
Chapter 26, *Initialization*	Updated content on dead loops and download image in Section 26.1.3, *ROM Memory Map*. Updated Figure 26-4, *RAM Memory Map*. Updated memory booting procedure in Section 26.1.5, *Booting*, for when a valid boot image is found. Added description to pins used for NOR boot in Section 26.1.7.2.2, *Pins Used*. Updated Figure 26-8, *Memory Booting*. Updated Figure 26-23, *Peripheral Booting Procedure*. Updated content on image format in Section 26.1.9, *Image Format*. Updated Figure 26-27, *Wakeup Booting by ROM*.

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, modifications, enhancements, improvements, and other changes to its products and services at any time and to discontinue any product or service without notice. Customers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All products are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its hardware products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by government requirements, testing of all parameters of each product is not necessarily performed.

TI assumes no liability for applications assistance or customer product design. Customers are responsible for their products and applications using TI components. To minimize the risks associated with customer products and applications, customers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any TI patent right, copyright, mask work right, or other TI intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information published by TI regarding third-party products or services does not constitute a license from TI to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. Reproduction of this information with alteration is an unfair and deceptive business practice. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

TI products are not authorized for use in safety-critical applications (such as life support) where a failure of the TI product would reasonably be expected to cause severe personal injury or death, unless officers of the parties have executed an agreement specifically governing such use. Buyers represent that they have all necessary expertise in the safety and regulatory ramifications of their applications, and acknowledge and agree that they are solely responsible for all legal, regulatory and safety-related requirements concerning their products and any use of TI products in such safety-critical applications, notwithstanding any applications-related information or support that may be provided by TI. Further, Buyers must fully indemnify TI and its representatives against any damages arising out of the use of TI products in such safety-critical applications.

TI products are neither designed nor intended for use in military/aerospace applications or environments unless the TI products are specifically designated by TI as military-grade or "enhanced plastic." Only products designated by TI as military-grade meet military specifications. Buyers acknowledge and agree that any such use of TI products which TI has not designated as military-grade is solely at the Buyer's risk, and that they are solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI products are neither designed nor intended for use in automotive applications or environments unless the specific TI products are designated by TI as compliant with ISO/TS 16949 requirements. Buyers acknowledge and agree that, if they use any non-designated products in automotive applications, TI will not be responsible for any failure to meet such requirements.
